The board of examiners of the American College of Chest Physicians announces that the next oral and written examinations for fellowship will be held in San Francisco on June 22. Candidates for fellowship in the College who would like to take the examinations should contact the Executive Secretary, American College of Chest Physicians, 500 North Dearborn Street, Chicago 10, Illinois.

Dr. Karl H. Pfuetze, Cannon Falls, serves as the governor of the College for the State of Minnesota, and Dr. John F. Briggs, Saint Paul, is the residing president of the Minnesota chapter.

AMERICAN CONGRESS OF PHYSICAL MEDICINE

The American Congress of Physical Medicine will hold its twenty-eighth annual scientific and clinical session August 28, 29, 30, 31 and September 1 at the Hotel Statler, Boston, Massachusetts. All sessions will be open to members of the medical profession in good standing with the American Medical Association. In addition to the scientific sessions, the annual instruction seminars will be held. These seminars will be offered in two groups. One set of ten lectures will consist of basic subjects and attendance will be limited to physicians. One set of ten lectures will be more general in character and will be open to physicians as well as to therapists who are registered with the American Registry of Physical Therapy Technicians or the American Occupational Therapy Association. Full information may be obtained by writing to the American Congress of Physical Medicine, 30 North Michigan Avenue, Chicago 2, Illinois.

NATIONAL CONFERENCE OF COUNTY MEDICAL SOCIETY OFFICERS

The seventh National Conference of County Medical Society Officers will be held at the Palace Hotel, San Francisco, on June 25, the day preceding the first meeting of the House of Delegates of the AMA. All physicians are urged to attend, particularly county medical society officers. Each address will be followed by a discussion period open to those in attendance.

The meeting will begin with registration at 9:00 a.m. and a call to order at 9:20 a.m. by Dr. A. M. Mitchell, chairman.

A questionnaire on socialized medicine will be given those in attendance, and the result will be announced before the lunch period.

Subjects, such as "How to Set Up a County Medical Society Record System," "How to Organize a Community Health Council," "Providing Special Benefits through County Medical Society Membership," will occupy the morning session.

The evening session will be devoted to a discussion of "The Third Party in the Practice of Medicine" (Insurance Companies, Hospital and Medical Care), "Hospitals and the Practice of Medicine."

This will be a grass roots conference, and physicians are urged to attend and participate.

INTERNATIONAL ACADEMY OF PROCTOLOGY

The second annual convention of the International Academy of Proctology will be held at the Bellevue Hotel in San Francisco, California, June 23, 24, 1950.

The scientific session will consist of the following papers: "Diverticulosis and Diverticulitis" by Edgar M. Scott, M.D., Birmingham, Ala.; "Surgery of Carcinoma of the Colon and Rectum" by Earl J. Halligan, M.D., Jersey City, N. J.; "Skin Covering of the Stoma Following Resection of the Rectum: Its Value in the Cases of Patients with Chronic Diarrhea" by H. A. Springer, M.D., Cincinnati, Ohio; "Psychosomatic Aspects of Proctology" by William Lieberman, M.D., Brooklyn, N. Y.; "Pectenosis, Illustrated by Colored Motion Picture and Lecture" by Manuel G. Spiesman, M.D., Chicago, Ill.; "The Nutritional Management of Patients with Colon Surgery" by Jacob J. Weinstein, M.D., Washington, D. C.; "The Preoperative Management of the Proctologic Patient" by Charles J. Weigel, M.D., River Forest, Ill.; "Diagnosis of Ano-Rectal Fistulae" by Emma L. Bellows, M.D., Southampton, L. I., N. Y.; "The Thermal Cutting Unit in Proctologic Surgery" by Alfred J. Cantor, M.D., Flushing, N. Y., and "Routine Proctoscopic Examinations of 1,000 Presumably Normal Healthy Individuals" by Caesar Portes, Chicago, Ill.

The annual banquet of the Academy will take place on Friday evening, June 23, 1950.

Further information concerning the convention and a copy of the program may be obtained by writing to the Secretary, Dr. Alfred J. Cantor, International Academy of Proctology, 43-55 Kissena Blvd., Flushing, N. Y.

VANCOUVER SUMMER SCHOOL CLINICS

Summer school clinics sponsored by the Vancouver Medical Association will be held in Hotel Vancouver from May 29 to June 2. The fee for the course is $10. Complete information can be obtained from Dr. Gordon C. Large, 203 Medical-Dental Building, Vancouver, B. C.

Speakers at the clinics will include Dr. A. L. Chute, pediatrician, Sick Children's Hospital, and associate

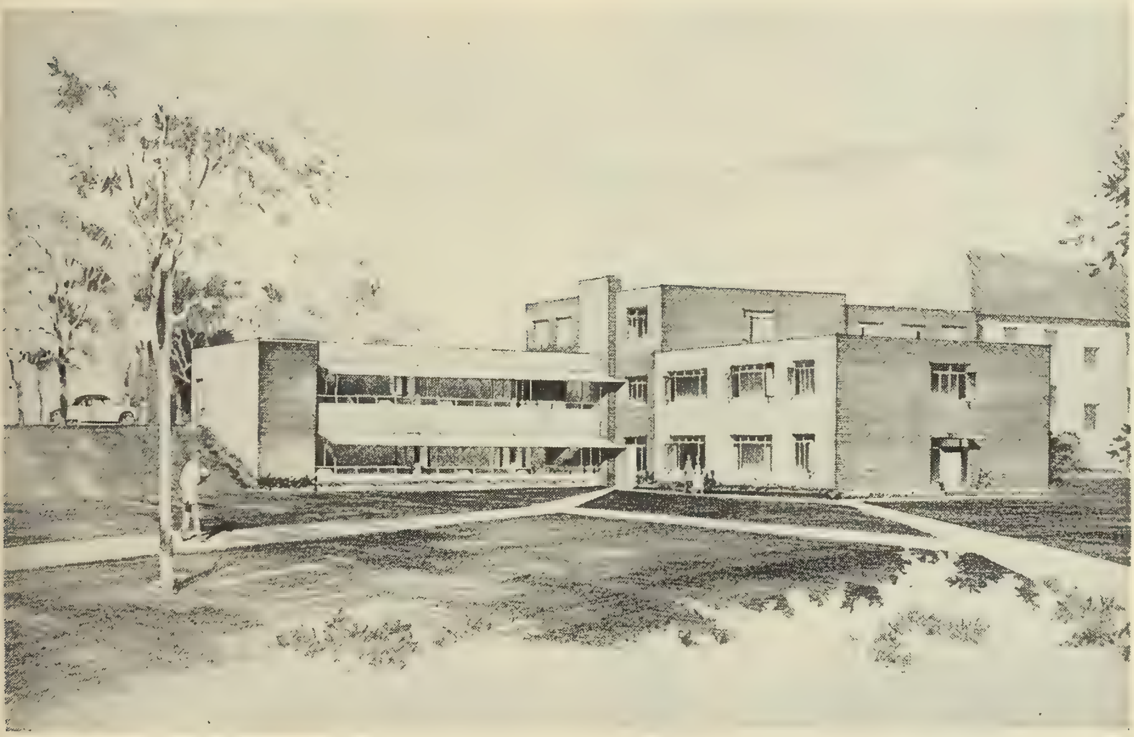
Announcing . . .

The First
NEUROLOGIC CENTER FOR CIVILIANS
in the Northwest

Governor Luther Youngdahl formally opened and dedicated our neurologic center and opened the doors to the public on February 12, 1950, thereby offering the following new services:

1) treatment of the hemiplegic patient
2) multiple sclerosis
3) retraining of speech disorders
4) paraplegia and other paralyses
5) ataxias



Qualified neurologists and neurosurgeons staff this center. The staff also includes qualified personnel who have been trained in special therapy, occupational therapy, corrective therapy and physical therapy.

GLENWOOD HILLS HOSPITALS

3501 GOLDEN VALLEY ROAD MINNEAPOLIS 22, MINNESOTA
Offering a High Standard of Facilities for 25 Years

BIRTCHER

BLENDTOME

Portable

Electrosurgical Unit

. . . a MODERN LOW-COST SURGICAL UNIT for all minor and various major surgery.

The Birtcher BLENDTOME is a surprisingly practical unit for office surgery. With this lightweight unit, you have *all* the electrosurgical procedures of major units—electro excision, desiccation, fulguration and coagulation. While not meant to be compared to a large hospital unit, the BLENDTOME has been successfully used in many TUR cases. Such facility indicates the brilliant performance of the BLENDTOME.

ALL 4 BASIC SURGICAL CURRENTS

1. *Tube Generated Cutting Current.*
2. *Spark-Gap Generated Coagulation Current.*
3. *A controlled mixed blend of both above currents on selection.*
4. *Mono-polar Oudin Desiccation-Fulguration Current.*

Never before has a surgical unit of such performance been offered at the low price of the Blendtome.

Write "Blendtome Folder" on your prescription blank or clip your letter head to this advertisement. Reprint of electrosurgical technic mailed free on request. Please indicate your specialty.

professor, Banting and Best Department of Medical Research, University of Toronto; Dr. Howard P. Lewis, professor of medicine, University of Oregon Medical School; Professor J. Chassar Moir, of the Nuffield Department of Obstetrics and Gynaecology, Radcliffe Infirmary, Oxford, England; Dr. R. L. Sanders, associate professor of clinical surgery, University of Tennessee; and Dr. Meyer Wiener, honorary consultant in ophthalmology, Bureau of Medicine and Surgery, United States Navy.

MINNEAPOLIS ACADEMY OF MEDICINE

Dr. Owen F. Robbins was elected president of the Minneapolis Academy of Medicine at a recent meeting of the organization. He will succeed Dr. C. O. Hansen in the office on July 1.

Other officers named include Dr. John Moe, vice president; Dr. John A. Haugen, secretary; Dr. Karl E. Sandt, treasurer, and Dr. Donald C. MacKinnon, recorder.

HENNEPIN COUNTY SOCIETY

Principal speaker at a meeting of the Hennepin County Medical Society in Minneapolis on April 3 was Dr. Robert G. Bloch, professor of medicine and chief of the division of preventable diseases at the University of Chicago. Dr. Bloch presented the fifteenth annual John W. Bell tuberculosis lecture, sponsored by the Hennepin County Tuberculosis Association. The title of his address was "The Relationship of Sarcoidosis to Tuberculosis."

RICE COUNTY SOCIETY

At a meeting of the Rice County Medical Society in Faribault on March 21, Dr. Donald J. Studer of Faribault was elected president of the organization. Dr. J. C. Belshe of Northfield was named secretary-treasurer.

The principal speaker at the meeting was Dr. Raymond N. Bieter, of the University of Minnesota, who presented a paper on "Chemotherapy."

ST. LOUIS COUNTY SOCIETY

The St. Louis County Medical Society held its regular monthly meeting at St. Mary's Hospital, Duluth, on May 11.

Principal speaker at the meeting was Dr. J. W. Conn, chief of the division of metabolism and endocrinology at the University of Michigan Hospital and associate professor at the University of Michigan Medical School. Dr. Conn spoke on the subject, "Metabolic Effects in Man of ACTH and Cortisone."

Another feature of the meeting was a report by Dr. M. O. Wallace, Duluth, chairman of the society's public relations committee.

Woman's Auxiliary

AUXILIARY PLANS ANNUAL MEETING

Mrs. H. E. Bakkila, President

It will be a great privilege for me not only as State President but also as a member of the St. Louis County Medical Auxiliary to welcome every one of you to the twenty-eighth Annual Meeting of the Woman's Auxiliary to the Minnesota State Medical association, in Duluth, June 12, 13 and 14. The Board of Directors and our hostesses, members of the St. Louis County Auxiliary, extend a most cordial invitation to all.

The Hotel Duluth will be Auxiliary Headquarters. The registration desk will open each day at 9:00 a.m.

On Monday at 10:30 a.m. the Executive Board meeting will be held at the Duluth Athletic Club. This will be followed at 1:00 p.m. by the annual Executive Board luncheon. At 3:00 p.m. all doctors' wives attending the convention will be guests at a tea at Northland Country Club honoring state officers. St. Louis county auxiliary members will be hostesses.

Monday evening the Minnesota State Medical association and the St. Louis County Medical Society are holding open house in the ballroom at the Hotel Duluth. The Physician's Symphony will play, and a square dancing group will entertain. There will be dancing from 9 to 12 p.m.

The Annual Meeting will be held Tuesday at 10:00 a.m. in the Hotel Duluth. The election of officers is at this meeting. The annual luncheon will be at 1:00 p.m. in the Harbor Room of the Flame. The new president will be awarded the president's pin. A style show will be presented by Oreck's store.

At 10:00 a.m. Wednesday, all visiting members are invited to be the guests of the St. Louis County Medical Auxiliary at the annual Roundup Breakfast at the Hotel Duluth.

The members of the St. Louis County Medical Auxiliary and all State officers and board members are anxious to have the wife of every physician in Minnesota present at this convention, so whether or not you are a member, do join in making this—our twenty-eighth annual meeting—a great success.

THE IMPORTANCE OF HEALTH DAYS

Mrs. H. F. Wahlquist, Health Day Chairman

Health Days, innovated in Minnesota, have almost become an institution in the state. Since the fall of 1947 when plans began for the first rural area Health Day, at least fifteen have been held in almost every trade area of the state. In addition, smaller health meetings have been held in numerous communities.

Health Days are speeding a growing realization that community health problems are everyone's concern. Because health is a community problem, and is interwoven in community living with other problems such as education and politics, any solution of one would make for progress in solving the others. But, to be successful in any undertaking, citizens of a community need to work together.

Health Days tend to get people to think about health problems. Through them the members of a community learn that health problems are their responsibility. During the meetings they are given accurate information, learn health truths and receive practical ideas on preventing disease. They are urged to look to reliable sources for information and are made aware that today the emphasis is on positive health—preventive medicine. They learn, too, that various factors like nutrition, recreation, housing, sanitation, immunization, clothing contribute to good health and that these are not the sole responsibilities of physicians, but the responsibilities of citizens of their respective communities. Finally they realize that these problems are handled best through public efforts in their own community.

First of all, successful Health Days are the product of many minds and hands. It is not strategic for any one organization in a community to try to put on a large Health Day alone. Health Days should be arranged and planned not by a few people, but by many people. They belong to everyone in the community and everyone must feel he has had some part in making them a reality, i.e., arranging the exhibits, planning the program, registering the people, writing the radio script, setting up the chairs or passing out the programs.

Furthermore, the success of Health Days relates directly to the workable organization which is set up to guide them, to the leaders participating in committee responsibility, to the publicity, and to the attractiveness of the program. Co-sponsored by the Minnesota State Medical Association, the State Department of Health and the Woman's Auxiliary to the state medical association, an initial planning meeting in the community must include representatives of all community organizations.

People who really do things should be selected as leaders in Health Day planning. Acting as heads of committees, leaders must show real interest and a willingness to give time and effort. They must know how to work with people. Publicity for Health Days can take many forms. It can be in the form of letters to heads of organizations, ministers, city officials, school superintendents; in the form of announcements in clubs, churches, schools; or through radio interviews and transcriptions. However, the most effective means of getting people awakened to the significance of Health Days is by enthusiastic personal contact—telling neighbors and friends about Health Days.

Programs for Health Days have various possibilities. Community needs vary greatly and programs must meet local needs. It is best to start at home and learn what the people can most readily absorb—consider if the locale is rural or urban, one county or many.

The program may be divided into sessions: morning,

IMPORTANCE OF HEALTH DAYS

(Continued from Page 524)

afternoon and evening. The type of community again should determine whether the program will begin in the morning and close at 4:30 p.m., with elaborate plans for an evening session, or whether just morning and afternoon sessions are better. Some communities may want to plan only an afternoon or an evening meeting.

Programs may include various methods of presenting material: round table discussions, a series of short ten-minute talks, one or two longer talks with a question-and-answer period, several half hour talks, health movies. They begin with a proper welcome and keynote address. If plans include an evening meeting, the speaker should be dynamic and, preferably, a prominent citizen of the state.

The members of the program committee should be representatives of various organizations of the community. They should be aware of community health needs, and have varied community interests. They should be experienced and realize what people in the community understand and want; enabling them to work out a meaningful program for their community.

Further program hints are:

1. Begin to plan the program two months before the Health Day.
2. Point up the objective of Health Day. Remember the first object is to study apparent needs, then to arouse people in the community to learn about those not evident. A definite plan of action to solve certain problems may evolve from an enthusiastic and "ready for action" audience.
3. Fill the program with a variety of health information and discussions about health problems.
4. Engage speakers outside of the community to bring diversity.
5. Put local people on the program to make good home town news and to help make the day belong to the community.
6. Use key people who are responsible for legislation and law enforcement as the presiding officers of the day.
7. Include someone from each county on the program if several counties combine to have a Health Day—a public health nurse, superintendent of schools, county commissioner, teacher, homemaker, minister, judge.
8. Plan a program in which a fair measure of success is assured. Start at the experience level of the people concerned—give them something they can do as individuals or parents in their community or home.
9. Remember no two Health Day programs can be alike.
10. Inform the speakers the amount of time they may have and insist they keep it.
11. Start on time, stop on time.
12. Stress the importance of everyone being friendly—provide a time for getting acquainted.
13. Keep the sessions peppy.

Many additional features may be included in Health

urn to enjoyable living, with
only limited restriction on their activities.

Despite a rise in the number of cases of coronary disease due to increasing age of the population, medical science is making notable progress in prolonging the lives of these people.

Your doctor today has at his disposal many new techniques and devices for checking on the condition of your heart and arteries. Periodic visits to him and observance of common sense routines in your daily living give the best assurance that you will benefit from geriatrics—the science of helping older people enjoy life longer.

While advances in medicine may add many years of physically comfortable living, your full enjoyment of those years calls for financial solvency. This is best attained through a sound program of savings and life insurance. Your N^WNL agent, paid not primarily for how much insurance he *sells* you but for what you *keep in force*, has a strong incentive to provide you with the insurance you need and can afford. He can help you plan wisely a financially comfortable future through life insurance.

FREE PAMPHLET: *"Consider Your Coronaries" describes what you can do to minimize the possibility or the effect of this heart disorder. Sent free on request.*

IMPORTANCE OF HEALTH DAYS

(Continued from Page 526)

Day plans. Voluntary health organizations are eager to co-operate. They seek earnestly the opportunity to co-operate and will set up exhibits and man their own booths. Noon sack lunches in smaller communities are helpful. They provide, while people are eating together, the surroundings for friendly visits among neighbors. Essay or poster contests on current health topics stimulate local school interest in Health Days and increase attendance. Band concerts give young people a chance to do something toward Health Day planning.

Through Health Days, citizens have learned many things. They have learned how to prevent wasteful duplication of effort. They have discovered their own local health needs and found out that, through their own local resources, they can do a good public health job. The speakers and movies have helped them substitute truth for mistaken and distorted ideas about health. Finally they have come to know one another better and enjoyed the privilege of working with one another for the good of their community.

It is important to recognize that Health Days are only the first step. What grows out of them is what counts. County health councils have been formed, food handlers' schools organized, county public health nurses employed, dental clinics held, weekly radio programs on health arranged, emotional health committees organized. Today these are carrying on where Health Days left off. Through these channels the community interest in health is being kept alive and functioning.

Great opportunities are open to wives of physicians today. The cause of medicine definitely needs support. Through untiring effort and co-operating, a contribution will be made toward public education in the closely related fields of medical science and medical economics.

SOUTHWESTERN AUXILIARY HEARS SPEAKER

Mrs. D. J. Halpern, President

Members of the Southwestern Medical Auxiliary heard Miss Laura Hegstad, Cancer Nursing Consultant, Minnesota Department of Health, speak on "How Can We Help in the Cancer Control Program in Our Communities?"

Miss Hegstad spoke at a dinner meeting on April 10 at Worthington.

The hostess was Mrs. F. L. Schade. She was assisted by Mrs. E. A. Kilbride, Mrs. P. J. Pankratz and Mrs. E. S. Schutz.

The great physicians of all time have understood that medicine is not a study of disease, but a study of man: an individual who is a member of a family and who is part of a community. . . . The purpose of medicine is to make available to all the people, in the greatest possible degree, the achievements of science as they relate to the promotion of health and to the prevention and treatment of disease.—W. G. Smillie, M.D., *New England J. Med.*, January 12, 1950.

In Memoriam

JAMES KERR ANDERSON

Dr. James Kerr Anderson of Minneapolis died on March 27, 1950 at the age of fifty-eight.

Dr. Anderson was born in East Liverpool, Ohio, July 11, 1891. He received his liberal arts degree from Washington and Jefferson College at Washington, Pennsylvania, in 1913 and his medical degree from Johns Hopkins Medical School in 1917.

He came to Minneapolis to intern at the Minneapolis General Hospital in 1917, after which he entered the Army in World War I as a First Lieutenant. After the war he spent the years 1920 to 1924 as a patient in Glen Lake, Sanatorium, after which he acted as superintendent of Pokegama Sanatorium for a year and of Sunnyrest Sanatorium at Crookston from 1925 to 1929. He then began practice in Minneapolis.

Dr. Anderson was a fellow of the American College of Surgeons, a fellow of the American Proctologic Society, a diplomate of the American Board of Surgery in Proctology, a member of the Minnesota Academy of Medicine, the Minneapolis Academy of Medicine and the Hennepin County Medical Society. He was a Clinical Associate Professor of Surgery at the University of Minnesota and a co-author with Dr. H. O. McPheeters of a book entitled "Injection Treatment of Varicose Veins and Hemorrhoids." He was also a past national president of the medical fraternity, Phi Beta Pi.

Dr. Anderson is survived by his widow, Clara; a daughter, Mrs. Robert Osgood of Arlington, Massachusetts, and his mother, Mrs. Nettie Anderson of Pittsburgh, Pennsylvania.

JOHN CURRER BARTON

Dr. John Currer Barton of Washington, D. C., died February 12, 1950, following an illness of several months.

Dr. Barton was born in Two Harbors, Minnesota, July 8, 1906, and attended the University of Minnesota Medical School from which he was graduated in 1934. After his internship at Milwaukee County Hospital he was on the staff of the Independence State Hospital, Independence, Iowa, for several years.

Holding a reserve commission since graduation he was called to active duty in 1940 and served five years, separating with the rank of colonel in command of the 131st General Hospital overseas. He then became medical consultant to the Claim Service of the Veterans Administration in St. Paul and was transferred to Washington in 1949.

Dr. Barton was a member of Acacia, Phi Beta Pi, Ramsey County Medical Society, Minnesota State Medical Association, the American Medical Association and the American Psychiatric Association.

He is survived by his wife, Helen Brockman Barton, who was also his classmate; a daughter, Sandra, and two sons, John and Craig, of Bethesda, Maryland.

Leo A. Nash, M.D.

WILLIAM K. FOSTER

Dr. William K. Foster, for many years a figure in athletics at the University of Minnesota and in Minneapolis high schools, died following a heart attack February 25, 1950.

Dr. Foster was born at White Plains, Alabama, December 1, 1878. He attended the University of Minnesota from which he obtained the degrees of LL.B., LL.M., A.B., M.B., and M.D., the last in 1920. He interned at the Minneapolis General Hospital.

He was medical examiner for Minneapolis high school athletics for twelve years and served as Dr. Cooke's assistant at the University of Minnesota for sixteen years. Gymnastics was his favorite sport, and he had just completed writing a book on the history of that activity at Minnesota.

Dr. Foster is survived by his widow, one daughter, Mrs. Willis E. Dugan of Minneapolis; four brothers, Dr. James M. Foster of Minneapolis and Dr. John, Mark and Oscar, all of Ruston, Louisiana, and two sisters, Mrs. Elizabeth Doss and Mrs. Eula Fuller, both of Ruston.

GEORGE DOUGLAS HEAD

Dr. George Douglas Head, dean of Minneapolis internists, died at his home, 55 Dell Place, on December 19, 1949, after fifty-three years of medical practice, in his eightieth year.

He was born in Elgin, Minnesota, on September 10, 1870. His parents, Mary Elizabeth Douglas and Newell Samuel Head, were of Scotch-English extraction. He received his elementary education in the schools of Plainview and Elgin, Minnesota. He graduated from Fargo high school and received his B.S. and M.D. degrees from the University of Minnesota in 1892 and 1895. He pursued postgraduate study under William Osler in 1902 at Johns Hopkins. In 1905 and 1908, he engaged in further postgraduate work at the University of Vienna and the University of Edinburgh.

His first early years, after graduation from medical school, were divided between assisting Dr. William Hunter, then head of the Department of Medicine at the University of Minnesota medical school, and building a general practice in southeast Minneapolis at the corner of Washington and Oak Street. After the inspiration of Sir William Osler's contact and teaching, Dr. Head decided to devote his life to the specialty of internal medicine, and thus became the first physician in Minneapolis to confine himself strictly to this field.

After completion of his medical course in 1895, he continued his academic career by serving his alma mater in the teaching capacities of Assistant in the Dispensary 1895-97; Instructor of Clinical Microscopy 1895-1906; Assistant Professor of Clinical Medicine and Microscopy 1905-10; and Associate Professor of Medicine 1910.

GEORGE DOUGLAS HEAD

(Continued from Page 530)

From 1902 to a year before his death, he engaged actively in the specialty of internal medicine, and his special interests were diseases of the heart and lungs. Current literature received some fifty-two scientific contributions, and he was the author of a monograph, "Concealed Tuberculosis," published by Blakiston. He will be well remembered for his diagnostic acumen, his careful painstaking physical examinations, and his kindly, and at times, remarkable patience—an attribute that endeared him to patients and students alike—for he was a great teacher in the art and science of medicine. In therapy, he was fundamentally a nihilist, holding that nature must be relied upon, and that simple drugs might be used to encourage her if they offered little or no risk of hampering her.

The last forty years of Dr. Head's life were greatly influenced by the development of diabetes mellitus in 1910, undoubtedly inherited from his mother who died of the disease. He was forced to give up his medical teaching at the University, resign from several public positions and curtail his social activities. At this time, he was convinced that he had no more than five to ten years to live. He adhered with Spartan tenacity to a Newburgh-Marsh high fat, high protein diet for the next twenty years, which kept up his body weight, almost eliminated the urinary sugar, but produced chronic ketonuria with acetone usually three to four plus. This, together with increased rest and daily regular physical exercise, enabled him to keep on with his professional work.

In 1918, Dr. Head and his diabetes volunteered for service in World War I, but he was rejected on three different occasions. Finally, in October of the same year, the Surgeon-General, desperate for doctors, accepted him for service within the continental limits. Dr. Head then served for eight months as Major and Chief of the Medical Service at the base hospitals in Camp Wheeler, Georgia, and Camp Devons, Massachusetts. It is an interesting sidelight that his army service with its regular hours and relative freedom from nerve tension proved to be of salutary effect on his disease. In 1921, Dr. Head contracted a mild virus encephalitis from which he recovered in a few months, but which left him with paralysis agitans in his later years. He first found it necessary to take insulin in 1930 when it probably saved his life, for diabetic coma set in as a result of a severe pyelonephritis associated with right kidney stones. In 1938, insulin and sulfathiazole enabled him to successfully undergo a right nephrectomy, and in the subsequent years, he found it necessary to take sulfadiazine once a week to curb his left pyohydronephrosis. Dr. Head's anginal syndrome started with mild transient attacks three years before his death. His blood pressure was always normal. He suffered three attacks of coronary thrombosis with the final lethal episode—a femoral artery embolus. The findings were substantiated by postmortem examination.

Dr. Head's honors were many, and he was a member of many scientific societies. He was president of the Hennepin County Medical Society in 1922 and the Min-

GEORGE DOUGLAS HEAD

(Continued from Page 532)

nesota State Medical Association in 1926. He was chief of staff of Abbott Hospital in 1928. His fraternities were Nu Sigma Nu, Delta Tau Delta, Sigma Xi, and Alpha Omega Alpha. However, one of his most cherished memories was his activity as founder and later as president of the Minnesota Society of Internal Medicine.

Dr. Head is survived by his wife, Sarabel Parry, his son, Douglas Parry, and five grandchildren.

CHARLES HARCOURT JOHNSON

Dr. Charles H. Johnson of Spring Valley, Minnesota, passed away March 16, 1950 at Worrall Hospital in Rochester.

Dr. Johnson was born January 26, 1886 in Spring Valley, Minnesota. He obtained his medical degree from the University of Illinois in 1912. He served as a Lieutenant in the Medical Corps of the Army in World War I.

Dr. Johnson was united in marriage to Lillian Low, February 7, 1912. He is survived by his widow and four children: Dr. Ross H. Johnson of Austin, Miriam Johnson of Los Angeles, Charles Wayne Johnson of Colome, South Dakota, and Dr. William D. Johnson of Spring Valley.

WALTER W. NAUTH

Dr. Walter W. Nauth, one of the founders of the Winona Clinic at Winona, Minnesota, died from a heart attack at Sarasota, Florida, on February 22, 1950.

Born in Mitchell, South Dakota, July 5, 1884, Dr. Nauth moved as a boy to Milwaukee and graduated from Marquette Medical School in 1907. He practiced in Minneiska, Minnesota, for nine years, Stanbaugh and Penboga, Michigan, each for a year. He became a medical officer in the army during World War I but in 1917 received an honorable medical discharge because of a heart lesion.

Dr. Nauth began practice in Winona in 1917 and in 1920 with Dr. E. S. Muir and Dr. E. M. McLaughlin founded the Winona Clinic. In recent years, because of a heart ailment, he spent much time in his workshop in the basement of the Clinic.

Dr. Nauth was a 32nd degree Mason and member of the Winona Scottish Rites bodies and of Osman Temple of the Shrine at Saint Paul. He was also a member of the Winona Elks Lodge, the Improved Order of Red Men, the Fraternal Order of Eagles, the Winona County medical society and the Minnesota State and American Medical Associations.

Dr. Nauth is survived by his widow, a son, Bernard, and four grandchildren.

ALBERT W. SHAW

Dr. Albert W. Shaw of Buhl, Minnesota, died April 16, 1950, in Virginia Municipal Hospital after an illness of eight weeks. He was seventy-nine years of age.

Dr. Shaw was born in Levant, Maine, February 25, 1871. He acquired his early education at Levant and in the grade schools and a preparatory school in Cambridge, Massachusets. He came to Minneapolis in 1888 and engaged in the grocery business to accumulate funds to acquire a medical education. He graduated from the University of Minnesot Medical School in 1899 and interned three years at Eveleth Hospital. On September 9, 1901, he went to Buhl as company physician for the Sharon Ore Company and the Drake-Stratton Company.

In September, 1918, he built a handsome brick hospital with modern laboratory facilities which was later sold to St. Louis County for use as a county institution for the chronically ill. He retired eighteen years ago from general practice and fifteen years ago moved to Virginia.

Dr. Shaw married Anne Laura Purdy of Logansport, Indiana, on September 24, 1902. She preceded him in death on November 24, 1947. Three children survive.

FRANK WILLIAM SPICER

Frank William Spicer, A.B., M.D., was born in Blairstown, Iowa, November 30, 1878. He died in Duluth, Minnesota, on January 21, 1950. Graduating from the University of Pennsylvania Medical School in 1908 and serving internship at the Methodist Hospital in Philadelphia, he practiced medicine for a period in Crystal Falls, Michigan. He moved to Duluth, Minnesota, in 1912 where, except for his service in the United States Army Medical Corps which included an assignment overseas, he spent the rest of his active career.

He received his preliminary education in Iowa and graduated from Coe College in 1899. He gave several years to teaching; first in Northfield, Minnesota, where he taught Greek and History in the high school. In 1903 he accepted the call and a teaching assignment in the Philippines, a period after the Spanish-American War when under American guidance a notable plan of advanced education was inaugurated. In later life he frequently referred to his experience in the Philippines and without question it greatly helped to broaden the life already capable of encompassing the best of our American traditions, scholastic, social, moral and intellectual. Frank's father was a doctor and it was his experience in the Philippines and later on visits to China, Japan and Guam that he developed the interest and the urge to return to the States and study medicine.

Frank Spicer was one of the first physicians in Northeastern Minnesota to devote all his time to internal medicine. He cemented interest in his field by obtaining membership in the American College of Physicians (Fellow 1922); membership in the Minnesota Society of Internal Medicine; and through his years of activity in establishing the medical staffs of both St. Mary's and St. Luke's Hospitals in Duluth. At one time he served as chief of medical service in each hospital and did much to wisely and conservatively guide his fellows. He was also active in the work of the American Legion and gave to the legion and to the rehabilitation of disabled veterans a fine personal service.

In 1939, he published "Trauma and Internal Disease" (J. B. Lippincott & Company.) To the writing of this work he gave several years of research and review of the extensive literature. The book has found a favorable reception among critics and a place in many private

and public medical libraries. He was a member of the First Presbyterian Church, in Duluth, where he met and married Madeline Miller, the church organist, in 1915. To them were born four children: Dr. Frank W. Spicer, Jr., Buffalo, New York; Richard G. Spicer, Duluth, Minnesota; Mrs. Thomas G. Bell, Jr., Duluth, Minnesota, and Mrs. Clark MacGregor, Wayzata, Minnesota. In addition, three grandsons and two granddaughters survive him.

Frank W. Spicer was an earnest, conscientious student and citizen all his life. In his later years he used to be commended for his very particular and specific guidance of an appreciative clientele, teaching them the while "to grow gracefully." In him they found the best of examples and the most wholesome of guidance.

E. L. Tuohy, M.D.

JULIUS R. STURRE

Dr. Julius R. Sturre, physician of Minneapolis and president of the Minnesota division of the Izaak Walton League of America, died March 28, 1950 at the age of fifty-five.

Dr. Sturre was born in St. Cloud, Minnesota, August 7, 1894. He attended Central High School in Saint Paul and obtained his M.D. degree from the University of Minnesota in 1918. After serving with Base Hospital 26 during World War I, he practiced for a short time in Saint Paul and in Watkins before coming to Minneapolis in 1926. He was mayor of Watkins from 1923 to 1926, and president of the Meeker County Medical Society in 1924.

Dr. Sturre, who had served on the national board of directors of the Izaak Walton League, became state president last December. He was for years interested in movements to conserve soil, eliminate water pollution and protect wild game. He was a member of the Minnesota Conservation Federation and a past president of the National Wild Life Federation and of the Fur, Fin and Feathers Club. He was a member of the Business and Professional Men's post of the American Legion, Knights of Columbus and of Phi Beta Pi, medical fraternity. He was also a fellow of the International College of Surgeons and a member of the Hennepin County medical society.

Dr. Sturre is survived by his wife, Winifred; a daughter, Mrs. Arthur Engstrom; a son, Richard; and his mother, Mrs. Gerhard Sturre of St. Cloud. One son, Julius, was tragically killed in 1940 at the age of sixteen in an automobile accident.

JOHN DOUGLAS WATSON

Dr. John D. Watson, a practitioner at Holdingford, Minnesota, from 1915 to 1940, passed away February 13, 1950, in a Saint Paul hospital.

Dr. Watson was born at Socorro, New Mexico, November 19, 1885. He attended high school in London, Ontario, and obtained his medical degree from the University of Western Ontario at London in 1907.

He practiced at Welton, Iowa, from 1907 to 1915 before moving to Holdingford. He served as a first lieutenant in the Army during World War I, having been stationed at Fort Douglas, Salt Lake City.

Dr. Watson is survived by his wife, Edith; a daughter, Mrs. Peter Holliday of Chicago; a son, Dr. William J. Watson of Saint Paul and a sister, Mrs. George Carmen of Battle Creek, Michigan.

Dr. Watson was a member of the Upper Mississippi Medical Society, the Minnesota State Medical Association and American Medical Association.

OLAF S. WERNER

Dr. Olaf S. Werner, for more than a half century a practitioner at Lindstrom, Center City and Cambridge, Minnesota, passed away March 24, 1950 at the home of his daughter, Mrs. Roy T. Sorensen, in Saint Paul.

Dr. Werner was born in Konga, Sweden, November 10, 1866. He received his Bachelor of Arts degree from Lund University in 1890. He came to the United States and continued his studies at Augustana College, Rock Island, Illinois, where he was ordained a Lutheran minister. He received his M.D. degree from Milwaukee Medical College in 1897. He was naturalized in 1898. He practiced in Manistique, Michigan, from 1897 to 1899, in Lindstrom, Minnesota, from 1899 to 1921, in Saint Paul from 1924 to 1928 and in Cambridge from 1928 to 1942.

Dr. Werner is survived by his wife, a son, Dr. Robert Werner of Los Angeles, and a daughter, Mrs. Floyd E. Brennen of Saint Paul.

✦ Of General Interest ✦

A method for locating a brain tumor by means of extremely high frequency sound waves has been developed in Minneapolis by Dr. John J. Wild and Dr. Lyle A. French, assistant professor of neurosurgery at the University of Minnesota.

The method makes use of an "ultrasonascope," which, when connected to radar equipment, sends ultrasonic pulses into tissue and then picks up their echoes as they bounce back. The echoes are converted into electrical impulses and made to appear as a fluorescent pattern on a screen. With tumor tissue denser than the tissue around it, the waves take a longer time to pass through the tumor and echo back. Differences in echo time can readily be seen on the screen.

Still in experimental stages, the method apparently produces no injury to the brain.

* * *

Dr. Gaylord Anderson, director of the University of Minnesota School of Public Health, has been elected chairman of a state poliomyelitis planning committee.

* * *

Dr. M. J. McKenna, Grand Rapids, attended the annual four-day clinical conference of the Chicago Medical Society which was held in Chicago early in March.

* * *

The Austin Clinic announced on March 21 that **Dr. H. P. Van Cleve,** formerly of Dodge Center, had become a member of the clinic staff. A graduate of the University of Minnesota Medical School, Dr. Van Cleve interned at Minneapolis General Hospital, then completed a residency at Swedish Hospital, Minneapolis. His addition to the Austin Clinic staff fills the vacancy created when Dr. Paul Hauser left the clinic on January 1 to resume postgraduate studies.

* * *

Dr. E. M. Hammes, Saint Paul, spoke on "The Medical Expert Witness" at the annual meeting of the Iowa State Medical Society in Burlington, Iowa, on April 24. His talk was presented with special reference to the work of the Medical Testimony Committee of the Minnesota State Medical Association.

* * *

Dr. H. H. Russ of Blue Earth has been invited to serve as a member of the National Cerebral Palsy Parents Advisory Council for one year. The honor was given the physician because of his work with the Spastic Club and the numerous speeches he has made on cerebral palsy problems. The council is appointed on an annual basis to act in an advisory capacity in the development of the national society's program.

* * *

Three Duluth physicians were on the program at the regional meeting of the American College of Surgeons in Winnipeg on April 3. The three were Dr. Arthur H. Wells, Dr. O. E. Sarff and Dr. Mark Tibbetts.

* * *

Dr. Harold W. Hermann, formerly of Caledonia, has moved to Minneapolis to practice in the field of pediatrics. Dr. Hermann was graduated from the University of Minnesota Medical School in 1946.

* * *

After forty-three years of practice in Bird Island, **Dr. Ralph C. Adams** announced his retirement from active practice late in March. His practice will be conducted until July 1 by Dr. George H. Mesker, formerly of Olivia but now staff member of the Cambridge State Hospital. Dr. Adams announced that on July 1 he will sell his practice to a young man who is currently completing his internship.

A graduate of the Jefferson Medical School in Philadelphia, Dr. Adams was one of the pioneer physicians in Bird Island and Renville County. Always interested in social, civic and fraternal activities, he helped to organize the Renville County Medical Society and participated in numerous local civic events. He has served as surgeon for the Milwaukee Railroad since 1909.

For several months prior to the anouncement of his retirement, Dr. Adams had been practicing only on a part-time basis due to ill health.

* * *

Dr. Lois A. Day, formerly on the staff of the Mayo Clinic, left Rochester late in March to become associated for six months in private practice in Saint Paul with Dr. Frank W. Quattlebaum and his wife, Dr. Jane Hodgson. A graduate of the University of Chicago, Dr. Day interned at University Hospitals, Minneapolis, and entered the Mayo Foundation as a fellow in obstetrics and gynecology in 1934. She became a member of the clinic staff in 1938.

* * *

Dr. S. A. Slater, superintendent of the Southwestern Minnesota Sanitorium, located near Worthington, was a guest at a meeting of the Jackson Kiwanis Club on March 6.

* * *

Major Jules O. Meyer, a former Grand Rapids physician, is in Europe and is stationed with the 546th Medical Clearing Company in Frankfurt, Germany, as chief of professional services, it was announced on March 30. Dr. Meyer was graduated from the University of Minnesota in 1938.

* * *

Guest speaker at a meeting of the junior-senior high school Parent-Teachers Association in Stillwater on April 18 was **Dr. Albert V. Stoesser,** Minneapolis. Dr. Stoesser discussed physical development of teen-agers and requirements for normal growth.

WELCOME!

We desire to extend welcome to the delegates and members of the Minnesota State Medical Association at its Annual Convention to be held in Duluth, June 12, 13 and 14.

We trust that your Convention will be a most successful one and that you will enjoy your visit to Duluth.

Dr. William L. Benedict, of the section on ophthalmology at the Mayo Clinic, has been named a consultant and member of the advisory committee of the National Society for the Prevention of Blindness.

* * *

The principal speakers at a medical seminar held in Mankato on March 14 were **Dr. Arnold J. Kremen,** assistant professor of surgery at the University of Minnesota, and **Dr. Forrest H. Adams,** assistant professor of pediatrics at the University. The meeting was the second of a series of eight being conducted in Mankato for physicians of the area. The title of Dr. Kremen's address was "Cancer of the Gastrointestinal Tract," and Dr. Adams' subject was "Rheumatic Fever."

* * *

Dr. Joseph E. McCoy, Thief River Falls, celebrated his eightieth birthday in February. A graduate of the University of Louisville, Kentucky, in 1897, Dr. McCoy has practiced medicine for fifty-three years. Lately he has been devoting his attention mainly to the manufacture and distribution of a compound for treating ulcers.

* * *

Members of the **Oliver Clinic** in Graceville were busy attending various meetings during the early part of March. Dr. I. L. Oliver attended the annual meeting of the Chicago Surgical Sosiety in Chicago. Dr. N. W. Wagner spent a few days at the University of Minnesota's Center for Continuation Study, participating in a course of pediatrics. Dr. G. L. Barnett attended the county medical society officers' meeting in Saint Paul. Dr. Barnett had previously advanced from vice president to president of the West Central Minnesota Medical Society, upon the resignation of Dr. Wayne Rydhag of Brooten, who had moved to Minneapolis.

* * *

On April 1, **Dr. Robert Estrem** returned to his post at the Estrem Clinic in Fergus Falls. He had been on leave of absence from the clinic for three and one-half years while studying surgery at the University of Minnesota and Minneapolis Veterans Hospital. Back at the Estrem Clinic he is limiting his practice to surgery.

* * *

Dr. Ralph Rossen, state commissioner of mental health, gave a talk at a meeting of members, husbands and friends of the University of Minnesota Faculty Women's Club in the Coffman Memorial Union on March 16. A motion picture on mental health, entitled "Let There Be Light," was also presented.

* * *

The marriage of Miss Constance M. Otten and **Dr. Jack V. Wallinga** took place in St. John's Lutheran Church at Twin Lakes on March 18. Dr. Wallinga, son of the late Dr. John H. Wallinga of Saint Paul, is a graduate of the University of Minnesota Medical School and is now studying under a fellowship in psychiatry at the University.

Dr. Richard M. Magraw, who quit private practice three years ago to study psychiatry, recently had an article published in the Bulletin of the University of Minnesota Hospitals and Minnesota Medical Foundation. In the article, which was entitled "Psychological Medicine in a General Medical Setting," Dr. Magraw pointed out that the use of psychiatric medicine, or the "human approach," does not require more time than the average practitioner has to spare, and that this "comprehensive approach" makes possible quicker, and in many cases more accurate, diagnosis and treatment.

A graduate of the University of Minnesota Medical School in 1943, Dr. Magraw completed a year of surgical training and then practiced medicine at Two Harbors for two and one-half years. He recently completed a three-year fellowship in psychiatry at the University Hospitals.

* * *

Dr. Arthur H. Wells, Duluth, president of the Minnesota division of the American Cancer Society, discussed recent developments in cancer research at a school for cancer work volunteers in Pine City on March 29.

* * *

Dr. L. G. Smith, Montevideo, announced on March 28 that **Dr. R. E. Risch** of Minneapolis would soon become associated in practice with him and with Dr. M. A. Burns and Dr. Floyd Burns. Dr. Risch, it was stated, would move to Montevideo as soon as he could dispose of his practice in Minneapolis, where he has practiced medicine since his graduation from the University of Minnesota Medical School.

* * *

It was announced on April 11 that **Dr. Henry B. Blumberg,** formerly of Saint Paul, would open offices the following week in Fairmont for the practice of medicine. A graduate of Northwestern University Medical School, Dr. Blumberg joined the Army in 1942 and served both in the South Pacific area and in Europe. Later he spent three years at the Boston City Hospital and the Pratt Diagnostic Center. He then returned to Saint Paul and became affiliated with the Earl Clinic. He has taken postgraduate work at the University of Minnesota.

* * *

Dr. Adrian R. Jensen, Crookston, attended a meeting of the state poliomyelitis planning committee in Minneapolis on March 31. He was appointed a member of the committee by the State Board of Health.

* * *

Three Saint Paul physicians were guest speakers at a meeting of the Saint Paul Surgical Society on March 15. Dr. Abbott Skinner presented a paper on "Perforated Peptic Ulcer." Dr. E. M. Jones discussed the same topic. Dr. Wallace H. Cole spoke on "Intermedullary Fixation of Fractures."

geons at Winnipeg on April 3 and 4 were three Mayo Clinic staff members: Dr. Joseph M. James, r. Virgil S. Counseller and Dr. Paul R. Lipscomb. r. James spoke on arterial lesions of the extremties; Dr. Counseller conducted a panel discussion on esarian section and uterine prolapse; Dr. Lipscomb poke on stenosing tenosynovitis at the radial styloid rocess and was moderator at a panel discussion on urgery of the hand.

* * *

Dr. Ralph Papermaster, Two Harbors, supervised cancer detection clinic held in Two Harbors on March 18. The clinic was for all of Lake County, which is said to have one of the highest cancer death ates in Minnesota. Fifteen physicians and seventyive volunteer workers helped to conduct the clinic.

* * *

On March 1, **Dr. Reynold A. Jensen,** associate professor of psychiatry and pediatrics at the University of Minnesota, discussed psychosomatic medicine when he spoke at the sixth of a series of medical seminars held in St. Cloud.

* * *

"The Value of Relaxation" was the title of a talk given by **Dr. C. M. Jessico,** Duluth, at the annual meeting of the Duluth Health Council on March 20. The meeting was open to the public.

* * *

The quarterly meeting of the Consultation Committee of the **Minnesota Trudeau Society** was held at Sunnyrest Sanatorium, Crookston, on March 25. Cases from Sunnyrest Sanatorium and from Oakland Park Sanatorium at Thief River Falls were reviewed by the committee.

Members of the committee are Dr. Ejvind Fenger, of Glen Lake Sanatorium, Minneapolis, chairman; Dr. William D. Seybold, Mayo Clinic, Rochester; Dr. S. T. Sandell, of Nopeming Sanatorium, Duluth; Dr. M. M. Williams, of the Minnesota State Sanatorium, Walker; Dr. George C. Roth, of Saint Paul; Dr. H. Falk, of Minneapolis Veterans Hospital, and Dr. R. R. Hendrickson, superintendent of Sunnyrest Sanatorium, Crookston.

* * *

Dr. John Stam, of the Worthington Clinic, discussed the development of eating habits of the pre-school child at a meeting in Brewster on March 28. The meeting was the second of a series for mothers of children of pre-school age.

* * *

Two Minneapolis physicians will present reports at the Sixth International Congress of Pediatrics in Zurich, Switzerland, July 24 to 28. Dr. John M. Adams, associate professor of pediatrics at the University of Minnesota, will discuss the relationship of the common cold in adults to pneumonia in babies. Dr. Leonard A. Titrud will describe the surgical treatment of certain types of epilepsy.

Minnesota Cancer Detection Center.—Physical abnormalities requiring medical attention were found in more than one-half of the 3,265 examinations conducted in the University of Minnesota's Cancer Detection Center during the first two years of its operation.

Cancer was detected in thirty-four persons—fifteen men and nineteen women. Thirty cases of cancer were diagnosed on the first visit, while four were discovered during a second examination, one year after the first. In the 1,732 examinations (53 per cent) which revealed conditions requiring medical attention, examining physicians found, in addition to cancer, 776 pre-cancerous conditions, 564 benign tumors, and 2,149 instances of other abnormal conditions, non-cancerous but calling for immediate treatment. Most common of the pre-cancerous conditions were rectal polyps, which accounted for 369 of the 776 instances of pre-cancerous lesions.

Of the 3,265 examinations conducted at the center in its first two years, 2,226 were initial examinations and 1,039 were annual check-ups. Slightly more than half of the persons examined were women.

Dr. David State, director of the center, announced at the time the two-year report was released, "Results of our first two years of operation have been better than we anticipated. Apart from the fact that we were able to detect thirty-four cancers, we were able to catch most of them extremely early, and, accordingly, treatment of these tumors was more successful than the average. Without discounting the importance of detecting these cancers, we feel that it was of much more practical value that we found such a large number of pre-cancerous lesions, which are relatively simple to treat."

The cancer detection center is open to Minnesota men and women aged forty-five or over, who are unaware of any cancer symptoms in themselves. Admission is by appointment only, and more than 21,000 applications for appointments have already been received.

* * *

Dr. Mario Fischer, Duluth, St. Louis County health officer, was named a member of a temporary committee to handle preparation of the new St. Louis County infirmary at Virginia. The committee was appointed to function until a county agency could be named to assume charge.

* * *

It was announced on March 30 that **Dr. J. T. Boswell** would move to Wanamingo in July and open offices for the practice of medicine. A graduate of the University of Ohio, Dr. Boswell at the time of the announcement was serving his internship at the U. S. Naval Hospital at Great Lakes, Illinois. Wanamingo has been without the services of a resident physician since last August when Dr. C. N. Rudie moved to St. Peter to become a staff member of the state hospital there.

Two Saint Paul physicians were speakers at a public meeting in St. Cloud on March 13. **Dr. John F. Briggs,** president of the Minnesota Heart Association, spoke on "Your Heart," and **Dr. Paul C. Benton,** in-

An Observation on the Accuracy of Digitalis Doses

Withering made this penetrating observation in is classic monograph on digitalis: "The more I aw of the great powers of this plant, the more it eemed necessary to bring the doses of it to the greatest possible accuracy."[1]

To achieve the greatest accuracy in dosage and at the same time to preserve the full activity of the leaf, the total cardioactive principles must be isolated from the plant in pure crystalline form so that doses can be based on the actual weight of the active constituents. This is, in fact, the method by which Digilanid® is made.

Digilanid contains all the *initial* glycosides from Digitalis lanata in crystalline form. It thus truly represents "the great powers of the plant" and brings "the doses of it to the greatest possible accuracy".

Clinical investigation has proved that Digilanid is "an effective cardioactive preparation, which has the advantages of purity, stability and accuracy as to dosage and therapeutic effect."[2]

Average dose for initiating treatment: 2 to 4 tablets of Digilanid daily until the desired therapeutic level is reached.
Average maintenance dose: 1 tablet daily.
Also available: Drops, Ampuls and Suppositories.

1. *Withering, W.:* An account of the Foxglove, London, 1785.
2. *Rimmerman, A. B.:* Digilanid and the Therapy of Congestive Heart Disease, Am. J. M. Sc. *209:* 33-41 (Jan.) 1945.

The first of eight **weekly medical seminars** was held i Austin on March 15. Twenty-five physicians from he surrounding area attended the meeting, at which he principal speakers were Dr. George N. Aagaard nd Dr. Richard L. Varco, of the University of Minne- ota.

* * *

One of the speakers at a session of the Duluth and rrowhead Health Day on April 14 was **Dr. Earl E. arrett,** Duluth, who spoke on the topic "The Doc- or."

* * *

Dr. and Mrs. H. O. McPheeters, Minneapolis, spent he month of March vacationing in the West Indies and enezuela. Much of the time was used in visiting hos- itals and medical centers.

* * *

Plans for the establishment of a **rehabilitation linic** in Saint Paul for patients released from mental ospitals were announced by Dr. Ralph Rossen, state ommissioner of mental health, at a joint meeting on arch 14 of the Saint Paul Area Public Health Coun- il and the Ramsey County Citizen's Mental Health Com- ittee. The clinic, he said, would be like the one re- ently set up in Minneapolis. Counselors would help patients get suitable employment, handle difficult relations with employers, check patients' progress and help to prevent the need for readmission to an institution. Said Dr. Rossen, "It is hoped that with careful follow-up programs operated by such clinics, patients could be released from institutions sooner, and consequently more patients could be handled."

* * *

Dr. Christopher Graham, Rochester, celebrated his ninety-fourth birthday anniversary on April 3.

* * *

Announcement was made on March 23 that **Dr. Roberta G. Rice** of Minneapolis would assist Dr. George Friedell in his practice at Ivanhoe while Dr. Friedell was recovering from injuries sustained in an automobile accident.

* * *

An Upper Midwest industrial health conference was held on May 10 in Minneapolis under the joint sponsorship of the Minneapolis Chamber of Commerce and the Hennepin County Medical Society. General chairman of the event was **Dr. Leonard S. Arling,** Minneapolis.

* * *

The newly constructed **Mork Clinic** in Anoka opened its doors to the public on March 27. Construction work was begun last August. The two-story building houses the offices of Dr. Frank E. Mork and Dr. A. Harold Mork, and contains examining rooms, treat-

ment rooms, laboratories, x-ray room, business office and a reception room. The clinic has been furnished almost entirely with new equipment.

Also housed in the building are two additional office suites, one of which is occupied by a dentist and the other, on Mondays and Thursdays, by Dr. Donald T. Cundy of Minneapolis, an ophthalmologist.

* * *

A recent addition to the staff of the Willmar State Hospital is **Dr. Kenneth W. Douglas,** formerly of St. Peter, who began his duties at the hospital late in March.

* * *

A new program of protection against **radiation hazards** was started at the University of Minnesota on April 5, when all faculty members working with radioactive materials met to discuss methods of avoiding injury caused by radiation. The protective program, which utilizes four different types of instruments for detecting radioactivity, was developed by a committee headed by Dr. Wallace D. Armstrong, head of physiological chemistry at the University. At the meeting the detection instruments were demonstrated and an eight-page pamphlet prepared by the committee was given to the faculty members.

* * *

Community co-operation has provided Oklee with its first resident physician in more than five years. About two years ago the people of Oklee, a community of 500-plus population, started a campaign to persuade a physician to come to the town. Learning that physicians would be interested if modern working facilities were available, the people formed an organization and began planning the construction of a modern, well-equipped medical clinic.

The result is a $34,000 structure with quarters for a medical office, a dental office and an ambulance garage. The one-story building, of modern design, was opened for public inspection on March 16.

Now occupying the medical office is Dr. F. L. Behling, who moved to Oklee from Moorhead. As for the rest of the building, the Oklee organization is looking for a resident dentist for the town and is hoping that an ambulance for the garage can be acquired soon.

* * *

Dr. Paul M. Smith, Lake Crystal, and his wife and two sons narrowly escaped injury on March 30 when their car was struck on the highway by a heavy truck. The collision ripped off the left side of Dr. Smith's car but injured no one. The truck driver was charged by police with careless driving.

* * *

The American Cancer Society's new motion picture, **"Breast Cancer: The Problem of Early Diagnosis,"** was shown to members of the medical profession in Minneapolis on March 16 and in Saint Paul on March 17. Dr. Robert A. Huseby, William A. O'Brien professor at the University of Minnesota, presented a talk after the showing in Minneapolis. Dr. J. M. Culligan, Saint Paul, introduced the motion picture at the Saint Paul showing.

The film, second in a series of teaching films sponsored by the American Cancer Society and the National Cancer Institute of the U. S. Public Health Service, is now available for showing throughout the state. It can be secured by contacting the Minnesota Division of the American Cancer Society at 622 Commerce Building, Saint Paul.

The new motion picture emphasizes the steps necessary for early diagnosis of breast cancer. Normal breast development, the early signs of cancer, and the complete technique for breast examination are shown in detail.

HOSPITAL NEWS

Louis E. Weiner Memorial Hospital, Marshall.—At a meeting held in the new Louis E. Weiner Memorial Hospital in Marshall on March 27, the physicians of Marshall adopted by-laws, rules and regulations to form the medical staff of the hospital. In an election, Dr. W. W. Yaeger was elected president; Dr. B. C. Ford, vice president, and Dr. K. A. Peterson, secretary.

It was announced that physicians living outside of Marshall would be accepted on the courtesy staff of the hospital through application to the administrator and would be accorded the same privileges of the hospital as the active staff members.

* * *

Fairview Hospital, Minneapolis.—Dr. Silas C. Anderson was elected chief-of-staff at the annual meeting of the medical staff of Fairview Hospital in March. Other new officers include Dr. Myron Lysne, vice chief-of-staff; Dr. Louis J. Roberts, secretary, and Dr. Glenn L. Peterson, treasurer. New members of the executive committee are Dr. J. C. Giere, Dr. R. T. Soderlind, Dr. John Moe, and Dr. D. B. Frane.

* * *

Charles T. Miller Hospital, Saint Paul.—Ground was broken for the six-story addition to the Charles T. Miller Hospital on March 6. The addition is expected to be completed in about eighteen months. It will provide new operating rooms, x-ray and physical therapy departments and an additional 125 beds.

BLUE CROSS—BLUE SHIELD

Both Blue Cross and Blue Shield subscribers used more benefits in February than in January this year. Doctors submitted 747 more claims in February for services to Blue Shield subscribers, and received $34,973 more in Blue Shield payments compared with January. Hospitals reported fewer Blue Cross cases in February, but provided more days of hospital care and received $57,349 more in Blue Cross payments for services to Blue Cross subscribers. Altogether, Blue Shield benefits in February totalled $132,242 and Blue Cross benefits in February totalled $798,441. Blue Shield benefits during the first two months of 1950 amounted to $229,511.62, an increase of 95 per cent over the $117,811.76 paid to doctors during the first two months of 1949.

Of the total 3,322 Blue Shield claims submitted in February, 2,569 were for surgical, medical and obstetrical care given subscribers in hospitals, 737 for care

given subscribers in doctors' offices, and sixteen for care given subscribers in homes. Participating Blue Shield doctors submitted 3,172 of the total claims, and non-participating doctors submitted 150 claims, of which seventy-one claims were from doctors practicing outside the state of Minnesota.

Surgical cases accounted for 1,971 or 59 per cent of the total claims in February, medical cases for 1,016 or 31 per cent of the total claims, and obstetrical cases for 291 or 10 per cent of the total claims in February. The payment of claims in February were made for services rendered to 230 subscribers prior to November 1, 1949 to 336 subscribers in November, to 713 subscribers in December, to 1,577 subscribers in January and to thirty-one subscribers in February.

One reason for delays in payment is the increasing number of claims presented by medical doctors listing surgery performed but giving no indication that another doctor actually performed the surgery. The Blue Shield payment is naturally paid to the doctor submitting the original claim. When at some later time the surgeon's claim is presented, the Blue Shield office must request a refund from the first doctor paid, since the Blue Shield contract requires that payment be made to the doctor performing the surgery. This problem is called to the attention of the doctors in Minnesota so that these unintentional errors may be avoided and Blue Shield payments can be accurate and prompt.

A report from the Blue Cross Commission, co-ordinating agency for the ninety Blue Cross plans in the United States and Canada, indicated that hospitalization benefits to Blue Cross subscribers during 1949 drew a larger share of the Blue Cross plans yearly income than ever before.

Total income for all Blue Cross plans in 1949 was $388,193,814. Of this amount, hospitals received $327,857,819 or 84.46 per cent for service to Blue Cross members—an increase of almost $57,000,000 over the amount paid hospitals during 1948.

During January and February, 1949, Minnesota Blue Cross payments to hospitals totalled $1,327,287. This year, hospitalization benefits for the first two months totalled $1,529,534.

Enrollment in Minnesota Blue Cross totalled 989,591 as of February 28, 1950, and Blue Shield enrollment totalled 292,455.

BOOK REVIEWS

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical Libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

ULTIPLE SCLEROSIS AND THE DEMYELINATING DISEASES. Proceedings of the Association for Research in Nervous and Mental Diseases, December 10 an 11, 1948. 675 pages. Illus. Price $12.00, cloth. Baltimore: Williams & Wilkins Co., 1950.

ARVEY CUSHING—Surgeon, Author, Artist. Elizabeth H. Thomson. Foreword by John F. Fulton. 347 pages. Illus. Price $4.00, cloth. New York: Henry Schuman, 1950.

OME CONTEMPORARY THINKING ABOUT THE EXCEPTIONAL CHILD. Proceedings of a Special Conference on Education and the Exceptional Child of the Child Research Clinic of the Woods Schools. 64 pages. Langhorne, Pa.: The Woods Schools, 1949.

AW-GE-MAH (Medicine Man). Louis J. Gariepy, M.D. 326 pages. Price $3.00, cloth. St. Paul, Minnesota: Northland Press, 1950.

AY'S MANUAL OF THE DISEASES OF THE EYE FOR STUDENTS AND GENERAL PRACTITIONERS. Revised and edited by Charles A. Perera, M.D., Assistant Clinical Professor, College of Physicians and Surgeons, Columbia University, New York; Associate Attending Ophthalmologist, Presbyterian Hospital, New York. 512 Pages. Illus. $5.00. 20th ed. Baltimore: Williams & Wilkins Co., 1949.

The popularity of this text is attested by the fact nat this is the twentieth edition (the first having apeared in 1900). A total of 378 illustrations, including nirty-two plates with ninety-three colored figures, makes nis the most widely illustrated small work on ophthalnology that has come to my attention. Many of the ntiquated illustrations have been replaced with exellent new ones. The colored plates constitute a valuable tlas of the external diseases of the eye, of the affections f the anterior segment, and of the changes in the ocular undus.

The new and revised material includes the treatment f conjunctivitis, the classification and therapy of disases of the optic nerve, the use of the newer antibiotics, he surgical correction of oculomotor anomalies and the cular manifestation of systemic diseases.

The large amount of material included within the overs of this manual is amazing. It is small wonder hat this text his remained for years the standard manal on diseases of the eye for students and general pracitioners.

Harold J. Rothschild, M.D.

UINIDINE IN DISORDERS OF THE HEART. By Harry Gold, M.D., Professor of Clinical Pharmacology at Cornell University Medical College, Attending-in-Charge of the Cardiovascular Research Unit at the Bethel Israel Hospital, Attending Cardiologist at the Hospital for Joint Diseases, Managing Editor of the Cornell Conferences on Therapy. 115 pages. Price, $2.00. New York: Paul B. Hoeber, Inc., 1950.

"Quinidine in Disorders of the Heart" is a concise, eadable little manual of 100 pages by a physician with vide experience both in pharmacology and clinical nedicine. Indications, dosage, toxic reactions are well resented, and the various arrhythmias are capably lescribed. Case histories enliven the discussion. However, those of us who use Quinidine to prevent or lelay the onset of permanent auricular fibrillation and

BEN SOMMERS, M.D.

ESSENTIALS OF OBSTETRICAL AND GYNECOLOGY PATHOLOGY. By Robert L. Faulkner, M.D., F.A.C.S., Assistant Professor of Gynecology, The Western Reserve Medical School; Associate Gynecologist, University Hospitals of Cleveland, Ohio, and Marion Douglass, M.D., formerly Assistant Professor of Gynecology, The Western Reserve Medical School. 2d ed. 357 p. Illus. Price $8.75. St. Louis: The C. V. Mosby Co., 1949.

It was a privilege and I derived a great amount of pleasurable reading in reviewing this book. The wealth of fundamental knowledge contained in such a book is invaluable to anyone, and it certainly helped me in my thinking and understanding of the basic problems in obstetrical and gynecological pathology.

The book is well organized and each chapter is devoted to the specific structure being discussed. The first chapter explains the proper methods of obtaining and processing surgical specimens and biopsies so as to facilitate the rendering of a more accurate diagnosis by the pathologist which in turn will aid the gynecologist to a more concise understanding of the problem which confronts him. Succeeding chapters describe the histology, physiology and pathology pertinent to the female anatomy in this order: vulva, vagina, cervix, endometrium, myometrium, fallopian tube, ovary and the pathology relative to pregnancy.

In order to understand more fully the pathological physiology involved each chapter is preceded by a brief, concise, discourse of the physiology, histology and embryology involved, which gives one the basic facts stripped of non-essentials and eliminates dull reading material. There are many illustrations of macroscopic and miscroscopic pathologic specimens interspaced throughout the chapters, plus several color plates.

To criticize the book adversely, I feel that the authors should have included a bibliography. Very often, when investigating a particular problem, valuable leads are obtained from a book such as this which may assist an investigator to find further information utilizing the various indices. Surely, the bibliography which Drs. Faulkner and Douglass possess and incorporated into their text would make the book of inestimable value. I also believe that a chapter on the pathology and pathological physiology of the toxemias of pregnanc should be included and the material organized in th same style as the other chapters in the book.

This text can be highly recommended as a hand reference to anyone interested in gynecological an obstetrical pathology bearing in mind that the book i primarily concerned with the essentials of this subjec matter. For anyone preparing for board examination the book should be a time saver in reviewing basic knowledge in this speciality.

J. F. MELANCON, M.D.

UROLOGICAL SURGERY. By Austin Ingram Dodson, M.D F.A.C.S., Professor of Urology, Medical College of Virginia Urologist to the Hospital Division, Medical College of Vi ginia; Urologist to Crippled Children's Hospital; Urologist t St. Elizabeth's Hospital; Urologist to St. Luke's Hospital an McQuire Clinic. 2d ed. 855 pages. Illus. Price $13.5 St. Louis: C. V. Mosby Co., 1950.

This revised edition is probably the best single reference for open urological procedures. It is not intende as a textbook of urology, although surgical anatomy an basic principles of diagnosis and treatment are reviewe briefly. No attempt is made to cover the field of endoscopic urology. There is an excellent concise chapter o endocrinology as related to the prostate.

Although a number of valuable operative procedure are necessarily omitted, Dr. Dodson's book is a highl useful reference for both the postgraduate student i urology and for those practitioners who do open uro surgery.

MURRAY P. ERSFELD, M.D

REVIEWS OF MEDICAL MOTION PICTURE

The Committee on Medical Motion Pictures of th American Medical Association has completed the secon revised edition of the booklet entitled "Reviews o Medical Motion Pictures." This booklet now contain 225 reviews of medical and health films reviewed i *The Journal AMA* to January 1, 1950. Each film ha been indexed according to subject matter. The purpos of these reviews is to provide a brief description an an evaluation of motion pictures which are available t the medical profession. Each film is reviewed by competent authorities and every effort has been made t publish frank, unbiased comments. Copies are availabl at a cost of 25 cents each from: Order Department American Medical Association, 535 North Dearborn Street, Chicago, 10, Illinois.

PABENA
½ LB. NET (227 GM.)
PABENA
PRECOOKED OATMEAL
vitamin-and-mineral-enriched
Pabena consists of oatmeal, malt syrup, powdered beef bone specially prepared for human use, sodium chloride, powdered yeast, and reduced iron. Pabena furnishes vitamin B complex, including thiamine, and nutritionally important minerals (iron, copper, calcium, and phosphorus). As a result of thorough cooking and drying, Pabena is easily digested. It is palatable, convenient to prepare, economical to use.
REQUIRES NO COOKING • Add milk or water, hot or cold. Serve with milk or cream.
MEAD JOHNSON & CO.
EVANSVILLE, IND., U.S.A.
precooked oatmeal
companion to Pablum

Growing in favor with physicians

Pabena* is *oatmeal*... and has the rich, full oatmeal flavor.

Like PABLUM,* PABENA is enriched with important vitamins and minerals and is thoroughly cooked and dried.

In addition, PABENA is valuable for infants and children who are sensitive to wheat. It is an ideal first solid food.

PABENA and PABLUM provide variety of cereal flavor that is welcomed by both mother and child.

PABENA and PABLUM, like all Mead's products, are not advertised in lay publications.

Q. S.

This prescription abbreviation for "a sufficient quantity" provides us, we believe, with an opportunity to point out how the widespread availability of Lilly products works to your advantage.

Any pharmacy to which your prescription may go is conveniently near one of the many wholesale distributors carrying a complete assortment of Lilly preparations. A Lilly specification, therefore, is a demand which can be readily executed without disappointment. Your chosen course of treatment may thus be faithfully followed without delay.

Resistant Bacterial Infections

AUREOMYCIN HYDROCHLORIDE LEDERLE

Aureomycin is now widely used for the treatment of infections that have proven resistant to other chemotherapeutic agents, or combinations of such agents. Aureomycin does not commonly provoke resistance in bacteria, and its ability to penetrate cell membranes and diffuse through the body fluids assures the presence of the therapeutic material everywhere it is needed.

Aureomycin has been found effective for the control of the following infections: African tick-bite fever, acute amebiasis, bacterial and virus-like infections of the eye, bacteroides septicemia, boutonneuse fever, acute brucellosis, gonorrhea resistant to penicillin, Gram-positive infections (including those caused by streptococci, staphylococci, and pneumococci), Gram-negative infections (including those caused by the coli-aerogenes group), granuloma inguinale, *H. influenzae* infections, lymphogranuloma venereum, peritonitis, primary atypical pneumonia, psittacosis (parrot fever), Q fever, rickettsialpox, Rocky Mountain spotted fever, subacute bacterial endocarditis resistant to penicillin, tularemia and typhus.

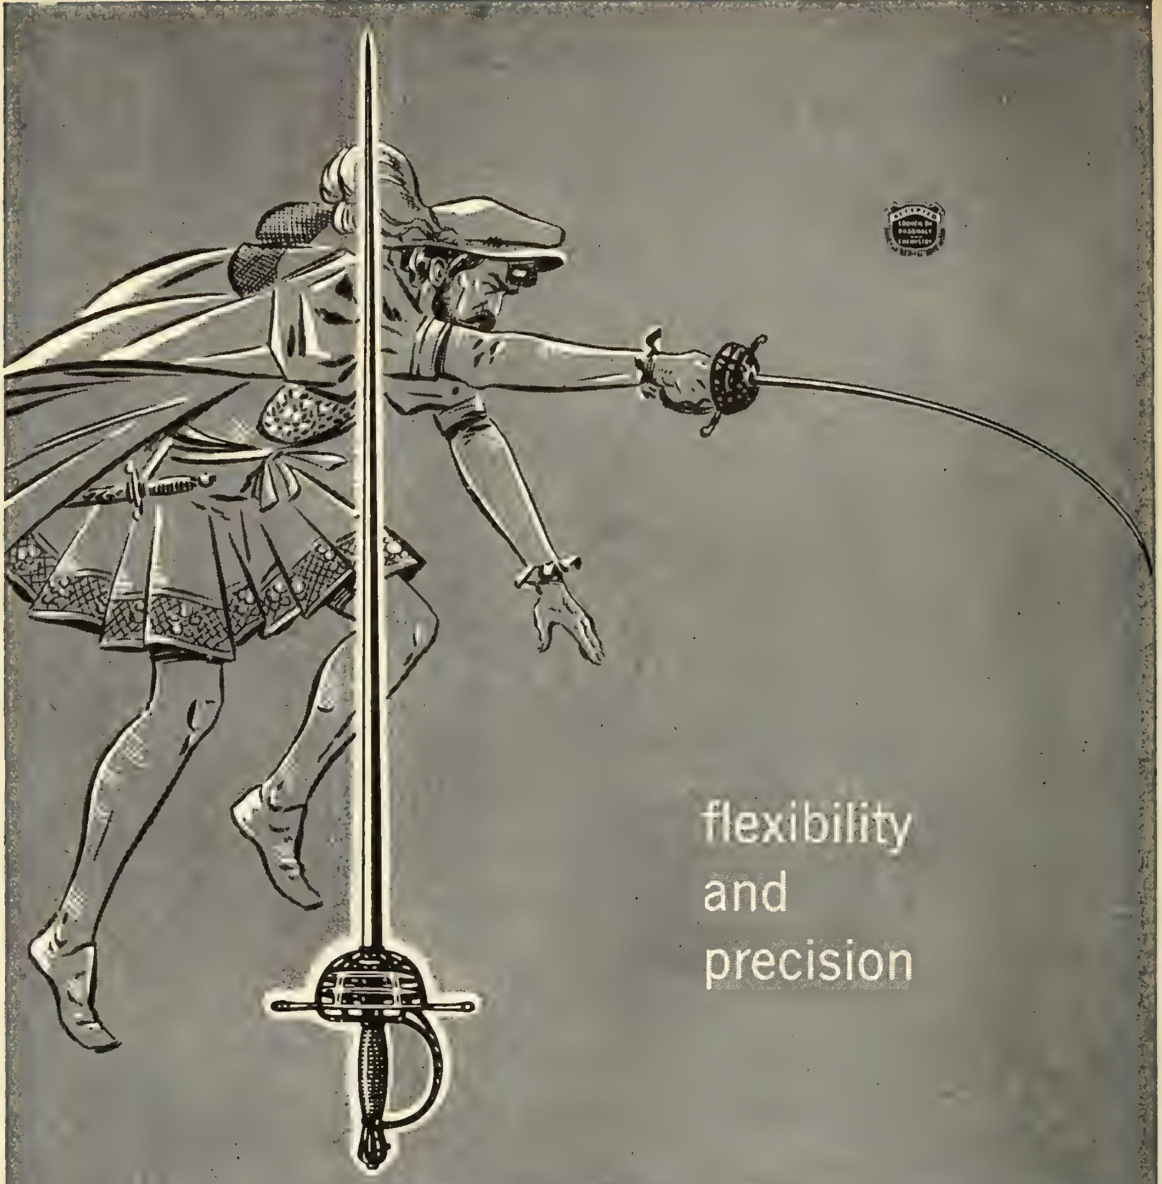
Ophthalmic: Vials of 25 mg. with dropper; solution prepared by adding 5 cc. of distilled water.



PURODIGIN®
in
Cardiac
Therapy
. . .

PURODIGIN is available in three strengths: Tablets of 0.1 mg., 0.15 mg., and 0.2 mg. This facilitates closer adjustment of maintenance dosage to the patient's requirements . . . minimizes need to "stagger" larger and smaller doses or to prescribe irregular intervals between doses.

For reliable, efficient cardiotherapy, specify **PURODIGIN**—pure crystalline digitoxin, Wyeth.

Wyeth® WYETH INCORPORATED • PHILADELPHIA 3, PA.

A POSITIVE MEANS OF

Promoting Nutritional Adequacy

Whenever the need for dietary supplementation arises—as in anorexia, perverted food habits, during and following illness, and in gastrointestinal disease—the regular use of Ovaltine in milk can be of signal value. Taken daily, this well-rounded multiple dietary supplement gives virtual assurance of nutritional adequacy.

As indicated in the table, Ovaltine in milk provides virtually all essential nutrients in balanced, generous amounts. Its protein is biologically complete. It supplies not only B complex vitamins, but also vitamins A and D as well as ascorbic acid and essential minerals.

The delightful taste and easy digestibility of this food beverage is relished by patients, hence the recommended three glassfuls daily are taken without resistance.

THE WANDER COMPANY, 360 N. MICHIGAN AVE., CHICAGO 1, ILL.

OVALTINE
OVALTINE

Ovaltine

Three servings of Ovaltine, each made of ½ oz. of Ovaltine and 8 oz. of whole milk, provide:*

PROTEIN	32 Gm.	VITAMIN A	3000 I.U.
FAT	32 Gm.	VITAMIN B_1	1.16 mg.
CARBOHYDRATE	65 Gm.	RIBOFLAVIN	2.0 mg.
CALCIUM	1.12 Gm.	NIACIN	6.8 mg.
PHOSPHORUS	0.94 Gm.	VITAMIN C	30.0 mg.
IRON	12 mg.	VITAMIN D	417 I.U.
COPPER	0.5 mg.	CALORIES	676

*Based on average reported values for milk.

Two kinds, Plain and Chocolate Flavored. Serving for serving, they are virtually identical in nutritional content.

"In general, symptomatic improvement [of menopausal symptoms] was striking within 7 to 14 days after treatment..." with "Premarin."

Gray, L.: J. Clin. Endocrinol. 3:92 (Feb.) 1943.

Many clinicians have found that "Premarin" therapy usually brings about prompt relief of distressing menopausal symptoms. Furthermore, symptomatic improvement is followed by a gratifying sense of well-being in a majority of cases. This is the "plus" in "Premarin" therapy which tends to quickly restore the patient's normal mental outlook.

Four potencies of "Premarin" permit flexibility of dosage: 2.5 mg., 1.25 mg., 0.625 mg., and 0.3 mg. tablets; also in liquid form, 0.625 mg. in each 4 cc. (1 teaspoonful).

While sodium estrone sulfate is the principal estrogen in "Premarin," other equine estrogens...estradiol, equilin, equilenin, hippulin...are probably also present in varying amounts as water-soluble conjugates.

Ayerst ®

. . . . YES! *Keleket's* new
Give you COMPLETE

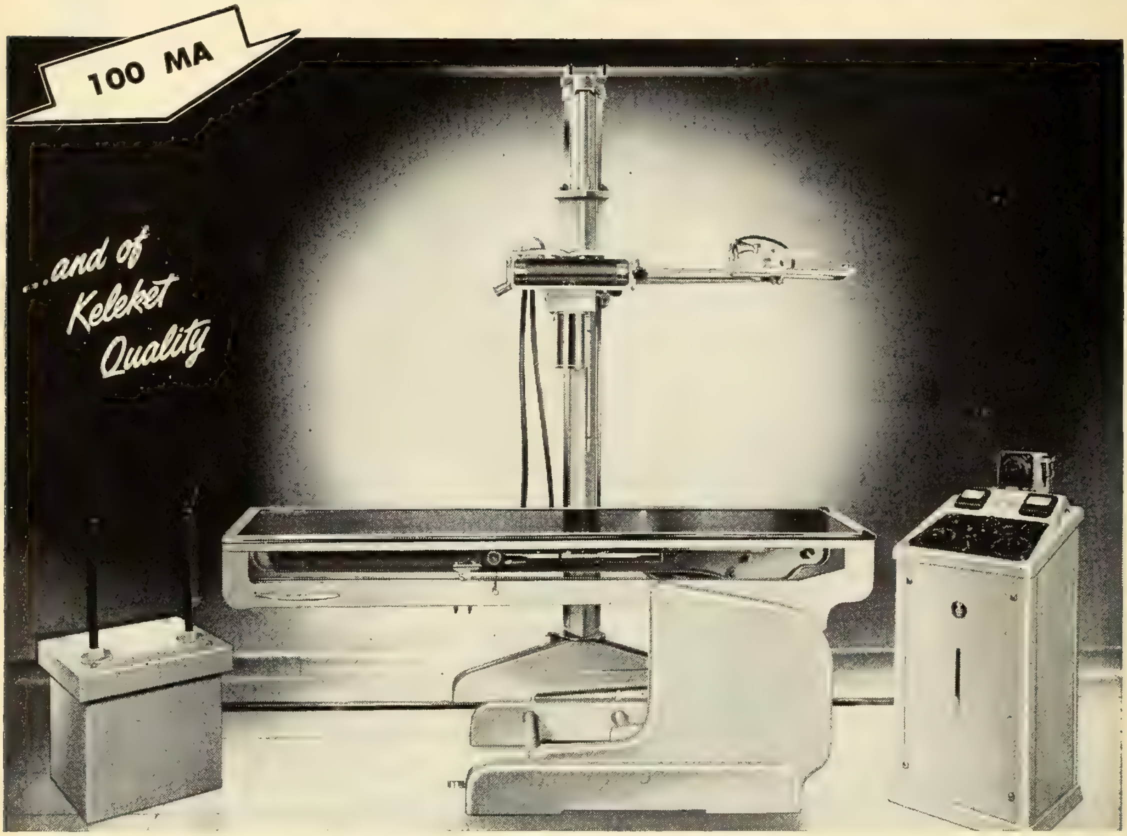

Illustration above shows 100 MA Combination with the basic table and Floor-To-Ceiling tubestand. This combination includes the famous Keleket Multicron Generator.

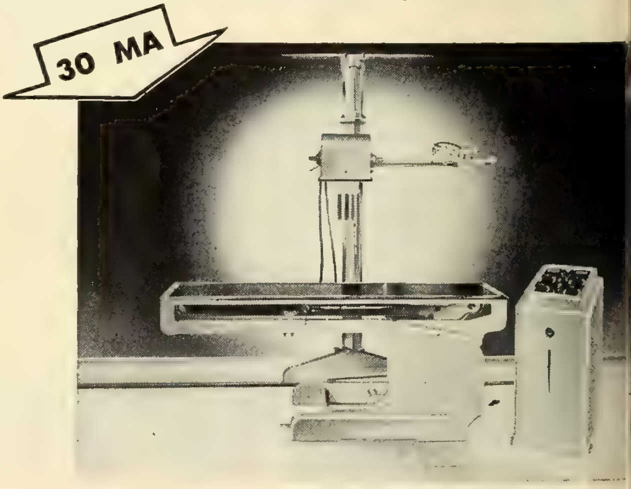
Here is how the Keleket Add-A-Unit Combinations Work

Choose the combination to suit your practice!

You purchase the new standard (not a reduced) size Keleket Tilt Table and Tubestand. Then add either 15, 30 or 100 MA tube and generating equipment. You can advance from 15 to 30 and to 100 MA but still retain the original table and tubestand. As a result, this investment is never lost when you step up to higher power tubes and generating equipment.

Illustration below shows 30 MA combination with the same basic table and Floor-To-Ceiling tubestand. This combination includes the 30 MA self-contained tubehead and precision control.



Add-a-Unit Combinations
X-RAY EQUIPMENT
. for FULL RANGE Fluoroscopy and Radiography

leket scores again, with a new approach to the use and rchase of X-ray equipment. Keleket has developed a JLL SIZE Standard Tilting Table with a completely w, highly flexible floor to ceiling tubestand. This basic ray equipment is equally adaptable for either 15, 30 100 MA tube and generating units.

IOWS WITH YOUR REQUIREMENTS

art out with the simplest 15 MA tubehead; then at a ture date change to a 30 MA tubehead, if you desire. henever you're ready, step up to a 100 MA generating it. As a result, your Keleket equipment grows with ur requirements.

HROUGHOUT ALL INTERCHANGES YOU RE-AIN THE SAME KELEKET "ADAP"-TABLE AND JBESTAND.

TURE COSTS SAVED

is means you eliminate one of the biggest cost factors in equipment—new table and tubestand costs as you step up your tube capacity and power.

In addition, your original investment is never lost—Keleket offers you generous allowance values on the equipment you interchange.

FULL RADIOGRAPHIC-FLUOROSCOPIC FACILITIES

Any of these combinations will fully meet your current needs for full range radiography and fluoroscopy. Perform radiography in horizontal and trendelenburg positions, vertical and horizontal fluoroscopy. The tubestand, for example, is so flexible that you can swing the tubehead away from the table and radiograph stretcher cases on the opposite side.

And if you want a bucky diaphragm, even the lowest cost unit is equipped to accommodate one.

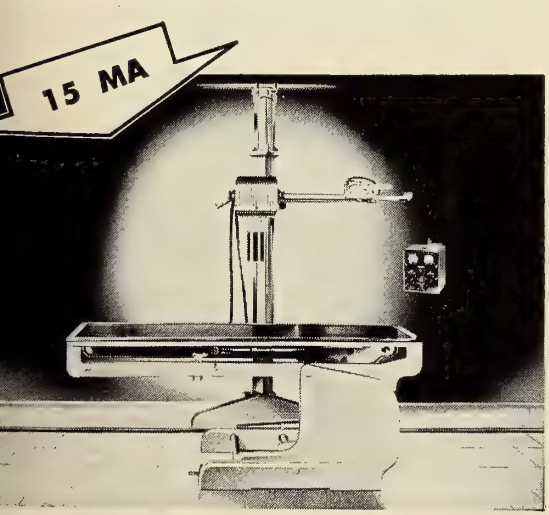
Write or phone for more information

Keleket X-Ray Sales Corporation of Minnesota

1225 Nicollet Avenue Minneapolis 3, Minnesota

A new approach to use and purchase of X-Ray equipment.

ustration below shows same basic table and tubestand with new self-contained 15 MA tubehead and control.



GENEROUS ALLOWANCE VALUES... YOUR ORIGINAL INVESTMENT NEVER LOST.

Yes, with minimum cost you can obtain full radiographic-fluoroscopic facilities with Keleket Add-A-Unit Combinations—made possible for the first time with the new Keleket Flexible Floor-To-Ceiling Tubestand and Basic Tilt Table. Write for complete information.

WHEN OBESITY IS A PROBLEM

Clinicians have long noted that the forward bulk of the heavy abdomen with its fat-laden wall moves the center of gravity forward. As the patient tries to balance the load, the lumbar and cervical curves of the spine are increased, the head is carried forward and the shoulders become rounded. Often there is associated visceroptosis. Camp Supports have a long history among clinicians for their efficacy in supporting the pendulous abdomen. The highly specialized designs and the unique Camp system of controlled adjustment help steady the pelvis and hold the viscera upward and backward. There is no constriction of the abdomen, and effective support is given to the spine. Physicians may rely on the Camp-trained fitter for precise execution of all instructions.

If you do not have a copy of the Camp "Reference Book for Physicians and Surgeons", it will be sent on request.

hether the sneeze is seasonal or perennial

TRIMETON® offers more patients greater symptomatic relief. In *severe* hay fever TRIMETON was found to be the most effective antihistamine among six drugs tested, affording relief to 75 per cent of patients.[1] In *mild* hay fever, benefit is obtained by 90 per cent of patients.

In perennial allergic rhinitis, "TRIMETON . . . is distinctly superior . . . and . . . was strikingly effective. . . . The figure of 85 per cent satisfactorily treated patients is impressive."[2]

TRIMETON®

(brand of prophenpyridamine)

TRIMETON, a potent, well tolerated antihistamine is also indicated for symptomatic control of urticaria, angioedema, atopic eczema and dermatitis, antibiotic sensitivity reactions and some cases of asthma.

TRIMETON is available in 25 mg. scored tablets. Bottles of 100 and 1000.

PROVIDES PROTECTION WITHOUT IRRITATION

Evidence obtained by direct-color photography shows that the cervix remains occluded for as long as ten hours after an application of "RAMSES"* Vaginal Jelly.

"RAMSES" Vaginal Jelly immobilizes sperm in the fastest time recognized under the authoritative Brown and Gamble method of measuring the spermatocidal power of vaginal jellies or creams. This has been established by repeated tests for spermatocidal activity conducted by an accredited independent laboratory.

Clinical observation of patients receiving daily applications of "RAMSES" Vaginal Jelly for three-week periods reveals no evidence of irritation or other untoward effect.

"RAMSES" Vaginal Jelly is acceptable to even the most fastidious patient because it provides efficient protection without leakage or excessive lubrication. It is available at all pharmacies in regular and large tubes; the regular tube is also available in a package containing a measured applicator.

ACTIVE INGREDIENTS: Dodecaethyleneglycol Monolaurate 5%, Boric Acid 1%, Alcohol 5%.

THROAT SPECIALISTS REPORT
ON 30-DAY TEST OF CAMEL SMOKERS:

"Not one single case of throat irritation due to smoking Camels!"

Yes, these were the findings of throat specialists after a total of 2,470 weekly examinations of the throats of hundreds of men and women who smoked Camels—and only Camels—for 30 consecutive days.

IT WAS GOOD TO HAVE THE DOCTOR'S WORD ON IT, BUT I KNEW CAMEL MILDNESS AGREED WITH MY THROAT FROM THE START. THEY'RE A GREAT SMOKE!

ACCORDING TO A NATIONWIDE SURVEY:

MORE DOCTORS SMOKE CAMELS

THAN ANY OTHER CIGARETTE

Yes, doctors smoke for pleasure, too! In a nationwide survey, three independent research organizations asked 113,597 doctors what cigarette they smoked. The brand named most was Camel.

PHOSPHO-SODA (FLEET)®

A LAXATIVE FOR *judicious* THERAPY

because **of its**

Broad Clinical Acceptance

Phospho-Soda (Fleet)'s* wide acceptance by physicians everywhere is a tribute to its prompt, gentle laxative action—thorough, but free from disturbing side effects. Leading modern clinicians attest its safety and dependability as a pre-eminent saline eliminant for judicious relief of constipation. Liberal office samples on request.

*Phospho-Soda (Fleet) is a solution containing in each 100 cc. sodium biphosphate 48 Gm. and sodium phosphate 18 Gm. Both 'Phospho-Soda' and 'Fleet' are registered trade marks of C. B. Fleet Company, Inc.

When She's Tempted

by Forbidden Foods

So she weakens—she goes on an ice cream bender. Will she return to the prescribed course of calorie-counting, or will this be the turning point when many physicians prescribe Desoxyn Hydrochloride? There's good reason for prescribing Desoxyn—a little goes a long way. Small daily doses decrease the craving for food, increase the energy output and impart a feeling of well-being which encourages dietary adherence.

Smaller dosage is possible because weight for weight Desoxyn is more potent than other sympathomimetic amines. One 2.5-mg. tablet before breakfast and another about an hour before lunch is usually sufficient. A third tablet may be taken in midafternoon if necessary, and if it does not cause insomnia. Investigators have shown, too, that Desoxyn has a faster action, longer effect and relatively few side-effects. With judicious use Desoxyn is safe, simple and effective. Why not give it a trial? On it may lean the continued cooperation of a sweet-famished obese patient.

ADVANTAGES AND LIMITATIONS OF THE QUANTITATIVE VDRL SLIDE TEST

ANNE C. KIMBALL, Ph.D., and HENRY BAUER, Ph.D.

Minneapolis, Minnesota

STARTING July 1, 1950, it is planned that blood specimens giving positive VDRL serological slide tests for syphilis will be reported quantitatively. This test has been studied in the Minnesota Department of Health Medical Laboratories since October 1, 1949. The following summary of results is presented as an indication of the value and limitations of this added test procedure.

TABLE I. CORRELATION OF KOLMER-WASSERMANN WITH QUANTITATIVE VDRL SLIDE TEST RESULTS ON 3227 SPECIMENS

VDRL Test		Kolmer-Wassermann Test Result						Total VDRL Tests Positive/Dilution	
		Negative	Doubtful ± or 1+	Positive 2+	Positive 3+	Positive 4+	Anticomplementary	No.	%

Technique of the Test

The VDRL slide test for syphilis was originally published by the Venereal Disease Research Laboratories of the United States Public Health Service, Staten Island, in 1946[1], after the isolation of cardiolipin from beef heart was published by Pangborn[3] in 1941. The antigen emulsion is prepared with buffered saline and an alcoholic solution of 0.03 per cent cardiolipin and 0.9 per cent cholesterol and sufficient lecithin to give "standard" sensitivity. Basically this antigen is similar to other lipodal antigens used prior to this time. The major advantage is in its reproducibility.

The qualitative tests are performed using 0.05 c.c. undiluted serum and 1 drop (60 drops per 1 c.c.) of antigen emulsion, and the results are read and reported as negative, weakly positive or positive. The quantitative test is done on all specimens giving a positive qualitative test on undiluted serum. Serial twofold dilutions of each specimen are prepared with saline and each one is tested in the same manner as in testing undiluted serum. The highest dilution giving a positive reaction is reported as follows:

From the Minnesota Department of Health, Section of Medical Laboratories.

The authors are indebted to H. G. Irvine, M.D., Acting Director of the Division of Venereal Diseases, Section of Preventable Diseases, for helpful suggestions in preparing this paper.

	Dilution						Report
Spec. No.	1:2	1:4	1:8	1:16	1:32	1:64	
103	W.P.*	Neg	Neg	Neg	Neg	Neg	Positive Undiluted Only
176	Pos	Pos	Pos	Pos	Pos	W.P.*	Positive Diluted 1:32
572	Pos	Pos	W.P.*	W.P.*	Neg	Neg	Positive Diluted 1:4

*Weakly Positive.

The major advantage of such quantitation is that it measures the strength of positivity into a much higher range than the usual gradation of 1+ through 4+ on testing only undiluted serum. For example, in the above table specimens No. 176 and 572 would both have been read positive 4+ by the older gradation method, but the quantitative tests show specimen 176 to be eight times more positive than specimen 572.

During the six-month period October, 1949, through March, 1950, 3227 specimens giving a positive result on undiluted serum with the VDRL slide test have been quantitated. Approximately 200 additional specimens gave positive VDRL slide tests, but there was insufficient serum to perform the quantitative test. We mention this group only to emphasize the importance of submitting a full vial of blood.

In the last two columns of Table I the number and percentage of specimens giving a positive result in the various dilutions is shown. Sixteen hundred and forty-two or 51 per cent of the specimens are positive only undiluted or in dilution 1:2. We can expect to find a considerable number of false positives in this group although many of these are specimens from treated cases of syphilis. No statement can be made in regard to exact specificity since clinical data is not available. The correlation of quantitative results with the Kolmer-Wassermann test results is also shown on Table I. In 993 of these 1642 specimens the Kolmer-Wassermann test also shows some reaction.

In 915 specimens, or 28 per cent, the VDRL tests are positive in dilutions 1:4 and 1:8. False positives will be unusual in this group. The Kolmer test shows some reaction in 785 of these 915 specimens.

In 670 specimens, or 21 per cent, the VDRL is positive in dilutions 1:16 or higher. False positives in this group will be exceedingly rare.

Weakly positive and negative VDRL slide tests are not shown in Table I since the quantitation procedure is not applicable to this group. Such specimens may show a reaction in the Kolmer test.

TABLE II. QUANTITATIVE VDRL SLIDE TESTS

Results on retesting 100 positive specimens.

	Tests done the same day	Second tests done 1 or 2 days later
Exact agreement	71	59
Second test one dilution higher	13	16
Second test one dilution lower	16	21
Second test two dilutions higher	0	1
Second test two dilutions lower	0	3

TABLE III. QUANTITATIVE VDRL SLIDE TESTS

Results on pairs of specimens from 210 individuals collected within one week.

	No.	%
Exact agreement	113	53.8
Second specimen 1 dilution higher	33	15.7
Second specimen 1 dilution lower	54	25.7
Second specimen 2 dilutions higher	7	3.3
Second specimen 2 dilutions lower	2	1.0
Second specimen 3 dilutions higher	1*	0.5

*Early case of syphilis—see text.

Retesting Specimens

Table II is a summary of results on retesting 100 positive specimens the same day, and one or two days later. As shown in the first column, when these specimens were retested the same day there was exact agreement in 71 per cent. Disagreement greater than one dilution was not encountered. Variables which contribute to the 29 per cent disagreement in results are as follows:

1. Variation in reading by two technicians.
2. Deviations from ideal mixing. (It is not practical to use separate pipettes for each dilution.)
3. Variation in serologic pipettes.
4. Variation in time elapsed since inactivation of the serum.

As shown in the second column of Table II, when the retesting was done one or two days later only 59 per cent gave exact agreement, 37 per cent differed by one dilution, and 4 per cent gave results differing by two dilutions. For this group additional variables contributing to disagreement are as follows:

TABLE IV. CORRELATION OF QUANTITATIVE KAHN AND QUANTITATIVE VDRL TESTS ON 628 SPECIMENS

Standard Kahn Result	Serum Dil.	Quanti-tative Kahn Units	VDRL Test Results											Total No.
			Neg.	W.P.	Pos. Undil. Only	Positive in Dilutions

*Median Titre (see text)

1. Slight variation in the antigen emulsion prepared on different days.
2. Effect of reinactivation on the specimens.

Study of Second Specimens

From 210 individuals we have received two specimens collected within one week. Within seven days we would seldom expect to see significant changes in titre of positivity except in progressing primary syphilis. An analysis of the agreement and disagreement of quantitative tests on these pairs of specimens from 210 individuals is presented in Table III. Exact agreement was obtained in 53.8 per cent. The percentage of specimens showing disagreement to the extent of one dilution or two dilutions is very similar to the results obtained with testing the same specimen on different days, as shown in Table II. From this we conclude that differences of one dilution on two specimens cannot be considered to indicate any significant change in titre of positivity, and in a small percentage of cases even two dilutions may be due to technical variations. In only one pair of specimens was there disagreement in excess of two dilutions. These specimens were from a case of primary syphilis (see Case D, Table VI). The first specimen was positive in dilution 1:8, the second, collected seven days later, was positive in dilution 1:64. A third specimen, received from this individual four months later, gave negative VDRL and Kolmer-Wassermann test results.

Comparison with the Quantitative Kahn

Quantitative Kahn tests and quantitative VDRL slide tests have been done on 628 specimens. In Table IV the number of specimens giving each grade of quantitative Kahn test result is shown, as well as the dilutions positive by the quantitative VDRL slide test. The median titre for the quantitative VDRL test is starred for each type of quantitative Kahn reaction except the five highest titres. Too few specimens fall into these groups to permit designating a median titre. The quantitative VDRL tests gave the median titre indicated or varied only one dilution in 91 per cent of the specimens. Only five specimens varied by more than two dilutions from the median titres indicated. Three of these five specimens were from the same individual and gave quantitative Kahn titres of 20 units, 10 units, and 2 units, respectively. The VDRL, Kolmer-Wassermann, and Hinton tests were all negative on these three specimens. This individual is not a reported case of syphilis, and these are probably false positive Kahns.

Table IV clearly indicates the greater sensitivity of the VDRL test as compared with the Kahn. The dilutions used for the quantitative Kahn are given to bring out this difference. For example, forty-five specimens gave quantitative Kahns of 40 units. These Kahn tests are positive in a serum dilution of 1:10. When these forty-five specimens were tested by the quantitative VDRL test, fourteen were positive in dilution 1:16, eighteen positive in dilution 1:32, twelve in dilution 1:64, and one in dilution 1:128. With the 153 specimens giving negative Kahn tests the VDRL test results were negative in seventy-six, weakly positive in forty, positive "undiluted only" in twenty-nine, positive diluted 1:2 in seven, and positive diluted 1:4 in one.

Taking into consideration the technical varia-

TABLE V. CORRELATION OF SPINAL FLUID TEST RESULTS WITH QUANTITATIVE VDRL SLIDE TEST RESULTS ON BLOODS FROM 168 KNOWN CASES OF SYPHILIS

Kolmer negative, VDRL test positive on 7 specimens.
Kolmer positive, insufficient material for VDRL test on 10 specimens.

tions in test procedure in these two methods of quantitation, the correlation of the results is good. Quantitation by both procedures adds little, if any, significant information.*

Spinal Fluid Test Results Compared with VDRL Blood Test Results

Both spinal fluid and blood specimens have been tested on 168 known cases of syphilis. These results are presented in Table V classified into three groups according to the results on the spinal fluids: (1) Kolmer and VDRL tests both positive; (2) Kolmer or VDRL test positive; and (3) Kolmer and VDRL tests both negative. The quantitative VDRL tests on the blood serum show an equally wide range of titre in all three groups. In group 1 with both tests positive on the spinal fluid, 24 per cent of the blood specimens are positive diluted only 1:2 or show even weaker results. In group 2 with one test positive on the spinal fluid, 32 per cent of the bloods are positive diluted 1:2 or weaker.

Colloidal gold curves have also been done on the majority of these specimens. In group 1 the gold curves were positive on forty-one specimens (thirty-six gave "paretic" type curves) and negative on twenty. Nine positive colloidal gold curves were on spinals from the fifteen persons with low titre (1:2 or less) quantitative tests in the blood. In group 2, positive gold curves were obtained on ten spinal fluids (eight gave "paretic" type curves) and fifteen were negative. Four of the positive gold curves were on spinals from the thirteen persons with low titre (1:2 or less) quantitative tests in the blood. One specimen in group 1 and one in group 2 was insufficient for the gold curve. In the negative group (3) one positive gold curve was obtained; forty-eight gave negative gold curves. This test was not done on the thirty-one remaining specimens.†

The important point brought out by the data in Table V is that, if the blood serum shows only a low titre positivity, this is no assurance that the spinal fluid will be negative, nor is a high titre suggestive that the spinal fluid will be positive. Consequently the quantitation of positivity in blood serum is of no value in predicting the reaction in spinal fluids. Whenever indicated, spinal fluid should be examined regardless of the results on the blood.

Illustrative Cases

In Table VI are given the serologic findings on a few selected individuals. Additional data on these patients follow.

(A) This individual is not syphilitic. The diagnosis was infectious mononucleosis, which frequently gives false positive tests for syphilis. The heterophile antibody titre was positive in dilution 1:640 on the first blood specimen tabulated.

(B) This is not a case of syphilis. The individual was vaccinated for smallpox "shortly" before the collection of the first blood specimen. Several times each year we see false positives following smallpox vaccination, which on occasion show stronger positivity than Case B.

(C) Primary syphilis. Penicillin treatment given in the interval between the two blood specimens.

(D) Primary syphilis. Penicillin, neoarsphenamine, and bismuth administered between the second and third specimens.

---

*Quantitative Kahn tests have been done on special request in these laboratories. The quantitative Kahn test is to be discontinued after September 30, 1950. Both quantitative Kahns and VDRL slide tests will be done when the quantitative Kahn is requested during the transition period, July, August, and September, 1950, providing the volume of serum is sufficient. Two full vials will be necessary for the battery of tests (VDRL, Kolmer, Kahn, Hinton, and quantitative Kahn and VDRL).

†The colloidal gold test is done only on request and on those spinal fluid specimens showing a positive serological test for syphilis.

*Spinal Fluid.

(E) Secondary syphilis. Source of infection to Case C above. Penicillin treatment given in the interval between the second and third specimens.

(F) Early latent syphilis. First specimen collected five days prior to delivery of infant. Syphilis diagnosed and treated two months prior to delivery.

(F′) Infant of Case F. One month old when first blood was submitted. According to our records, no treatment was administered to the infant, and the case has not been reported.

(G) Early latent syphilis was diagnosed in 1943. Irregular and inadequate treatment for several years. Adequate treatment regime in 1947 and 1948, completed nine months prior to the first specimen tabulated. Spinal fluid negative in 1947. No change in positivity in the seven-month period covered. This patient's blood will probably not become negative.

(H) Cardiovascular syphilis. Diagnosed and treated six years ago. Spinal fluid examination requested but not done at that time. Positive spinal fluid collected two days after the third blood specimen tabulated.

(I) Originally reported as secondary syphilis. Adequately treated with penicillin, arsenic and bismuth for eight months. Attending physician evaluates the later change as a relapse.

Discussion

Requesting repeat specimens (two full vials) on all diagnostic problems will be continued. The results on the Kahn and Hinton tests, in addition to the VDRL and Kolmer, will frequently aid in diagnosis or exclusion of syphilis. (See patients A and D in Table VI.)

There is no evidence establishing that the height of titre of any quantitative tests for syphilis correlates directly with clinical activity. The value of the quantitation is that the higher the titre is, the stronger the serological evidence is for supporting a diagnosis. In addition, the change in titre can be noted during treatment which can, on occasion, give an earlier warning of relapse than would be possible with qualitative tests.

Referring to Table I, the greater incidence of anticomplementary Kolmer test results in very high titred specimens is apparent. It is well established that anticomplementary reactions occur frequently in specimens giving very high titred quantitative tests and in contaminated specimens. Also, blood serum from some individuals is anticomplementary because of unknown factors. Because bacterially contaminated specimens are associated with anticomplementary reactions, the quality of any anticomplementary specimen may be questioned. As a result, the two basic recommendations (1) that all positive blood tests be repeated before diagnosis and (2) that bloods be collected with sterile technique, both become even more important when considering an anticomplementary result.

When an anticomplementary result is reported and when serological results are for any reason questionable, it will frequently be necessary to submit several specimens over a period of months, and a spinal fluid, before a sound conclusion can be reached as to diagnosis or exclusion of syphilis.

As is readily understandable, we have no clinical data on a large percentage of patients in this study. We hope that none the less the data here presented will prove valuable. Quantitative VDRL tests have been reported to Dr. F. W. Lynch, Saint Paul, and he is presenting his evaluation of the procedure in this issue.[2]

Summary

Starting July 1, 1950, it is planned to report all positive VRDL slide test results quantitatively. Quantitation has the following advantages:

1. The higher the dilution in which the test is positive, the less is the possibility of a false positive.
2. Changes in titre can be followed during treatment. This is most important in early syphilis.

Limitations:

1. Regardless of the quantitation, all positive tests should be repeated. Two full vials of blood for the "battery of tests" are desirable on second specimens.
2. Variations of one dilution (first specimen positive diluted 1:4, second specimen positive diluted 1:8) have no significance, since such change can be due to several technical variations in the test procedure.
3. Strength of positivity as indicated by the dilution does not correlate with the clinical activity of the infection.
4. Spinal fluid examination should be made whenever indicated, regardless of the quantitative result, since over 25 per cent of patients with positive spinal fluids have low titre positive reactions in the blood (positive diluted 1:2 or weaker.)
5. Approximately 6 per cent of our specimens have been insufficient for quantitation. One full vial (6.0-7.0 c.c.) is requested.

The quantitative Kahn test (done only on special request) will be discontinued on October 1, 1950.

FALL IN TUBERCULOSIS DEATH RATE

The annual death rate from tuberculosis dropped 10 per cent in 1948 to 30.0 per 100,000 population, Federal Security Administrator Oscar R. Ewing said today. He cited an article, "Tuberculosis Mortality in the U. S. 1948," which appears in the current Tuberculosis Control Issue of *Public Health Reports*, published by the Public Health Service, Federal Security Agency.

The decline in the tuberculosis mortality rate, the article points out, has accelerated during the postwar years. The rate dropped 5 per cent from 1945 to 1946, and 7 per cent from 1946 to 1947.

The tuberculosis death rate for the population as a whole has been steadily declining for the past twenty years, so that the 1948 rate was less than half the 1930 rate, according to the article. The decline is sharper in some sections of the population than in others—sharpest of all in children under fifteen years of age. In persons over sixty-five years of age, on the other hand, the decline has been slow, and indeed in white males over sixty-five the tuberculosis death rate was higher in 1948 than in 1941.

In general, the article points out, the tuberculosis death rates for women have fallen more rapidly than those for men. The 1948 rate for females was about half of that for males. Mortality rates from this disease continue to be more than three times as high for the nonwhite groups as for the white, the article says.

The state with the lowest tuberculosis death rate in 1948 was Iowa with a rate of 9.5 per 100,000 population. The state with the highest rate, Arizona, dropped from 100 in 1947 to 82.4 in 1948.—*Public Health Service* Release April 12, 1950.

THE CLINICAL APPLICATION OF QUANTITATIVE REPORTS OF SEROLOGIC TESTS FOR SYPHILIS

FRANCIS W. LYNCH, M.D.
Saint Paul, Minnesota

SINCE the Serologic Laboratories of the Minnesota Department of Health will soon report quantitatively on reactions in serial dilutions of specimens tested with the VDRL antigen, this paper is presented in the hope of familiarizing Minnesota physicians with the expected advantages of such reports. Syphilis is not common in Minnesota but this fortunate fact does not lessen the need for offering these syphilitic patients the best possible care. The discussion is based on the results of studies on specimens submitted to the Minnesota Department of Health from private practice and from Ancker Hospital from October 1, 1949, to April 1, 1950, attempting to evaluate the limitation and advantages of such tests.* Capable clinicians may immediately ask whether these detailed reports may not encourage overdependence upon laboratory procedures and thereby diminish clinical acumen and effort. While this paper points out certain advantages to be gained from quantitative studies, the author wishes first to warn against too great dependence upon tests and his purpose is to assist in their cautious and correct application.

The most clearly evident limitations of quantitative tests are:

1. Quantitative studies do *not* eliminate the possibility of technical or clerical errors and one must not depend on results obtained on a single specimen.
2. Serial dilution of serum does not increase the *specificity* of a serologic reaction.
3. There is no *dependable* relation between the amount of reagin and severity of syphilis or the need for treatment.

Specificity

The VDRL antigen has increased the specificity of serologic tests for syphilis and quantitative reporting† will increase diagnostic accuracy in some cases since reactions occurring at higher dilutions are more likely to be specific than those observed only in undiluted serum. Just as before, in doubtful cases the VDRL report must be correlated with others since the likelihood of a false reaction is increased when there is conflict (e.g., VDRL negative, Kolmer positive, or the reverse). Variations in intensity of reaction may be reported in a series of tests at intervals of one or several weeks. While slight variations may be of no significance,‡ greater ones suggest lack of specificity, and sustained upward trends are likely to be significant of increasing specific activity. Since time to observe the serologic *trend* may be of great help in diagnosis, it is fortunate that in the absence of clinical evidence or spinal fluid changes, there seldom is need for haste. The addition of quantitative study does not change the general principles that through physical examination, accurate personal and familial history, spinal fluid study, and patience are necessary for the accurate diagnosis of syphilis.

> *"The interpretation of serologic tests for syphilis is of paramount importance in the diagnosis of syphilis and the follow-up of treated patients."*
> EVAN W. THOMAS *in*
> *"Syphilis, Its Course and Management."*

In this series diagnostic help from quantitation was obtained in several cases. Diagnosis had long been delayed in one case because of numerous variable and conflicting reports, but after several years a specimen was reported as 4-plus in all tests and VDRL positive in dilution of 1:8, and later at 1:16, the higher dilutions suggesting that the progressive serologic change had been great rather than slight in degree, as might have been suspected if the VDRL test had been reported only as positive.

In another instance a false diagnosis of syphilis may have been averted in the case of a penile lesion closely resembling a chancre. A series of tests was reported as follows:

Kline	2-plus	2-plus	4-plus
VDRL	pos.	pos. undiluted	pos. undiluted

Presented before the Minnesota Academy of Medicine, May 10, 1950, at St. Paul, Minnesota.

*This study was carried out with the generous co-operation of the Medical Laboratories of the Minnesota Department of Health, and consists of clinical observations relating to approximately 4 per cent of the positive serologic reactions studied in detail by Drs. Kimball and Bauer and reported in this issue of MINNESOTA MEDICINE.

†Details regarding the quantitative VDRL technic and method of reporting are discussed by Dr. Kimball.

‡Dr. Kimball's Tables II and III illustrate the variations to be expected in results on repeated testing of single specimens or on repeated specimens.

Too much importance was not placed upon the 4-plus report since the VDRL reaction occurred only in low titre. Only a few days later both tests reverted to negative. (Fortunately the Kolmer reaction had remained negative throughout the period of observation.)

In serial studies of several patients the VDRL reaction ranged from negative to positive in dilution of 1:2 in cases where other tests were reported negative to 4-plus, and no diagnosis of syphilis was made. Dr. Kimball's illustrative cases A and B further demonstrate these points.

Activity of Infection

Rising serologic titres must be appraised as possible evidence of early, untreated syphilis (acquired or congenital). Negative reactions occur during the first four or five weeks of infection, then follows a rather rapidly progressive rise in titre to a peak during the "secondary stage" of the disease, after which the serologic titre decreases and within a year or two becomes fairly stable, at levels which vary greatly from patient to patient and seem to have little or no relation to the severity of the disease. Though the serologic level is not directly related to the activity of the disease, negative serologic reactions are rare in *active* late syphilis. Clinical evidence of previously active inflammation may or may not be accompanied by serologic activity (e.g., cutaneous or osseous scars or inactive—"burned-out"—tabes with residual neurologic changes).

The following examples from this series show how undependable is the titre as an indicator of activity of infection and need for treatment:

Titre	*Nature of the Syphilis*
1:128	old, previously treated for cutaneous gumma.
1:64	old, previously treated slightly
1:64	old, untreated, cardiovascular syphilis.
1:32	late, active cutaneous syphilis.
1:16	late, active neurosyphilis.
1:8	late, persistent spinal fluid changes, recently re-treated.
1:2	late, treated, seroresistance in spinal fluid.
undil.	active interstitial keratitis.

Such examples clearly illustrate that quantitative reports must not be used as direct indications of the necessity for, or the character or amount of, treatment. The data presented by Dr. Kimball in Table 5 (and her Case H) clearly shows a lack of positive correlation between the degree and activity of neurosyphilis (as shown by spinal fluid changes) and the degree of reaction to the VDRL test.

Response to Treatment

The greatest advantage of quantitative serologic study is in the evaluation of results of modern, rapid, intensive therapy for early syphilis. Here one expects a rapid, progressive drop in titre to negativity in one to four months. (When treatment has been instituted before serologic reactions have become positive, or while they are still increasing in intensity, there may be a transitory rise immediately after starting to treat—a "serologic Herxheimer reaction"). Even when treatment has been started as early as one or two months after infection, one will observe some patients whose serologic response progresses steadily to a point just above negativity (e.g., weak positive, or positive undiluted only, or in dilution of 1:2) and then persists at that level, fluctuates slightly, or diminishes very slowly. Treatment has not failed; these patients have had adequate therapy and need not be re-treated. After treatment of early syphilis the blood should be tested monthly for a year, every two or three months the second year and semi-annually thereafter. The spinal fluid must be examined six to twelve months after completion of treatment, and abnormal changes require immediate therapeutic attention.

In this series a serologic Herxheimer reaction was noted in a patient with late congenital syphilis with doubtful serologic reactions, given penicillin therapy because of interstitial keratitis. Before treatment, on two occasions the Kolmer reaction was negative and the VDRL positive undiluted only, but following treatment the Kolmer reaction was doubtful 1 plus-minus and the VDRL positive when diluted 1:2.

In other instances the serologic reaction became less intense following treatment. A woman treated late in pregnancy gave birth to an infant who later developed evidence of osseous syphilis, and serologic reactions of Kline 4-plus, Kolmer 4-plus, VDRL positive in dilution of 1:2. Penicillin therapy was begun five weeks after birth and all the serologic reactions were completely negative three months later. Dr. Kimball's cases C.D. and E. illustrate similar response to treatment.

After rapid intensive treatment for early syphilis seroresistance at relatively high levels is rare (e.g., dilutions of 1:8 or greater). When there is no clinical evidence of active inflammation and the spinal fluid is normal, the significance of such seroresistance is questionable. Perhaps there may be small foci of slowly progressive infection or equally possibly the high level of antigen represents a favorable degree of immunity. At any rate there is little risk if such patients are re-treated after six months and then closely observed but given no therapy thereafter, unless the titre rises further.

The greatest benefit of quantitative tests is the early demonstration of serorelapse or re-infection (illustrated by Dr. Kimball's Case I). Serologically the two are indistinguishable. It must be emphasized that such setbacks are proved only when noted on two or more tests and never on a rise of serologic titre demonstrated on a single specimen. Clinically, the chancre of reinfection *precedes* the rise in titre while the mucocutaneous infectious relapse *follows* serorelapse. Frequently, it is important to distinguish the sequence and this can hardly be done without a series of tests with quantitative reports.

Early latent syphilis may respond less rapidly as in the patient whose reactions at start of therapy were Kline 4-plus, Kolmer 4-plus, VDRL positive 1:16 and were the same one month later. At four months the Kline and Kolmer remained 4-plus, but the VDRL was positive only in 1:8 dilution, offering evidence of some favorable effect from the treatment (See also Dr. Kimball's case F.)

In a patient with previously treated asymptomatic neurosyphilis the giving of penicillin failed to modify a VDRL positive reaction at 1:8 dilution. However, in clinically progressively active neurosyphilis similar treatment was followed by a change from VDRL positive at 1:16 to positive only when undiluted. (The Kolmer reaction remained 4-plus and the Kline changed from 4-plus to 3-plus).

Conclusions

Serologic study is increasingly important in syphilis, with quantitative reports offering certain advantages, which have been illustrated by examples selected from reports on a recently observed series of patients.

1. With reference to the recognition of false reactions, positivity in higher dilutions increases the likelihood that the reaction is specific.

2. Steadily rising titres may be demonstrated in early, acquired syphilis and in early, congenital syphilis (regardless of whether treatment was given the mother during pregnancy).

3. Transitory increase in titer may be found immediately after the institution of treatment (serologic Herxheimer reaction).

4. Falling titres are expected as a result of treatment, especially after modern intensive treatment for early syphilis. The most significant application of quantitative reports occurs in early syphilis with an initially favorable serologic response to treatment but later showing progressive increases in titre (serorelapse). Recognition of this serologic change allows institution of retreatment before clinical, infectious relapse exerts its disastrous influences on patient, family or other persons.

5. Quantitative reports are of considerably less significance in all other circumstances and the clinician must not base decisions on insignificant changes. It must be particularly remembered, for example, that positive in 1:64 dilution does not mean "twice as much syphilis" as in 1:32 dilution, but only that one more dilution of the serum allowed demonstration of a positive reaction which may have been due to technical error, extrinsic changes after collection of the serum, or normal and natural variation in the serum content of syphilitic reagin, without significance on the ultimate course of the disease.

6. It may be pertinent to point out a sequence not observed in this series. When gonorrhea and syphilis are acquired simultaneously, the former is often treated by penicillin before the latter is serologically or clinically demonstrable. The syphilitic infection may be aborted, masked or delayed in its appearance but frequently repeated serologic tests will aid in its early recognition and rising quantitative titers have obvious significance.

Health education and sanatorium treatment are our two greatest weapons in fighting tuberculosis. We must remember that each patient with active tuberculosis presents a medical problem, a social and welfare problem, an economic problem and, let us never forget, a public health problem.—R. D. Johnson, M.D., *Bull. Nat. Tuber. A.*, Jan., 1950.

PROGRESS IN MATERNAL AND INFANT HEALTH IN MINNESOTA

A Statistical Study of the Decade 1939-1949

A. B. ROSENFIELD, M.D., M.P.H.
Minneapolis, Minnesota
and
J. W. BROWER, M.A.
Saint Paul, Minnesota

Maternal Mortality

NATIONALLY, during the past decade the maternal mortality rate has dropped from 4 per 1,000 live births in 1939 to approximately 1 per 1,000 in 1949, a reduction of 75 per cent. In Minnesota the 1939 maternal mortality rate of 2.7 decreased to 0.7 per 1,000 live births in 1949, a similar reduction of 74 per cent. This period included the war years with their rising birth rates and reduced medical and nursing personnel. During the past five years, 1945-1949 inclusive, there was a reduction of 50 per cent, from 1.4 to 0.7 per 1,000 live births.

In 1947, at the peak of our birth rate (75,468 live births), Minnesota's mortality rate dropped to a new United States low of 0.6 per 1,000 live births. While we may well be proud of this accomplishment, which appears to have brought us to an almost irreducible minimum, it is apparent that a still greater reduction is possible when we consider that Oregon reduced its rate to a new national low of 0.4 per 1,000 live births in 1948.

The possibility of further reduction in maternal mortality is also indicated by a preliminary study of the recent EMIC program in Minnesota. During the four full years of the program, 1944-1947, a total of 18,457 live births occurred, with a maternal mortality rate of 0.7 per 1,000 live births. During this same period, 232,207 live births occurred in Minnesota outside the program, with a mortality rate of 1.1 per 1,000 live births, a very significant difference of 36 per cent. It should be noted, however, that the live births in the EMIC program constituted only 7 per cent of the total live births in the state during the four years mentioned. No data are available in our records as to parity of the mother. A preponderance of mothers were, however, in the safest age group of fifteen through twenty-nine years (88 per cent in contrast to the usual state proportion of only about 68 per cent), and the group was a more favored one economically, since medical and hospital care were provided for the asking. Nevertheless, the value of adequate and competent prenatal care, good obstetrical and postpartum care, hospitalization, consultation, and the use of blood and antibiotics, as well as public health programs, cannot be overlooked.

Because of the small number of maternal deaths in each county, there may be quite marked variations in rates from year to year. For this reason, maps were prepared for five-year periods. Map 1 includes all maternal deaths from 1935 through 1939, by counties. Map 2 includes deaths for 1945 through 1949. These maps show five years of recorded maternal deaths rather than the usual resident figures, in order to allocate deaths to the county of occurrence rather than the county where the prospective mother was given prenatal care. It is realized that this approach may influence rates adversely in some counties, but it may also indicate the areas where periodic study of their own maternal problems may be of value to communities in reducing preventable deaths. A comparison between maps 1 and 2 provides a graphic presentation of the improvement in maternal mortality during the period covered.

The state maternal death rate for the five-year period 1935-1939 was 3.5 per 1,000 live births. Twenty counties had rates less than 2.0; forty-three had rates between 2.0 and 4.0; twenty-four had rates over 4.0. Ten years later, in the five-year period of 1945-1949, rates were strikingly lower. The state maternal deaths rate was 0.85 per 1,000 live births. Eighty-one counties had rates less than 2.0; only five had rates between 2.0 and 3.9; only one county had a rate of 4.0 (5.3, to be exact).

The chief causes of maternal deaths are infection, toxemia, and hemorrhage. Table I shows the changes in percentage of deaths due to these causes during the ten-year interval under discussion.

In 1939, thirty-two (24 per cent) of the 136 maternal deaths were due to infection; twenty-six (19 per cent) to toxemia and a similar number to hemorrhage; and fifty-two (38 per cent) to other causes. In 1949, fifteen of the fifty-four maternal

Mr. Brower is Director, Division of Vital Statistics, Minnesota Department of Health.

deaths were due to infection (28 per cent), an increase of 4 per cent over the 1939 figures. Toxemia caused eleven deaths (20 per cent); hemorrhage was responsible for ten deaths (18.5 per cent); and eighteen (33 per cent) were due to other causes. From 1939 to 1949, there was a 74 per cent reduction in all causes; death from infection decreased 65 per cent; the other causes of maternal deaths decreased approximately 75 per cent.

The decrease in mortality for the three main causes of maternal deaths has undoubtedly been due to a number of interrelated factors. These include better obstetrical practice, more extensive and more adequate prenatal care, early transfusions, sulfonamides and antibiotics, increased hospitalization (more than 97 per cent in Minnesota), improved hospitalization facilities, and an increasing awareness by the public of the importance of adequate care, which has been promoted through public health education.

All others	18	52	2.3	10.3	–78

During the period from July 1, 1941 through June 30, 1942, the maternal mortality committee of the Minnesota State Medical Association in co-operation with the Minnesota Department of Health conducted an intensive study of the 112 maternal deaths that occurred in that period. In its report the committee pointed out the extent to which the physician was responsible for maternal deaths, as well as the importance of adequate prenatal care. It is felt that the study was a significant factor in the subsequent reduction of maternal mortality in this state. The Council of the Minnesota State Medical Association has approved a similar study by its maternal health committee for the year of 1950 in an effort to reduce maternal mortality still further.

The largest number of births occurred in the age groups twenty to twenty-four and twenty-five to twenty-nine. These made up 59 per cent of the total in 1939 and 61 per cent of the 1947 total (Table II). Risks in childbearing were low-

TABLE IV. TOTAL MINNESOTA AND INDIAN LIVE BIRTHS AND INFANT DEATHS

Minnesota, 1939 and 1949

Year	Live Births Minnesota No.	Live Births Indian No.	Infant Deaths Minnesota No.	Infant Deaths Minnesota Rate/1,000 l.b.	Indian No.	Indian Rate/1,000 l.b.
1939	50,228	537	1,798	35.8	22	41.4
1949	73,627	574	1,922	26.1	32	55.7

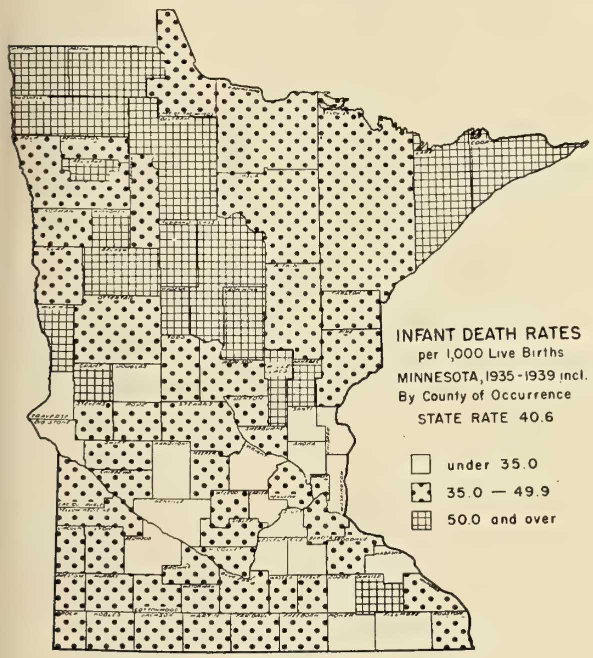
est in the age group twenty to twenty-four in 1939 with a mortality rate of 13.2 per 10,000 live births. For mothers fifteen to nineteen years old and twenty-five to twenty-nine years old the death rates were below those for all ages. Among mothers thirty years of age and over these rates increased in each succeeding age group, with a peak of 189.9 per 10,000 live births among mothers in the forty-five to forty-nine year group.

In 1947 the entire group of mothers aged fifteen to thirty-four years had a mortality rate of 4.7 or less, with a marked rise in the thirty-five to forty-four year group. The highest mortality occurred in the forty to forty-four year group (34.2 per 10,000). The lowest rate of 1.9 was in the fifteen to nineteen year age group. In the thirty to thirty-four year age group it was 2.1 per 10,000 live births. A comparison of maternal deaths in 1939 and 1947 shows that the greatest reduction took place in the fifteen to nineteen age group, where there was a decrease of 89 per cent. In the twenty-five to twenty-nine year age group the reduction was 82 per cent. A 66 per cent decrease occurred in the thirty to thirty-four year age group and a 64 per cent drop in the twenty to twenty-four year group. There was a 59 per cent decrease in the thirty-five to thirty-nine year group and a 57 per cent decrease in the forty to forty-four year group. No deaths occurred between forty-five and fifty years, although this group had the highest mortality rate in 1939. Interestingly enough, the safest childbearing age groups were fifteen to nineteen and thirty to thirty-four in 1947 instead of the usual twenty to twenty-four year age group.

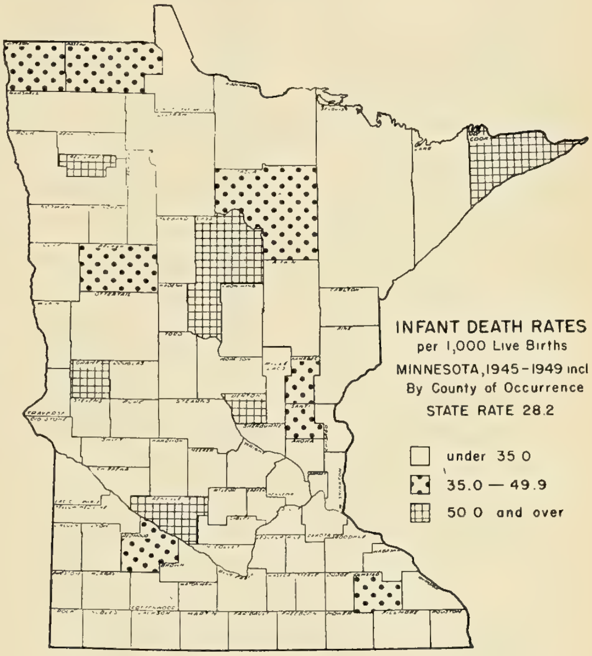
Infant Mortality

(Deaths Under One Year of Age)

In 1939, a total of 1,798 infants died before reaching their first birthday. In 1949, the number increased to 1,922. But this 7 per cent increase in deaths was accompanied by a 47 per cent increase in live births during the decade. The infant mortality rate, however, decreased from 35.8 to 26.1 per 1,000 live births—a reduction of 27 per cent (Table III). Incidentally, infant deaths (under one year of age) constitute from 70 to 75 per cent of all deaths under the age of fifteen in Minnesota. The number of stillbirths has remained about the same, but there has been a substantial reduction in the rate from 24.2 per 1,000 live births in 1939 to 16.4 in 1949, a 32 per cent decrease. The stillbirth rate has actually decreased 5 per cent more than the infant mortality rate.



Map 3.



Map 4.

A comparison of infant death rates by county of occurrence during 1935-1939 (Map 3) with the rates for 1945-1949 (Map 4) graphically illustrates the reduction in infant mortality during this decade. In the five-year period 1935-1939, the state rate was 40.6 per 1,000 live births. Nineteen counties had rates below thirty-five. Fifty-two had rates between thirty-five and fifty; sixteen had rates of fifty and over. Ten years later, during the period 1945-1949, the state rate decreased to 28.2. Seventy-three counties had rates less than thirty-five; eight counties had rates between thirty-five and 49.9; and only six had rates of fifty and over per 1,000 live births.

The non-white population in Minnesota constitutes less than 1 per cent of the total state population. There are approximately 14,000 Indians, constituting about 0.5 per cent of the population, a small number of Negroes, and comparatively few Mexicans, Chinese, and Japanese. The 1949 infant death rate among our Indians was more than twice as great as the overall state rate—55.7 in contrast with 26.1 per 1,000 live births (Table IV). The Indian rate increased more than one-third in 1949 over that of 1939. The high incidence of communicable disease among the Indians undoubtedly influences the infant death rate materially. Another factor is prematurity. While prematurity was the eighth leading cause of death in Minnesota in 1949, it was the sixth leading cause among the Indians.

It should be pointed out that the rates in the Indian group are less stable, since they are based on a relatively small number of mothers. Since the Indian population constitutes less than 0.5 per cent of the state population, such rates have no real significance and do not materially increase the state rate. There are, however, serious health problems in the Indian population.

The causes of infant deaths in 1939 and 1949 are shown in Table V. The four leading causes of death constituted over 75 per cent of all deaths during the first year of life in both 1949 and 1939. The leading cause was premature birth, which was responsible for more than one-third of all deaths in both 1949 (37.4 per cent) and 1939 (35.7 per cent). Congenital malformations were responsible for almost one-fifth of all deaths in infancy (19.4 per cent) in 1949, and one in every twelve deaths in 1939 (12.7 per cent). The third leading cause of death was birth injuries, and pneumonia and influenza were fourth.

The relative importance of the causes of death and the percentage of change during the past ten years is brought out more clearly when it is related to the number of live births. This is the

Minnesota, 1949 and 1939

Age at death	1949	1939	% Change
Under 1 day	37.1%	38.7%	—4
1 day to 1 week	28.7%	21.7%	+32
1 week to 1 month	9.1%	9.5%	—4
Under 1 month	74.9%	69.9%	+7
1 month to 1 year	25.1%	30.1%	—16

TABLE VIII. NEONATAL DEATHS FOR SELECTED CAUSES BY PERCENTAGE OF DISTRIBUTION
Minnesota, 1949 and 1939

	Deaths		Per Cent of Distribution	
	1949	1939	1949	1939
Total	1,440	1,258	100.0%	100.0%
Prematurity	707	625	49.1	49.7
Congenital malfor.	245	143	17.0	11.4
Birth injuries	242	257	16.8	20.4
Cong. debility and other diseases of early infancy	156	112	10.8	8.9
Pneumonia & influ.	40	46	2.8	3.6
Diarrhea & enteritis	15	8	1.0	0.6
External causes	14	16	1.0	1.3
Other causes	21	51	1.5	4.1

comparison of the death rate for selected causes per 1,000 live births. The 1939 death rate of 12.7 per 1,000 live births for premature births, the leading cause of death, decreased to 9.8, a reduction of 23 per cent. The rate for congenital malformation, the second leading cause, increased 11 per cent. It was the tenth leading cause of death in both 1948 and 1949. The relationship of German measles in the first trimester of pregnancy to the development of congenital malformations deserves serious consideration. A preliminary study of mortality in Minnesota due to congenital malformations, however, has shown no significant variation in relation to the incidence of German measles.

Deaths from injury at birth, the third leading cause, decreased 37 per cent. This fact would indicate better trained physicians and more competent obstetrical care. Pneumonia and influenza, the fourth leading cause of death, were responsible for 43 per cent fewer deaths. This reduction was due, no doubt, to the use of sulfonamides and antibiotics. Among other relatively less important causes of infant mortality, diarrhea and enteritis showed a reduction of 50 per cent, and deaths due to acute infectious diseases showed an even greater reduction of over 80 per cent. On the other hand, accidental deaths in this early age group increased 29 per cent in the past decade.

The greatest mortality occurs during the first thirty days of life—the so-called neonatal period—and this period shows the least reduction from 1939 to 1949. The infant mortality rate in that period decreased 27 per cent, the neonatal mortality decreased 22 per cent, but the rate for the age group from one month to one year decreased 39 per cent, almost double the neonatal rate reduction (Table VI). It is in the neonatal period that our serious problem lies. Incidentally, there are as many stillbirths as there are neonatal deaths. This is another problem of great concern and is closely associated with neonatal mortality.

TABLE IX. PERCENTAGE DISTRIBUTION OF INFANT DEATHS BY CAUSES

Minnesota, 1949 and 1939

	Prematurity		Other prenatal and natal causes		All Others	
	1949	1939	1949	1939	1949	1939
Under 1 Year	37.4	35.6	40.9	34.2	21.7	30.2
Under 1 Month	49.0	50.6	33.3	31.4	17.7	18.0
Under 1 Week	53.0	54.4	32.6	33.0	14.4	12.6
Under 1 Day	57.7	62.3	32.5	29.3	9.8	8.4

In 1939, 70 per cent of all infant deaths occurred during the neonatal period, with more than half this number occurring under one day of life (38.7 per cent). A total of 21.7 per cent died between one day and one week, and 9.5 per cent died between one week and one month (Table VII). In 1949, there was an increase in the deaths during the neonatal period to 75 per cent with a marked increase occurring in the age group one day to one week. These deaths were due chiefly to prematurity. Only 25 per cent of all infant deaths occurred between one month and one year but this age group showed the greatest reduction.

The chief causes of neonatal deaths are the same as the infant deaths except that prematurity is now responsible for one-half instead of only one-third of all deaths during the first thirty days of life, both in 1949 and 1939 (Table VIII). Congenital malformations and birth injuries make up one-third of the deaths in this period, with an increase in malformations but a decrease in birth injuries in 1949.

The percentage of deaths due to prematurity and other prenatal and natal causes increases progressively from those occurring in the group "under one year" (78.3 per cent) in 1949 (Table IX) to the highest percentage in the group "under one day" (90.2 per cent). A similar progressive increase occurred in 1939.

A Program for Further Reduction of Maternal and Infant Deaths

1. Further reduction in maternal mortality requires:
    (a.) Continued emphasis on competent obstetrical care.
    (b.) More extensive and more adequate prenatal care which must include good nutrition practices.
    (c.) Modern hospital facilities with adequately trained personnel.
    (d.) Periodic surveys of maternal mortality to determine causes of, and responsibility for, such deaths. These findings will be utilized by medical societies, hospital staffs, and teaching institutions for undergraduate and postgraduate instruction in the further reduction of preventable maternal deaths.
2. A consideration of infant mortality leads to one of the most important problems in preventive medicine; namely, a reduction in the number of deaths during the prenatal and neonatal periods which, of course, include stillbirths.
    (a.) A study of infant deaths, perhaps limited to the neonatal period, similar to the survey now being carried out on maternal mortality by the State Medical Association, may be helpful in reducing infant mortality by emphasizing the problems requiring more concerted attention.
    (b.) Consideration of the problems of prematurity in developing a statewide program to reduce the mortality from this leading cause of infant deaths.
    (c.) Study of the relationship of viral diseases and various dietary factors during pregnancy; improved surgical skill and pediatric care to a possible reduction in mortality due to congenital malformations.
    (d.) Decrease in birth injuries by competent obstetrical care.
    (e.) Increased use of the newer antibiotics in pneumonia.
    (f.) Refresher courses in obstetrics and pediatrics at the Center for Continuation Study and/or regional seminars.
    (g.) Modern hospital facilities in rural areas, adequate pediatric nursing, con-

SOLITARY PYOGENIC LIVER ABSCESS

Review of Literature and Report of Case

LAWRENCE M. LARSON, M.D., Ph.D. (Surg.)
and
JOHN H. ROSENOW, M.D., M.S. (Surg.)
Minneapolis, Minnesota

ABSCESSES of the liver may be classified into two main groups: (1) amoebic, which are usually single and which are associated with intestinal amebiasis, and (2) pyogenic. The latter are single or multiple and are usually due to: (1) infection in areas drained by the portal system; (2) spread from contiguous structures, e.g., acute cholecystitis, gastric or duodenal ulceration, or subphrenic space infection; (3) trauma by penetration from without or by infection in a hematoma with organisms already present in the liver; and (4) blood-borne infections via the hepatic arteries.

Some authors make no attempt to separate multiple from single liver abscesses but most feel that such a distinction is important, mainly on the basis of the prognosis and the therapy of this condition. Rothenberg and Linder, in reporting twenty-four cases of solitary pyogenic abscesses, expressed the conviction that the single liver abscess is most often of unknown or doubtful etiology, usually cannot be proven of portal vein origin, and only rarely is associated with pylephlebitis or portal vein thrombosis.

Some authors such as Ochsner, DeBakey and Murray do not separate pyogenic abscesses into two such groups in their analysis of forty-seven personal and 139 collected cases of pyogenic abscess of the liver. Yet they do state that from the prognostic and therapeutic standpoints it is important to make this differentiation if possible.

It is also extremely important to differentiate if possible the pyogenic hepatic abscess from amebic abscess, especially before the amebic abscess becomes secondarily infected. After such secondary infection has occurred, the clinical picture, the prognostic and therapeutic implications become similar to those of the pyogenic abscess.

Bacteriology

In the majority of the non-amebic abscesses the most commonly found organisms are the streptococci, staphylococci and bacillus coli, although almost every type of bacteria has been found in isolated instances. In almost half of the reported cases the pus has been sterile. Blood cultures in pyogenic abscesses are usually sterile.

Pathogenesis

The mode of origin of a solitary abscess in the liver according to most authors is considered to be a blood or lymph stream infection, probably by way of the hepatic artery from a focus such as an upper respiratory infection, carbuncle, influenza, et cetera. In Rothenberg and Linder's cases such a condition accounted for about one half of the individuals. In the other half no etiologic factors could be determined. In only two of their twenty-four cases was a portal vein or bile duct infection responsible. In other words the process is comparable to that of the production of a carbuncle of the kidney or osteomyelitis. Practically all these solitary abscesses occur in the right lobe and most of them involve the dome of the liver.

In multiple abscesses of the liver, the etiological process is one of suppuration in the portal system or biliary system such as suppurative appendicitis or cholecystitis, chronic ulcerative colitis, et cetera. In other words, the infection reaches the liver through the portal blood stream.

Diagnosis

Usually in the case of solitary pyogenic abscess of the liver there is a history of two to four weeks duration, with fever and occasional chills. Malaise and asthenia are pronounced. Indefinite, dull pain in the right lower thoracic region or right upper abdominal quadrant frequently gives the first hint of localization of the pathologic process. Localized intercostal pain is quite often present. Liver tenderness is usual, either on deep pressure with a single finger in an intercoastal space, or on palpation of the edge of the frequently enlarged liver, below the costal margin. This pain is usually directly over the abscessed area, and is non-radiating and constant. It may be dull or sharp, but rarely is it necessary to use heavy percussion to elicit this tenderness. Rapid loss of weight and

---

Presented before the Minneapolis Surgical Society, March 2, 1950.

strength are prominent features, but interestingly, nausea and vomiting are present in only a small percentage of cases. As a matter of fact, nausea and vomiting are a rather rare accompaniment of this disease, and this is of special significance since so few surgical abdominal conditions lack this symptom. Therefore, this absence of nausea and vomiting is an important diagnostic feature. The liver is usually enlarged; a few cases have a palpable right upper abdominal mass; some spasticity of the rectus muscle on the right is usually noted, but is not marked. Limited expansion of the right chest is occasionally seen, and an elevated, fixed diaphragm seen on fluoroscopy is the rule. Other pulmonary signs present are râles at the right base and a small right pleural effusion. Rarely, a palpably enlarged spleen is found. Usually no evidence of ascites is noted. A leukocytosis of 16,000 to 28,000 is the rule and the neutrophiles may average 86 per cent.

In multiple liver abscesses, the symptoms, as one would expect, are more severe as a rule than those in which there is a solitary abscess. The fever is higher and more spiking, jaundice is more common, the liver is larger, and tenderness and spasm of the overlying muscles is greater. The diagnosis in this type can usually be made on the history of a preceding infection in the intestinal tract, whereby the offending organisms have opportunity to reach the liver via the portal or biliary system.

The amebic abscess can usually be distinguished by the previous history and findings of the ameba. In this disease the liver abscess (which occurs in 4 to 5 per cent of individuals with amebiasis in this country) has a characteristically slow onset over months or years, and there is present a minimum of constitutional reaction such as chills, fever and pain. It is true that in many cases the Endamoeba histolytica cannot be demonstrated, yet the history, a trial on antiamebic therapy, and other features of the disease will differentiate this condition from the other types of liver abscess, single or multiple. Of course after an amebic abscess becomes secondarily infected, it must be regarded as a pyogenic one.

Liver abscess must be differentiated from cholecystitis, subphrenic abscess, suppurative lesions of the right kidney and early pneumonia. Disease of the gall bladder can usually but not always be differentiated by a carefully taken history. Previous attacks of pain, intolerance of fatty foods, jaundice and difference in location and the type of pain and tenderness are usually of great help. The pain in liver abscess is steady and directly over the liver substance and not over the gall-bladder area. That in gall-bladder disease is intermittent, radiates to the back and is unbearable. Of course in acute cholecystitis the differential diagnosis is confusing although the enlarged gall bladder can usually be palpated as a tender mass. Subphrenic abscess tends to produce pain on deep inspiration, it usually radiates to the scapular region, and is frequently preceded by an infection within the abdomen. X-ray findings of pus beneath the diaphragm should make the diagnosis. However, when there is an abscess that points to the right dome of the liver, the diagnosis may be difficult. Suppurative lesions of the kidney may be difficult to differentiate from those cases in which the liver abscess involves the lower portions of the right lobe of the liver, because of the pain produced in the right loin. However urinary findings will be of assistance in this differentiation. Early pneumonia may give rise to pain in the right lower chest, fever and chills, but with rapid development of roentgenologic signs in the lungs, and the absence of enlarged liver, et cetera, one may usually differentiate the two conditions. In the differential diagnosis of liver abscess one should always remember that nausea and vomiting are most frequently absent probably because of the lack of peritoneal irritation. In practically all other surgical conditions of the abdomen this symptom is present. Constipation and diarrhea are also almost always absent.

Complications

Since most of these abscesses are on the dome of the liver, the infective process is likely to advance upward and involve the pleura or lungs. Consequently pleurisy with effusion, empyema and even rupture into the lung itself may occur. If the spread is downward the abscess ruptures into the peritoneal cavity. The resulting peritonitis is especially dangerous and the condition then presents the picture of a major abdominal catastrophe.

Prognosis

This varies of course with the location of the lesion, its early recognition, the type of organism responsible, and the multiplicity of the abscesses present. If removal of the pus is not carried out, the mortality rate is 100 per cent. In large series of cases, various authors report all the way from 37.5 to 60 per cent mortality. With the advent of antibiotics it can reasonably be expected that great improvement in results will be achieved. No large series of cases has been reported since these drugs have been used.

Treatment

The classical treatment of solitary pyogenic abscess is incision and drainage. It is repeatedly emphasized in the literature and considered highly important that contamination of either the peritoneal or pleural cavities be carefully avoided, since it has been shown that the mortality rate rises sharply whenever this occurs. If there is evidence of localization of the abscess in the anterior or antero-inferior surface of the liver, the technique described by Clairmont may be used. Briefly, this consists of using a subcostal incision, with mobilization of the parietal peritoneum from the lower surface of the diaphragm, when drainage of the abscess can usually be done extraperitoneally. If it cannot, adherence to the visceral and parietal peritoneum should be induced by packing with iodoform or other gauze, and drainage done through this area at a subsequent stage, two to three days later.

If there is no evidence of localization anteriorly, the retroperitoneal approach described by Ochsner may be employed. The twelfth rib is resected subperiosteally. A transverse incision is made through the bed of the resected rib at the level of the spinous process of the first lumbar vertebra. The reason for this is that the pleura never extends below the level of the spinous process of the first lumbar vertebra. The retroperitoneal space between the upper pole of the right kidney and the inferior surface of the liver is entered. The parietal peritoneum is mobilized from the under surface of the diaphragm, and the abscess drained.

Reports of the treatment of solitary liver abscesses since the advent of the antibiotics have been few. Kisner's cases are of great interest in this connection. In the second of his three cases, while waiting for adequate adhesions to wall off the disease process, penicillin was given parentally and also injected into the abscess following aspiration. At the second stage operation, several days later, the abscess cavity was found to contain only a few cubic centimeters of bloody fluid. His third case received penicillin for forty-eight hours pre-operatively. At operation, the pus evacuated was found to be sterile on culture.

Case Report

The patient is a thirty-six-year-old married white man who was first admitted to the hospital on April 20, 1948, with the chief complaint of severe steady pain in the epigastrium and right upper abdominal quadrant of one day's duration.

Past History.—This patient had had a long history of pain in the lumber portion of his back dating back to 1936. In 1939 removal of the inferior portions of the spinous processes of the first, second and third lumber vertebrae with accompanying ligaments was performed. In 1942 a protruded fourth lumbar intervertebral disc was removed. In 1943 a recurrent protruded intervertebral disc was removed and a spinal fusion performed. However, he continued to have difficulty with his back.

He had also had a history of recurrent spells of diarrhea during periods of severe nervous strain dating back about two years, consisting usually of watery stools after each meal. In 1947 he had been studied from this standpoint at the Mayo Clinic at the time of one of his many admissions there for his back trouble, and it was felt that the cause of the diarrhea was on a functional basis. The investigation at that time included many negative stool examinations.

Present Illness.—The day before admission the patient noted an intermittent, vise-like severe pain in the epigastrium and right upper abdominal quadrant, not crampy or colicky. It occasionally radiated through to the middle portion of the right back at about the level of the eighth to the twelfth thoracic vertebrae. This he stated was separate and different from his old back complaint. He had noted a slight fever in the preceding twenty-four hours, but no chills. He had been mildly nauseated, but had not vomited. There had been no jaundice, nor any diarrhea or abnormalities of the stools. He had had a mild "head cold" about three to four days before admission with a mild dry cough.

On entrance into the hospital, the patient's temperature was 102° F., the pulse was 100, respirations were 18. The blood pressure was 132/70. He was flushed and perspiring and was in acute distress. A general examination revealed a diffuse tenderness and moderate rigidity in the right upper abdominal quadrant. No rebound tenderness was elicited, and no masses were palpated. There was moderately hyperactive peristalsis heard upon auscultation of the abdomen.

X-rays of the chest and abdomen were interpreted preoperatively as negative. On critical review of the chest x-ray postoperatively in conference with the roentgenologist, it was felt that there was a minimal infiltration at the left base and left cardiac border, consistent with a mild broncho-pneumonia. The diphragm shadows were clear and at normal levels. The white count was 22,100, with 86 per cent neutrophiles. The sedimentation rate showed a fall of 45 mm. in one hour. A urine examination was entirely negative except for a faint trace of albumin. The serum amylase was 305 mg. per cent, somewhat above the 200 mg. per cent considered normal at this laboratory. This moderate elevation of the serum amylase was considered to be suggestive, but not diagnostic enough to warrant ignoring what appeared to be a quite typical picture of acute inflammatory disease of the gall bladder. A tentative diagnosis of acute cholecystitis was made and the patient was operated upon seven hours after admission.

The abdomen was opened through a long right rectus incision. A complete exploration of the abdomen was made but revealed only the presence of a chronic inflammation of the gall bladder, which was thereupon removed. The common duct appeared entirely normal. Palpation of the pancreas revealed no abnormalities. Pathologic examination of the gall bladder showed evidence of a mild inflammation characterized microscopically by lymphocytes and fibrotic changes in the wall.

Postoperatively, the patient was carried on continuous nasal suction for the first three days. The rectal temperature ran from 100° to 101° F. for the first four days and was normal thereafter. He was given large doses of antibiotics daily for ten days. The infiltrative process at the base of the left lung was shown to have disappeared completely by a chest x-ray taken two days before his discharge from the hospital on the eleventh postoperative day. An electrocardiogram on the fourth postoperative day was interpreted as being within normal limits.

Four weeks later, the patient was re-admitted to the hospital on May 27, 1948, giving the history that for a short time after returning home he had done well, but in about one week had begun to pursue a downhill course, with malaise, anorexia, recurring fever, and gradual loss of 20 pounds in weight. In the week prior to admission he had suffered from nausea and vomiting and had been unable to retain anything solid taken by mouth. He had felt quite distended and had belched frequently. No spontaneous stool had been passed in this week.

When first seen, he presented evidence of weight loss and severe dehydration. He appeared acutely ill, and complained of a steady rather severe pain in his right upper abdomen. His temperature was 99.8° F., the pulse 92, the respirations 16. The blood pressure was 108/68. A firm rounded tender mass was palpable in the midportion of the upper epigastrium. It was non-movable and seemed semi-fluctuant. It was approximately 6 to 8 cm. in diameter, although its edges could not be clearly defined.

A scout film of the abdomen showed no evidence of intestinal obstruction, gastric dilatation, or other pathologic conditions and a chest x-ray was negative. The hemoglobin was 14.9 gm., the red count was 4,800,000, the white count 13,500 with 78 per cent neutrophiles. The sedimentation test showed a fall of 96 mm. in one hour. The blood urea nitrogen was 16 mg. per cent, the CO_2 combining power was 73 vol. per cent, and the chlorides were 496 mg. per cent. The urine was entirely negative. A blood culture showed no growth in forty-eight hours.

For the first two days after admission, he was allowed only small amounts of liquids by mouth, and he was given intravenous fluids in large amounts with supplementary parenteral vitamins, followed by distinct improvement. He had a daily afternoon elevation of temperature, varying from 100.6° to 101.2°. During this time the mass described in the upper abdomen increased somewhat in size, and became excruiatingly tender.

Under general anesthesia, forty-eight hours after admission, an incision was made directly over the abovementioned mass. The tissues of the various layers of the abdominal wall were moderately edematous and quite indurated. The peritoneum was opened and in the anterior edge of the right lobe of the liver a rounded mass was seen covered with whitish, thickened liver capsule. An incision was made into the mass, and about 300 to 400 c.c. of thick cream colored pus were evacuated. The pus was not the cholocate color described as being characteristic of an amebic abscess. A cautious digital exploration of the abscess cavity was done. Further general exploration was not done although it might have been well to have taken a biopsy of the wall of this abscess. A soft Penrose drain was placed deep in the abscess cavity and brought out through the incision which was then closed about it in layers.

In twenty-four hours the patient's temperature dropped to normal and remained so thereafter. For the first three days, he was carried on parenteral fluids, large doses of antibiotics, a gradual increase in oral intake and by the eleventh postoperative day, the patient was feeling fine, eating well, and had gained eight pounds in weight.

A direct culture from the contents of the liver abscess at the time of surgery showed streptococcus viridians. No amebae were seen on fresh direct smear. Postoperatively, four successive stool cultures were negative for pathogenic bacteria and for entameba histolytica in either vegetable or encysted forms. A proctoscopic examination showed a perfectly normal rectum and rectosigmoid for a distance of 25 cm. A fresh smear taken from the bowel wall during this examination was negative for entameba histolytica. Roentgenologic studies of the colon gave negative results.

The drainage from the wound was surprisingly small and was purulent for the first few days only. The drain was gradually shortened and was removed on the fourteenth postoperative day.

When seen about a month later, the patient stated that he was eating well, his strength was excellent, and he had had no symptoms referable to his abdomen. The wound healed normally.

Six weeks postoperatively the patient was in excellent health, except that he had been having occasional loose stools after meals for a few days. As in the past, these symptoms coincided with a period of excessive nervous tensions.

Discussion

The exact etiological basis for the pyogenic liver abscess in this individual is still a matter of some conjecture, although the possibility of its being amebic in origin has been pretty well eliminated. The most likely explanation is that the abscess was primarily a so-called solitary pyogenic abscess probably of metastatic origin, such as those described by Rothenberg and Linder possibly arising from a respiratory infection. Its incipient stages may have been responsible for the symptoms that led to his cholecystectomy.

A number of other possibilities might be developed, for which there is only little evidence, and certainly no definite proof.

1. Cholecystic disease might have initiated the disorder. This is unlikely. In a single reported case where biliary tract disease was the etiological agent, the abscess resulted from direct extension of an acute suppurative or gangrenous cholecystitis, quite the contrary to this case. In a review of all the available literature from 1930 to the present dealing with complications and mortality following biliary surgery, only one case of liver abscess was described (Doran et al). The articles consulted represented about 45,000 cases. However it is readily understandable that many of these complications would go unreported.

2. A branch of the right hepatic artery might have inadvertently been ligated at the original cholecystectomy, producing an infarct which became secondarily infected, with abscess formation. This is unlikely because one would have expected in the postoperative period more immediate signs and symptoms of something drastic taking place, whereas the patient made a normal recovery. Also, this theory offers no explanation for the definite signs and symptoms that led to the cholecystectomy.

3. Amebiasis may have been the underlying factor all along, with an amebic hepatitis having been present for several years prior to the first admission, which progressed to abscess formation, and the abscess becoming infected with secondary invaders producing the symptoms and signs leading to his cholecystectomy. The ubiquitous postprandial loose stools seem to favor this amebic theory, but the following facts are rather good evidence against this: (a) The presence of the regularly occurring "diarrhea" so suggestive of an exaggerated gastro-colic reflex, yet the patient maintained his normal weight and general good health. (b) The failure on many stool examinations, properly secured, to demonstrate the parasite. The presence of a diarrhea in amebic infestation usually means left colon involvement, and there should have been some positive evidence in the many stool examinations, repeated proctoscopic examinations and colon fluoroscopic examination. (c) The failure to demonstrate any amebae in the pus from the abscess. These should have been found since the abscess was a recent one, and it has been shown that the organisms are usually present in this type of abscess. In long standing cases where the abscess wall is fibrotic it is necessary to scrape the wall to obtain the organism. Furthermore the pus was creamy in color and not the typical "chocolate sauce" variety which is so characteristic of amebic abscess. (d) The failure of the patient's symptoms to be affected in any way by a therapeutic trial of specific anti-amebic medications, carried out some months later at home.

4. A mild chronic relapsing pancreatitis with secondary cholangiocholecystitis and hepatitis may have started the sequence of events. This possibility has much to be recommended it, but again there is no definite proof. The moderately elevated serum amylase at the time of cholecystectomy is not very good evidence. In this connection, Pemberton, Musgrove and others have recently shown that involvement of the pancreas by an adjacent pathologic process may produce a moderate elevation of the serum amylase.

Summary

1. A case of solitary pyogenic abscess in the anterior right lobe of the liver is hereby presented which was cured by incision and drainage.

2. The pathogenesis of this abscess was most likely a metastatic infection through the hepatic artery arising from a pre-existing respiratory infection.

3. The symptomatology in this case so closely simulated that of an acute cholecystitis, that cholecystectomy was done, only to find that four weeks later the abscess in the liver became obvious.

4. From the prognostic and therapeutic standpoint, it is important to differentiate between solitary and multiple pyogenic abscesses. The solitary types have less violent constitutional manifestations, less pain, and less leukocytosis than do the multiple. In addition, the multiple liver abscesses usually have a pre-existing infection in that part of the abdomen drained by the portal system. Jaundice is more common in the latter type.

5. In the differential diagnosis of pyogenic liver abscess, the most likely conditions to be considered are cholecystitis, subphrenic abscess, suppurative lesions of the right kidney and early pneumonia.

SUBFASCIAL FAT ABNORMALITIES AND LOW BACK PAIN

R. J. DITTRICH, M.D.
Duluth, Minnesota

IN recent years several investigators have called attention to the importance of fat tissue in the subfascial spaces as factors in painful syndromes. Our former concept of fibrositis as a clinical or pathological entity involving muscle or fibrous tissue has been dispelled by the discovery that the painful lesions which were interpreted as "fibrositic" nodules are, in reality, masses of fat tissue which have undergone changes and are causing varying degrees of disability.

The principal contributors to our knowledge of the painful lesions of fat tissues are Copeman and his associates.[1,2] The original studies were made in cases of painful disabilities of the back. After charting the location of the trigger-points, usually represented by a tender nodule of tissue, dissections of the muscular and fibrous tissues in the painful areas were undertaken. It was revealed that the deep fascia of the back was frequently defective or very thin, permitting the fat tissue underneath the fascia to herniate through the defect. Three types of herniation are described: the pedunculated, the non-pedunculated and the foraminal, the latter occurring through the foramina of the lumbar nerves as they pierce the deep fascia. Another form of abnormality in fat tissue is edema of individual lobules, causing pain presumably by tension of the tissues.

Within the confines of the basic fat pattern described by Copeman,[1] the site of predilection for herniation is a narrow strip along the lateral border of the sacrospinalis muscle from the lower costal margin to the iliac crest. Tension syndromes due to edema are likely to arise from the region of the sacrum, from the area of residual fat situated immediately below the rim of the ilium, and from the dorsal fat pad, a diamond-shaped area in the upper part of the back, corresponding roughly to the outline of the trapezius muscle which lies beneath it.

An additional abnormality of fat tissue is described by Copeman as panniculitis, which occurs in abnormally deposited fat, mostly in predictable sites.

Among the etiological factors mentioned by Copeman[1] are endocrine disorders, sodium balance, heredity and exposure to cold environment. Treatment is discussed from the standpoint of diet, endocrines, diuresis and dehydration, physiotherapy, injection and surgery.

Herz[3] reported thirty-one cases in which treatment consisted of surgical removal of the painful lesion. In a later report (quoted by Hucherson and Gandy) his series consisted of 229 cases, of which sixty-seven were subjected to operation. Hucherson and Gandy[5] report thirty-two cases in which surgical treatment was employed. They state that operation was considered necessary in approximately one-fourth of the patients; in the remainder, adequate relief was obtained by injection with local anesthetic. Orr, Mathers and Butt[12] described fibrolipomatous lesions as sources of somatic pain and directly responsible for clinical manifestations which suggest disease of the kidney or ureter. A form of fat abnormality, episacroiliac lipoma, has been described by Hittner[4] who reported a series of fifty cases in which the lesions were removed by operation. Relief of pain in the lower part of the back was obtained in forty-five instances.

In all these reports there seems to be general agreement regarding the nature and the location of the painful structures, the methods of identification, and the high percentage of successful results following treatment.

From personal observations on patients with painful back, it is possible to agree with many points discussed by Copeman and others. Of those who were treated by injection of local anesthetic into the painful or tender sites of the back, it was possible to obtain varying degrees of relief from pain in the majority of cases. In some instances relief was complete and apparently permanent; in others it was incomplete, and recurrence was not uncommon. Efforts were directed toward locating the primary source of the pain, as manifested by localized tenderness. By careful palpation it is usually discovered that the tenderness is distributed over a large area of the lower part of the back, though frequently localized in more clear-cut intensity at certain sites.

Referred pain is a common subjective manifestation. This is frequently noted in the lower extremities, although it may also occur in other portions of the lower part of the back. It is more often unilateral. It is generally accepted that referred pain has a segmental pattern; it occurs within the distribution of the same spinal nerve as that from which the primary pain arises. It is also agreed that sensory innervation of the deep skeletal structures differs greatly from the pattern of dermatomic supply. Our knowledge of these characteristics of deep somatic pain is derived largely from the investigations of Lewis and Kellgren,[10] Kellgren,[7,8,9] Inman and Saunders,[6] Sinclair, Weddell and Feindel,[13] Wolff and Wolf,[14] and many others. The practical significance of referred pain lies in calling attention to a primary focus of pain elsewhere. The source of pain of this nature is rarely located by the patient with any degree of accuracy. If on examination the trigger-point is irritated, reference of pain serves as a valuable aid in identifying the algogenic region.

Referred tenderness is a characteristic of deep somatic pain which, although it suggests a similarity to referred pain, is vastly different in its mechanism of development and usually in its topographic location. This term is applied to sites of hyperalgesia, resulting as secondary phenomena to the primary source of pain. Thus it is possible in many instances to elicit tenderness at numerous points in the lower part of the back or the buttocks, in locations remote from the trigger-point. The degree of tenderness is variable. Where numerous sites of this nature becomes evident, it is often confusing and difficult to locate the trigger-point. It is frequently necessary to determine the point of origin of the pain by a process of elimination—by injection of local anesthetic into successive tender regions. Thus, by a successful injection of the trigger-point, all pain and all tenderness can be abolished; on the other hand, injection of a secondary site of pain is usually effective only in relieving the tenderness at the treated area.

The status of our knowledge of referred pain has recently been defined as follows: "Stated broadly, then, the numerous shades of opinion can be reduced to two opposing beliefs. The first of these is that some mechanism located in the central nervous system is responsible for all the phenomena of referred pain, and the second is that these phenomena are produced by events taking place in the periphery. It is no doubt possible that by considerable amplification of one or other of these theories a hypothesis might be arrived it, which would adequately overcome the objections which could be levelled against it. Nevertheless, the fact remains that, *as they are at present stated,* neither hypothesis is capable of explaining all the observed facts . . ."[13]

Sinclair, Weddell and Feindel[13] suggested, further, the following hypothesis for occurrence of referred pain and tenderness in somatic structures: "The anatomical basis of the physiological processes concerned in the production of referred phenomena is the branched axon. In any given case there are two main mechanisms at work; the first of these is the misinterpretation by the central receiving apparatus of the source of the painful impulses, and the second is the production in the periphery, as a result of antidromic impulses, of metabolites which at first stimulate the nerve endings there and later damage them. It is probable that the operation of the first of these mechanisms gives rise chiefly to referred *pain,* while the chief result of the operation of the second is referred *tenderness,* but both mechanisms must be considered in relation to either phenomenon."

"Anesthetization of the area of reference will affect the second mechanism in two ways, first by the interruption of the painful impulses arising there on their way to the central nervous system, and secondly, by the blocking of the antidromic impulses which are activating and perpetuating these painful impulses. The result of this procedure is therefore to abolish the pain and tenderness resulting from the operation of the peripheral chemical mechanism."

A study of records indicates that the most common manifestation found in cases of painful back is tenderness in the sacral paraspinal region. This may involve one or both sides of the midline. In case of a bilateral site of tenderness in the sacral region, usually only one side harbors a lesion which is sufficiently painful to cause disability and therefore require treatment. In many instances when the trigger-point of pain is located in that area, injection with local anesthetic will provide relief for indefinite periods of time, varying from weeks to months and sometimes permanently. When pain recurs after short intervals or in cases where no relief is obtained beyond the duration of the local anesthetic effect, surgical removal of the painful lesion is indicated.

Another location in which abnormalities of fat tissue develop as primary sources of pain is the ilio-lumbar area, along the lateral margin of the sacrospinalis muscle. The most common condition at this site is a herniation of fat lobules through the deep fascia.

It is necessary to mention that the apparent ease with which other observers are able to identify the painful lesions represents an understatement or a misunderstanding of the total picture of such abnormalities. Most patients do not present the typical clinical manifestations, consisting of a history of pain and a palpable, sensitive nodule, so easily located and treated; many patients, in fact, do not present any nodule or enlargement which is significant. In addition, tenderness is often elicited only on heavy pressure and after meticulous search in the suspected location. When multiple sites of tenderness are encountered, it becomes necessary to determine the primary source of the pain. Apparently Moes[11] has recognized similar situations in the subcutaneous nodules lacking the trigger-point tenderness and the typical relief on injection. The procedure of local anesthetization is necessary in all cases for positive identification of the primary source of the pain; it is especially useful when pain and/or tenderness are widespread and where a clear-cut radiation of pain cannot be elicited so that the patient is able to identify it as that which he experiences.

The technique of injection consists of locating the painful area with the point of the needle. This requires the patient's co-operation. The site of the pain is infiltrated and, after anesthesia is obtained, the point of the needle is manipulated to disrupt the tissues from which the pain arises. It is advisable to warn the patient that the pain may be aggravated temporarily after the local anesthetic is absorbed.

Surgical treatment, when necessary, is carried out under local anesthesia. In this, the patient's co-operation is needed. After infiltration of the skin, the incision is made and dissection is carried out down to the fascia. The fascia is examined visually and by probing with a needle for the purpose of identifying the location of the abnormal tissues. It is sometimes possible to incise the fascia without causing excessive pain. It is always desirable, if possible, to locate the trigger-point accurately prior to anesthetization of the deep tissues. The deep fascia is then incised and the abnormal tissues are removed. As there is frequently a prolonged and a persistent accumulation of blood and serum from the surgical field, it has become a practice to leave a small drain in the wound for a period of five to seven days, after which a sinus is formed. This usually heals in three to four weeks. Ordinarily patients need not be hospitalized.

Surgical treatment consisted of eleven operations on ten patients. In three the operative site was the ilio-lumbar region, at the lateral margin of the sacrospinalis muscle. In one of these, the abnormality consisted of swelling of several fat lobules underneath a very thin portion of the lumbodorsal fascia, which was bulging but not ruptured. In a second, a bilateral operation showed on each side small herniations through the fascia. In a third case, a marked sciatic scoliosis and pain in the gluteal region were associated with tenderness in the ilio-lumbar area at the level of the iliac crest. These features were satisfactorily corrected on two different occasions by preoperative injection of procaine. At operation, the painful area was identified by the patient in a small patch of the lumbo-dorsal fascia. This was incised. The only feature which appeared significant as an abnormality was a firm adherence of several small masses of fat tissue to the ventral surface of the fascia. This was resected. Postoperative progress was satisfactory for five days, after which the pain and the curvature reappeared. These manifestations were relieved by evacuation of a small hematoma. During the next two weeks a firm swelling, suggesting a cyst, developed in the operative site, and with this, a recurrence of the pain and the scoliosis.

In seven patients the sacral region was explored; the operation was bilateral in four. The findings here consisted of swollen lubules of fat tissue underneath the deep fascia. The enlarged lobules or "bubbles" of fat were removed together with other portions of fat tissue in the operative field which were apparently normal. The swelling was the only significant abnormality which was encountered. Microscopic examination showed normal fat tissue.

All these patients were afflicted with varying degrees of disability due to pain in the lower part of the back. In the majority of these, the pain was referred elsewhere, most commonly to the lower extremity. In one case the back pain was associated with coccygodynia. In two cases pain referred to the upper portion of the back was relieved following the operation. In four patients, headache was a prominent symptom, apparently related to the pain in the lower part of the back. These unusual phenomena require a more detailed analysis which is planned at a later date.

The immediate postoperative results have been uniformly satisfactory. Relief from pain has been prompt in all cases and, with one exception, has been maintained during the period of observation, varying from two to twelve months.

Summary

From a review of the literature and observations on ten patients, it is evident that abnormalities of subfascial fat tissue constitute an important factor in the development of painful disabilities of the back. The principal features responsible for clinical manifestations are edema and herniation of the fat tissue. A knowledge of the principles and the mechanism of referred pain is essential for adequate evaluation of the clinical phenomena.

SOLITARY PYOGENIC LIVER ABSCESS

(Continued from Page 592)

6. The complications of these abscesses are concerned with rupture of the abscess into the pleural or peritoneal cavities, lungs or surrounding viscera.

7. With proper treatment, the prognosis in the solitary type of liver abscess is much better than that in the multiple. In large series of cases the former carry a mortality rate of 37.5 to 60 per cent, while in the latter it is usually given as 90 to 95 per cent. Without treatment the mortality rate in either type closely approaches 100 per cent.

8. Treatment consists of early incision and drainage of the abscess either anteriorly or posteriorly in such a fashion as to avoid contamination of the pleural or peritoneal cavities.

9. With the present day advantage of the antibiotic drugs much improvement may be expected in the prognosis of these abscesses, since most of them are due to the staphylococcus, streptococcus and colon bacillus.

HEMOLYTIC TRANSFUSION REACTION IN OBSTETRICS

Report of Case

ANN W. ARNOLD, M.D.
Minneapolis, Minnesota

DOUBTLESS hemorrhage is now the most important complication of obstetrics. Transfusion is the immediate stop-gap in treatment and no doubt accounts for decreasing mortality. Nevertheless, in practice one is at times sharply made to feel the inherent danger of this now commonly used procedure. These dangers are illustrated by the following case.

The case is that of a twenty-seven-year-old woman, gravida III, who came into the hospital in the fifteenth week of her pregnancy bleeding profusely and having severe cramps and faintness. She had not to her knowledge passed her fetus. Examination showed a very pale young woman with a pulse of 108, and blood pressure of 100/52. The uterus was soft and the size of a three and a half months' gestation. Her hemoglobin was 13 grams on admission and leukocytes 3,150. In a few hours the hemoglobin dropped to 9.9 grams, and 500 c.c. of whole blood, type AB, Rh positive (homologous), was given with 1000 c.c. of 5 per cent glucose and saline. Ergotrate also was given intravenously. She was then taken to the operating room. Under 24 c.c. of pentothal anesthesia intravenously, examination showed the vagina filled with 500 c.c. of clots. Fetal membranes and large pieces of placenta were removed and the cavity of the uterus thoroughly cleaned. The report of the pathologist was "incomplete abortion." The patient's condition was satisfactory except for pallor and a pulse of 104 and blood pressure of 92/66.

That evening her hemoglobin had dropped to 7.8 grams, and a second transfusion was ordered. On the third hospital day a second transfusion of O positive blood was started at 4:30 p.m. and discontinued at 5:40 p.m. Soon thereafter she was noted to have headache, backache, and an indescribable tense feeling in her trunk as though she would burst. Her pulse was now 130 and regular. She vomited considerable cherry colored liquid flecked with blood. This was chemically positive for blood. Soon there was diarrhea with gross blood. She presented an appearance of profound shock. She was given atropine and benadryl with no apparent change. At 8:15 she was catheterized and 100 c.c. of bile-stained urine obtained. This showed destroyed red cells—loaded—and 4-plus albumin. She received 500 c.c. of sodium lactate solution at three different intervals in an attempt to keep the urine alkaline. The day following transfusion, 165 c.c. of urine was obtained in three catheterizations. On the second day following transfusion, no urine whatever was passed; on the third day she passed 5 c.c. of very thick urine; on the fourth day no urine was passed; on the fifth day 5 c.c. was passed; on the sixth day she passed four small specimens, a total of 10 c.c.; on the seventh day she passed 38 c.c. in four voidings; on the eighth day she passed 140 c.c. on two occasions, and by the eleventh day she had increased her output to 2485 c.c. of urine. The first two urines showed 4-plus albumin and were positive chemically for occult blood. Albumin was 4-plus to the sixth post-transfusion day. On the eighth post-transfusion day there was 1-plus albumin and thereafter it contained no albumin. On the day of reaction, the direct Van den Bergh was 1.3 mg. per cent, and the indirect Van den Bergh was 3.4 mg. per cent. The next day it was 0.13 mg. per cent, and 1.85 mg. per cent.

The blood urea nitrogen on the day following reaction was 29 mg. per cent. It rose rather evenly to a high of 110 mg. per cent on the tenth post-transfusion day and was 84 mg. per cent on the day of discharge. Several weeks later it was 11 mg. per cent.

The CO_2 was 75 vol. per cent on the day following her reaction and varied from 51 to 63 per cent and was still 51 vol. per cent on the day of discharge.

The blood chlorides were rather stable. On the third day their value was 542 mg. per cent; was lowest (482) on the fifth day, and 572 mg. per cent on the day of discharge.

The hemoglobin dropped to 7.4 grams following transfusion reaction, was 8 grams on the seventh day, and again 7.8 grams on the fourteenth day.

The white cell count was highest on the third day when it was 32,520, and gradually dropped to 12,300 on the tenth day.

The blood pressure remained remarkably stable after being at shock level of 80/55 some nine hours after reaction. There was one recording of hypertension on the thirteenth day of 150 systolic and 85 diastolic. This promptly returned to a normal level.

Her weight normallly was about 128 pounds. When taken on the third post-transfusion day it was 136 pounds, and reached 141 pounds on the seventh day. It then orderely receded with increase in urine volume to 120 pounds on discharge.

Except for the post-transfusion fever reading of 103° the temperature promptly came down and remained at 100° or less for the rest of her hospital stay. The pulse likewise, except for the early reaction, remained mostly around 80.

Her gastrointestinal tract had an immediate convulsive session of vomiting and diarrhea. This quieted down to occasional vomiting of small amounts of brown or greenish fluids. She was willing to co-operate in food intake. The most acceptable food seemed to be the pellets of butter and sugar, as suggested by Dr. C. D. Creevy. Normal appetite came back in about two weeks.

The general attitude of this woman throughout this gruelling experience was quiet, even lethargic. She talked very little and at first moved very little. She stated she had soreness especially in the lumbar region. She was kept in bed eleven days. She was very pale and had some trunk and facial edema before the diuresis, but never any pitting edema of the extremities.

The treatment, as indicated in the chart, was aimed at adequate nutrition, water, and electrolyte balance during the time it takes for the damaged kidney to recover. Diathermy to the kidney areas twice daily was given empirically, believing it might stimulate circulation in the kidney through relaxation of vasospasm.

There seems to be little hesitancy to place this dramatic case as one of transfusion reaction. Of the three types of reaction there are: (1) physical and chemical reaction, (2) allergic or urticarial reaction, (3) hemolytic reaction. Among the latter there are: (a) intra-group type of Rh reaction or "cold" hema-agglutinins, (b) gross incompatibility, (c) dangerous "universal" group O donor.

Strumia stated that when using group O blood it would seem desirable to use those blood with titers of less than 1:60 isoagglutinins. Witebsky et al, feel that this precaution is unnecessary if purified A and B substances are added to the blood in order to neutralize the isoagglutinins. Straumia further suggests that in need of extreme precaution one may use the biological test of giving 100 c.c of the blood and comparing five hours later the serum bilirubin of the patient's blood then with the pre-transfusion level.

The seriousness of this condition, in Strumia's opinion, is modified by several factors. In general, in those with previous kidney damage, the outlook is unfavorable. Those receiving less than 250 c.c. of blood will usually recover. Those receiving 500 c.c. or who have had previous transfusion reactions will usually die.

The incidence and death totals are best illustrated by the groups and statistics collected by Wiener and shown in Table I.

In considering some of the literature on this subject, the most interesting discussion is on the pathogenesis of the sequelae of hemolytic reaction in the kidney. The varieties of theory on kidney pathology are briefly four: (1) blockage of renal tubules, (2) anaphylaxis, (3) nephro-toxic substances released from hemolysis, (4) ischemia of kidney from vasoconstriction.

The theory, from the laboratory studies of Dodds, DeGowin and Richards, of blockage by acid hematin crystals seems not to be substantiated clinically, as in a number of deaths there were few with blocked tubules. Strumia states that in four of his cases there were none blocked.

TABLE I. TRANSFUSION STATISTICS

	Year of Report	No. of Transfusions	No. of Hemolytic Reactions	Deaths
		Fresh Blood		
Wiener*	1917-1941	19,275		39
Kilduffe and De Bakey	1917-1941	43,284	80	45
		Stored Blood		
Weiner*	1939-1941	8,236		9
N. E. Deaconess Blood Bank	1942-1946	13,000	2	1
Mass. Mem. Blood Bank	1940-1946	6,464	1	0
Hartford Hosp. Blood Bank	1941-1946	16,000	2	0
Mass. Gen. Hosp. Blood Bank	1942-1946	28,588	8	2
Peter B. Brigham Blood Bank	1945-1946	2,140	3	0
Children's Hos. Boston Blood Bank	1946	1,200	1	0
Boston Lying-In Blood Bank	1946	452	1	0
Total		76,080	18	12

*These are the totals of a group of statistics collected by Wiener and presented in his book.

The theory of anaphylaxis is opposed by two facts: one is that hemolytic transfusion reaction usually follows a single dose of whole blood; and, second, urticaria has never been seen with fatal post-transfusion reaction.

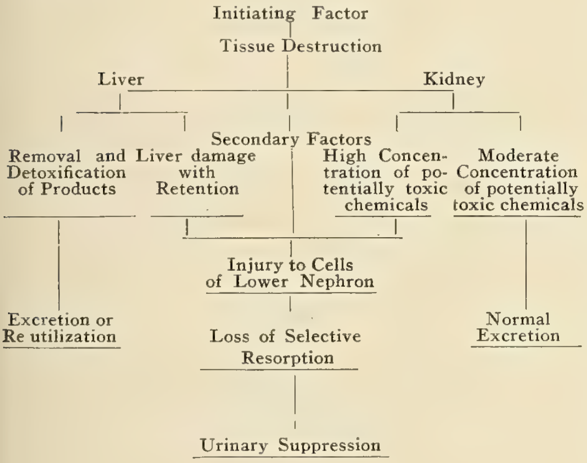
That there is a nephro-toxic substance released from blood hemolysis is difficult to prove. Hemoglobin of itself is nontoxic. But the protein substances contained in the red cell stroma is likely to be the toxic factor. This toxic factor leads us into fascinating current work that is being done on renal mechanisms and particularly renal circulation as under control of a neurovascular reflex.

Baldwin Lucké, in a monumental work, studied a series of 538 cases from the clinicopathological viewpoint. He states: "It is appropriate to designate all cases exhibiting these renal disturbances no matter what their etiologic background by a single term." This he gave the name of "lower nephron nephrosis." The various causes of this lesion he lists as follows:

1. Crush syndrome
2. Thermal burns
3. Heat stroke
4. Black water fever
5. Chemical poison or sensitivity
6. Alkalosis
7. Hemolytic transfusion reaction
8. Non-traumatic muscular ischemia
9. Toxemia of pregnancy
10. Utero-placental damage

At present, the exact pathogenesis is not too well known. Lucké states: "Several factors are concerned in combination. Among those implicated are: degradation products of myoglobin and hemoglobin, products of tissue breakdown, physiochemical alteration of blood and body fluids, shock and disturbances of renal blood flow resulting in ischemia of the kidney and anuria."

In a recent article by Mauzy and Donnelly, who studied nine cases of urinary depression in the toxemia of pregnancy, they advance the theory that both the liver and kidney are involved. One detoxifies, the other excretes. The liver is the first line of defense and, in case of damage here, the kidney or second line of defense takes over. They have made a diagram in simple explanation (Fig. 1).



Initiating Factor
Tissue Destruction
Liver
Kidney
Secondary Factors
Removal and Detoxification of Products
Liver damage with Retention
High Concentration of potentially toxic chemicals
Moderate Concentration of potentially toxic chemicals
Injury to Cells of Lower Nephron
Excretion or Re utilization
Loss of Selective Resorption
Normal Excretion
Urinary Suppression

Fig. 1.

This article and diagram bring back to mind the term hepato-renal syndrome seen in the literature a number of years ago.

Ward O'Donnell, in 1949, reported three cases to show proof between lower nephron nephrosis and abortion. There was jaundice in two of the three cases and the third had hepatic zonal necrosis. All three had the typical renal pictures. All three had similar uterine findings, namely, necrotic decidua and chorionic epithelium. He says: "In our cases it is probable that the theoretic substances had origin in the retained placental tissue. . . . It is also possible that both factors—a hypothetic vasonconstrictive humoral substance from the ischemic placenta and toxins from invading bacteria—might, by synergistic effect, act on a susceptible neurovascular mechanism to produce reduced cortical flow, a result not obtainable by either acting separately. The role of bacterial toxins may be that of producing hepatic damage sufficient to produce hepatocellular dysfunction and inability to detoxify circulating placental products. These substances would then be free to act unfavorably on the kidneys."

Obstetricians will be particularly interested in the work of British pathologists and physiologists. The syndrome was first noted in the first World War and then forgotten for nineteen years. In the early part of the World War II, Bywaters and Dible in 1942 noted the syndrome in war injuries and called it the "crush syndrome." They reported a characteristic lesion in the lower nephron manifested by degeneration of the epithelium and deposits in the tubules of crystals of blood pigments.

Identical pathological changes were noted by Bratton and James Young in obstetrical anurias associated with abruptio placentae. J. F. Smith, of London Hospital, in examining seventeen necropsy cases of eclampsia, found pigment casts in the second convoluted tubules and ascending limbs of Henle in three. In two of the three cases there had been oliguria. Abruptio has long been believed to have a background of toxemia. Evidence now suggests that abruptio and toxemias (in certain cases) and crush injuries may have a common picture in this lower nephron nephrosis.

From Nuffield Institute (Oxford) comes an important monograph by Josef Truetta et al, "Studies of the Renal Circulation." Here he postulates by animal study that normally the renal cortex receives most of the blood and the medulla the smaller part. The blood reaching the kidney has two potential routes. The path of the greater circulation is through the cortical glomeruli. When blood follows this route, the glomeruli are well filled, urine flow is normal, and the blood in the renal vein is venous. The pathway of the lesser circulation of the vessels is to the medulla and to the juxta-medullary glomeruli. When vascular spasm shunts blood through this route, the flow of urine is decreased and the blood in the renal vein is largely arterial. The primary cause of lower nephron nephrosis is this cortical ischemia due to a shunting of the blood and its toxic products by a neurovascular reflex into the medulla.

It is further postulated that this neurovascular mechanism of the kidney is largely protective. Though there may be complete desquamation of these tissues, they can regenerate in four to ten days, showing the reparative power of the kidneys provided the individual can survive the repair period. Mr. T. L. T. Lewis believes that if there is a sudden release of toxic products into the circulation, as in uterine muscle breakdown from abruptio placentae, the kidney deals first in the protective mechanism of the "Truet a Shunt" so as to save the cortex. If this mechanism is overwhelmed or fails, the delicate cortical vessels are injured, paralyzed, engorged and finally blocked. In the first, we have lower nephron nephrosis and possible recovery. In the second, we have cortical necrosis and inevitable death.

The cause of death in these cases is not uremia. More properly it involves electrolyte balance, acid and base equilibrium and water distribution. The diminution of urine, as studied by Bywaters and Dible, "is now due to excessive, but unselective reabsorption of the glomerular filtrate through the tubules—in other words, leakage back into the blood stream." The kidneys are involved in protein metabolism as they can form urea. Therefore, breakdown in kidney function may give rise to toxic protein metabolites. Uremic death is more than an accumulation of urea, uric acid and creatinine.

Prof. K. J. Franklin and his co-workers have shown what a hair-trigger mechanism the renal shunt can be. Stimulation of a sciatic nerve end or the nerve plexus about the renal artery, the injection of staphylococcus toxin or pituitary extract can instantly bring about the cortical ischemia. Another field that can reflexly evoke the "Oxford shunt" is the so-called "stretch stimuli." This is the distension of hollow organs composed of smooth muscle. Distending the bladder with normal saline solution, stretching the intestine or parts of the pregnant and nonpregnant uterus, similarly are followed by this renal neurovascular response. He advances the hypothesis that the toxemia of pregnancy is, or includes, a progressively increasing tendency for the renal shunt to be brought into operation and that cortical necrosis represents the maximal irreversible result of this tendency.

Conclusions

Though constantly minimized by basic research, transfusion is still a dangerous procedure requiring rigid observation of the known rules. Prevention is paramount. The syndrome of lower nephron nephrosis seems to underlie such clinically diverse conditions as shock, burns, eclampsia, chemical poisoning, muscle injury and intravascular hemolysis.

Recent clinico-pathology and physiological reresearch have revealed some of the facts regarding the cellular pathology and the neurovascular mechanisms in the kidney. Furthermore, those facts seem to apply to body defense mechanisms which heretofore were not thought to be related. These mechanisms are probaly basic to homeostasis.

Though many extravagant methods have been tried in the treatment, the simple maintenance of adequate nutrition and water and electrolyte balance best serves the body in the period of the fourth to the tenth day when, if possible, the kidney cellular damage is repaired. The case reported was followed on this basis, with fortunate results.

PSYCHIATRIC EXPLANATION OF BALDNESS

The April, 1950, issue of *Modern Medicine* condenses "A Theory of the Pathogenesis of Ordinary Baldness" from *Archives of Dermatology and Syphilology*.[1] This ingenious explanation relates baldness to tension of scalp muscles creating shearing stresses in the dermis, with subsequent ischemia and alopecia. "This muscular activity probably survives from a once useful defense mechanism in man's phylogenetic past, when the ears were drawn against the head for protection during attack." The authors believe that anxiety in connection with attacks on personal integrity may elicit this basic defensive attitude.

For years we have carried on personally in our absent-minded way beneath a cranial dome from which, like the Parsee's hat, the rays of the sun are reflected with more than oriental splendor. To us, in our simplicity, it has heretofore been merely a carefree bald head needing no brush and eliciting only the usual good natured "kidding." In summer it has served as a portable landing field for flies, mosquitoes, and the like, but that it was a survival "from a once useful defense mechanism" in our phylogenetic past in which our musculature slicked our ears back has never occurred to us, especially as we have never been able to wiggle our ears, thereby in our youth having lost considerable face in the presence of those who could and did practice this delightfully entertaining sport.

Our personal integrity has been at times attacked, but our defense mechanism, pinned back ears and low wind resistance on top, has worked well on the whole, now we think about it.

The authors say also "The facial expression associated with early baldness is a fixed smile which indicates hyperactivity of the occipitalis." Until now we had considered it only as an expression of good nature, but that was in our preindoctrination period. Ah, well; live and learn.—Editorial *N. Y. State J. of Med.*, May 15, 1950.

PLACENTAL POLYP SIMULATING A CHORIONEPITHELIOMA

Report of Case

F. H. MAGNEY, M.D., F.A.C.S.
Duluth, Minnesota

A PLACENTAL polyp is a rare finding. Only a few cases have been reported, and these have not been diagnosed clinically but have had to await a careful study by the pathologist in order to rule out malignancy. Dorsy[3] reported a case in which the tissue was sent to the third pathologist before a definite diagnosis was obtained. In this case, as well as that reported by Hagstrom,[4] the bleeding was so severe that it threatened the patient's life. This also occurred in the patient being reported in this presentation. A patient reported from the records of the Massachusetts General Hospital[5] had severe hemorrhages but this case was also complicated by an acute and chronic salpingo-oophoritis.

According to Curtis,[1] the designation of "placental polyps" has been given to portions of placental tissue of varying size, which may be retained within the uterus for an indefinite period after an abortion or full-time parturition. If the retention be for a considerable time, the placental tissue still attached to the uterine wall becomes slowly incapsulated by concentric layers of blood and fibrin, forming the polyp tumor. On section, such a tumor will present a central nodule of more or less well-formed chorionic villi, with proliferating chorionic epithelium, covered by layer upon layer of organized blood clot and fibrin, together with round cell infiltration. Portions of trophoblast will serve to prolong the pregnancy reaction of the uterus for an indefinite period. Thus, placental polyps are productive of continuous slight uterine bleeding, and they keep the uterus in a state of subinvolution.

The following description is found in *Principles and Practice of Obstetrics* by DeLee-Greenhill[2]: "If bits of placenta or decidua do not become infected, blood is deposited upon them in successive layers, and a fibrinous or placental polyp results. They cause irregular hemorrhage until they are removed, or they become infected, break down, and are discharged piecemeal with fetid discharge and fever, sometimes with hemorrhage. The polyps may produce sufficient gonadotrophic hormone to give a positive reaction to a pregnancy test."

Report of Case

A forty-year-old woman was admitted to St. Mary's Hospital giving a history of irregular menstruation for one year, but more marked during the last five months. The bleeding had been profuse for two days, and just before entering the hospital she had passed a large amount of blood and clots which, she thought, amounted to nearly a quart.

The past history was of no special significance. She began menstruating at thirteen years of age. Periods were always regular up to one year ago, normal in amount, and caused no discomfort. She had given birth to eight children, all of whom were living and well, and had had one miscarriage three years ago. She had not been conscious of being pregnant since that time. Previous surgery consisted of an appendectomy and a thyroidectomy for a toxic adenoma.

The physical examination revealed a well-developed and poorly nourished woman, very pale. The pulse rate was 90 beats per minute. The temperature was 98.2°. The respirations were 20. The blood pressure was 102 mm. of mercury systolic and 75 mm. diastolic. She appeared older than the chronological age. A mass could be palpated in the midline of the lower abdomen, which was firm and smooth and had the contour of an enlarged uterine fundus. Vaginal examination revealed a normal cervix. The body of the uterus was about four times the normal size, firm in consistency, in good position and freely movable. Erythrocytes numbered 2,880,000, and leukocytes 6,600, per cubic millimeter of blood.

The bleeding subsided shortly after admission. She was transfused and prepared for operation, which was done five days later. Through a lower midline incision, a subtotal hysterectomy was done, and the specimen sent to the pathologist, who reported that there was evidence of malignancy, possibly a chorionepithelioma; so the cervix, fallopian tubes, and ovaries were also removed. For diagnostic purposes, a catheterized specimen of urine was obtained while the patient was still on the operating table. This gave a positive pregnancy test.

The convalescence was uneventful. The wound healed by first intention, and the patient left the hospital on the ninth postoperative day.

Pathologist's Report

Macroscopic.—A uterine fundus which measures 9.5 cm. in length by 7 cm. in transverse and 6.5 cm. in anteroposterior diameter. The specimen weighs 210

Presented before the Duluth Surgical Society.

grams. On being opened, there is a large, sessile nodule attached to the posterior aspect of the endometrium. This nodular mass presents a hemorrhagic, slightly necrotic surface, which is moderately irregular. On section through this mass, it is difficult to note a line of demarcation between the tumor mass and the myometrium. The latter, however, contains numerous large blood vessels. Further sections through this structure show some areas in which the line of demarcation between the tumor and myometrium is demonstrable. The tumor tissue is highly hemorrhagic and in some portions moderately spongy. A few foci of necrosis are present.

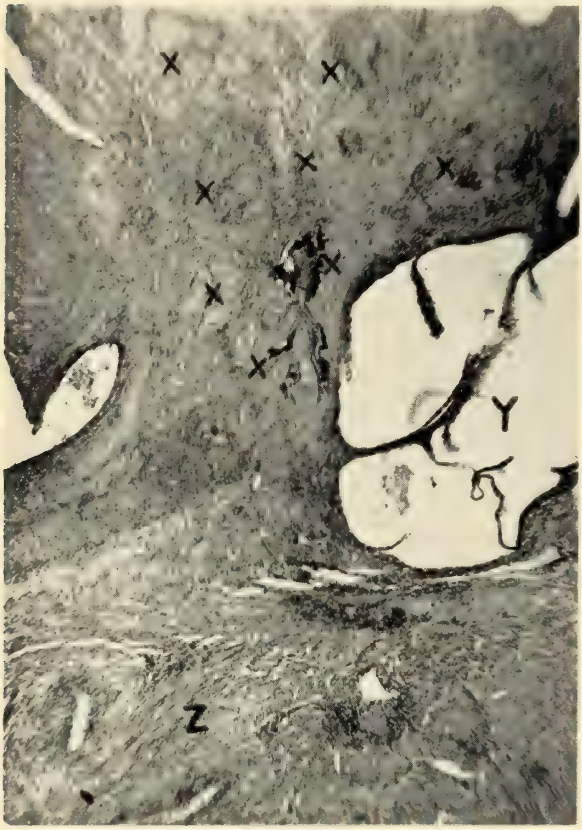

Fig. 1. Low power photomicrograph. (X's) Degenerated chorionic villi enclosed in fibrous connective tissue. (Y) Dilated atropic endometrial glands. (Z) Myometrium.

Microscopic.—Permanent sections of the tumor mass within the uterus show a border of endometrial mucosa which is average in appearance. The mucosa grades into decidual tissue which is moderately fibrous and, in part, hyalinized. There are also localized patches of hyperplasia of the large decidual cells. Along the margin of the tumor mass, there are numerous chorionic villi, some of which contain calcarious foci. Some sections show a moderately diffuse infiltration of mononuclear cells and neutrophils. The chorionic villi do not infiltrate into the muscular tissue of the uterus. In some sections, masses of partially organized decidual tissue separate the villi from the myometrium. A slight amount of trophoblastic proliferation is noted in the myometrium. Otherwise, the latter is not unusual.

Diagnosis.—Placental polyp.

Novak gives the following description: "The gross appearance of the placental polyp, together with its grumous hemorrhagic appearance is not unlike that of the chorionepithelioma, and I know of several instances in which such a diagnosis was made in spite of the total different microscopic structure of the two lesions."

Summary

A placental polyp of the uterus is a rare condition and cannot be differentiated from chorionepithelioma except by microscopic study. Both conditions produce gonadotrophic hormone which can be detected in the urine. A case is presented of a forty-year-old woman whose symptoms and whose pathological tissue, both gross and microscopic, correspond to that of the few reported cases.

EARLY DETECTION OF DISEASE

A little arithmetic convinces one that elaborate annual physical examinations involving complicated procedures and consuming much time of physicians are not the answer to early detection of conditions such as tuberculosis, cardio-vascular disease, cancer, syphilis, and diabetes. The cost is too great and there are not enough physicians.

The answer may lie in multi-phasic rapid screening conducted at the technician level. A number of such experimental programs are now being conducted. In only a few minutes, the person being examined will have a chest x-ray (which may reveal heart abnormalities or lung tumors as well as tuberculosis and certain other lung infections), and a blood specimen will be taken for determination of the blood sugar level and presence of syphilis antibodies. Perhaps other serologic tests will be made. Although physicians will be needed to interpret the tests, the tests themselves will be conducted by technicians.

Such a program will fail completely unless the medical profession is made to understand thoroughly the philosophy of the program, namely, that it does not take the place of the physician in making a diagnosis. In fact, no diagnosis will be made. Only suspected abnormalities will be screened out in this first procedure; the diagnosis will be made later in the physician's office and, it is hoped, at a stage when the physician may be more effective in administering treatment than would have been the case if the patient had waited until the development of full-fledged symptoms forced him to consult a physician.—James E. Perkins, M.D., *Bull. Nat. Tuberc. A.*, January, 1950.

History of Medicine In Minnesota

MEDICINE AND ITS PRACTITIONERS IN OLMSTED COUNTY PRIOR TO 1900

NORA H. GUTHREY
Rochester, Minnesota

(Continued from May issue)

Housen H. Clifton, "cancer doctor," was born in Kentucky in 1830. After the outbreak of the Civil War he enlisted, on August 2, 1862, in Company H of the 72nd Indiana Volunteer Regiment of Infantry and received his discharge on June 26, 1865. In 1866 with his wife Permelia Seeley Clifton and his son William W. Clifton, then eighteen years old, he came to Rochester Township, Olmsted County, and settled on a farm in Section 8, four miles southwest of Rochester on what is still known as the Salem road. Leonard stated that Permelia Clifton also had served her country during the Civil War, as a nurse. In 1887 Dr. Clifton became a member of the local Custer Post of the Grand Army of the Republic, of which for a time he was post surgeon.

What Dr. Clifton's medical training had been is not known; although he treated patients for "la grippe" and other ailments, he concentrated on a domestic remedy, since described as an escharotic agent, for skin cancer. For many years he was called locally the "plaster doctor" or the "cancer doctor." Patients came to him from considerable distances, one at least from Lake Benton, Minnesota. In 1886 recommendations of Dr. Clinton's painless, nonsurgical cancer cure began to appear in the Rochester newspapers and for seven years thereafter there were published also numerous news items about patients he had treated for cancer of the head, face or breast. The most detailed statement, on October 22, 1886, in the *Record and Union,* was as follows:

> Dr. Clifton of Rochester has been for the past sixteen years experimenting on a remedy to cure cancers. He claims to have finally succeeded in producing a remedy that takes out cancers in from seven to fourteen days. All he does is to paint the affected part and the medicine does the work. It does not affect the sound flesh, but destroys the fungus growth of the cancer and it dries up and is easily removed.

Another note, on another subject, was: "Dr. H. Clifton of Rochester has a genuine madstone. Should any one be unfortunate enough to be bitten by a mad dog, the doctor would be glad to let him use the stone."

Housen H. Clifton died suddenly on September 21, 1893, in his sixty-fourth year, from overexertion in fighting a fire which destroyed his home, a few miles from Rochester, on that day. He was buried from the Methodist Episcopal Church of Rochester under the auspices of the Grand Army of the Republic. After his death, his son, William W. Clifton, continued the manufacture and use of the cancer remedy.

William W. Clifton, who was born at Fountain City, Indiana, on December 9, 1848, came to Rochester Township, Olmsted County, in 1866 with his parents, Housen H. Clifton, farmer and medical practitioner, and Permelia Seeley Clifton. Leonard stated that William Clifton became an ordained minister of the Methodist Episcopal Church but never followed the calling; that he studied medicine under his father and at the Metropolitan School of Physicians and Surgeons (Metropolitan Medical College, Chicago?), from which he was graduated; that he was a Republican "with a strong leaning to prohibition and other reforms tending toward the general good of the country." After his father's death he succeeded to the practice in treatment for skin cancers, as noted, and until the early nineteen hundreds his card appeared in Rochester newspapers: "Cancers cured without cutting. Dr. Clifton's Celebrated Cure. Call on the doctor. W. W. Clifton, Rochester, Minnesota." Subsequently, it is said, he became a veterinarian.

William W. Clifton was married to Miss Alti Wagoner, daughter of respected pioneer settlers who came to New Haven Township in 1856; one of Mrs. Clifton's brothers, Joseph H. Wagoner, was for many years a successful dealer in organs and pianos in Rochester. Dr. and Mrs. Clifton had four children, Nettie, Walter, George and Sadie. Nettie G. Clifton, a graduate of Hamline University, was a teacher in the public schools of Minnesota and North Dakota. She was married, in September, 1902, at the home of her parents, on the old Clifton homestead, to Professor Earl G. Berich, a biologist, of Fargo.

Alexander Brodie Cochrane, graduate of the Minnesota College Hospital on March 24, 1882, came to Rochester, Minnesota, on August 1, 1883, as assistant physician to Dr. J. E. Bowers at the Second Minnesota Hospital for Insane. He was the third physician to be appointed to the hospital staff and was successor to Dr. W. A. Vincent, who in 1881 came as the first junior physician appointed in the institution. On October 11, 1883, under the new state law to regulate medical practice, Dr. Cochrane received certificate No. 46 (R).

Dr. Cochrane's musical ability added to his value as physician: The hospital choir, made up of employes and patients, under the direction of Dr. Cochrane as organist, furnished the music at special services and holiday celebrations. His name has not appeared in connection with a local medical society, for the reason that the Olmsted County Medical Society, inactive at that time, was not reorganized until December, 1885, after Dr. Cochrane had gone. In newspaper accounts Dr. Cochrane was mentioned as one of an operating team, with Dr. J. E. Bowers, who assisted Dr. W. W. Mayo in removal of ovarian tumors.

Dr. Cochrane resigned his position as assistant physician early in December, 1884, and on December 10, after a week's visit with friends in Chicago, he sailed for "his old home in England." He was succeeded at the state hospital by Dr. Homer Collins.

E. G. Cole, professedly a skillful oculist, came to Rochester, Minnesota, early in 1862 for the purpose, he said, of restoring "the blind to sight," no cure, no pay, and remained probably several months. His headquarters were at J. S. Woodard's drugstore. The chief note concerning him was under "Common Council Proceedings" in the *Rochester Republican:* Dr. Cole's bill for services to a certain indigent patient on whose eyelid he had operated, was taken up for reconsideration and it was decided to appropriate fifteen dollars, to be paid when cure should have been effected. Dr. Cole's professional cards in the local newspapers were typical of the notices used by the numerous traveling medical fraternity of the time.

J. C. Cole (1813-1890), an honorable and benevolent man, was the first physician, surgeon and druggist of the village of Marion, Marion Township, Olmsted County, and was in active practice there from 1856 into 1866, under the rigorous conditions of pioneer life.

Born in Butternuts, Otsego County, New York, on January 5, 1813, J. C. Cole was a son of Mr. and Mrs. Richard Cole, who were the parents of nine children, eight sons and a daughter. In 1836 J. C. Cole traveled west to Illinois, where he spent twelve years before removing to Wisconsin. At Plainfield, Will County, Illinois, he was married on September 7, 1848, to Mary Ruth Dupuy; of this marriage there were three children, William, Mary and Helen. Mrs. Cole died on December 10, 1852, and Helen on the following day, both at the family home in Rosendale, Fond du Lac County, Wisconsin. Two years later Dr. Cole traveled from his Wisconsin home to Butternuts, New York, where on January 18, 1854, he was married to Mrs. Almira E. Safford. Of the second marriage there was one child, C. J. Cole.

Dr. Cole first arrived in Marion, Minnesota, on April 11, 1856. After taking up a government claim, he went back to Wisconsin for his family and returned with them one month later. To the settlement, which then comprised a small tavern, a store, a scattering of cabins and the groundwork of a schoolhouse he added a new residence and a drugstore. For a few months in 1863 Dr. Cole had an office on Broadway in Rochester, for the practice of medicine, it was announced, on the most scientific principles of the day. A newspaper note of 1860 indicates that he made an occasional trip east for professional study.

In 1866 there occurred the first of many attacks of the nervous and mental disturbance that made Dr. Cole's hospitalization necessary at intervals the remainder of his life. He died in Minneapolis on January 6, 1890, survived by three children, Mary and William, and C. J. Cole, of Marion, and was buried at Marion; his funeral services were conducted by the Reverend Frank Doran, of Rochester. Mrs. Cole had died in Marion on December 6, 1872.

Two of Dr. Cole's brothers were early settlers in Minnesota: B. M. Cole, of Pleasant Grove, and Dr. G. H. Cole, a dentist of Marion and sometimes of Rochester, from 1859 to 1866. Later Dr. G. H. Cole practiced dentistry in Owatonna, Winnebago City and, after 1882, in Mankato. He was born on May 24, 1832, at Butternuts, New York; was married on April 17, 1861, to Clementine E. Rossman of Rochester; served in Company D of Brackett's Battalion of Cavalry during the Civil War, from January 5, 1864, until he was mustered out in March, 1865, as sergeant, because of disability. He died in Mankato on January 1, 1885.

Homer Collins (1859-1949) was the fourth appointee, the third to serve as the assistant physician on the staff of the Second Minnesota Hospital for Insane at Rochester, succeeding Dr. Alexander Brodie Cochrane late in 1884.

The son of Nelson and Isabella Collins, Homer Collins was born in 1859 in Perinton Township, Monroe County, New York, just ouside the little city of Fairport. Orphaned by the death of his mother when he was a month old and the death of his father less than a year later, he was brought up by his paternal grandfather and two aunts, sisters of Nelson Collins.

He received his early education in the public schools of Rochester, New York, and his academic courses at the Rochester Free Academy and at Cornell University; from Cornell he was graduated in "natural history," and received the cash prize awarded in the department of Dr. Law. In 1882 he entered the College of Physicians and Surgeons of Columbia University, from which he was graduated in 1884 with the degree of doctor of medicine. After taking his degree, he held a service of several months at the Presbyterian Hospital of New York; attended lectures at the New York Eye and Ear Infirmary, and at the New York Ophthalmic and Aural Institute (after 1913 the Hermann Knapp Memorial Eye Hospital), under the instruction of Dr. Herman Knapp, one of New York's great ophthalmologists and otologists; and took several courses of lectures at the New York Post-Graduate Medical School.

On December 1, 1884, Dr. Collins began his work at the state hospital in Rochester, Minnesota. The physicians of the hospital were an important part of the city and Dr. Collins was no exception. He made many friends and commanded the respect of fellow physicians. On occasion he was one of a varying group, which often included Dr. J. E. Bowers, superintendent of the state hospital, who assisted Dr. W. W. Mayo in performing surgical operations of special interest.

Dr. Collins was a charter member of the Olmsted County Medical Society when it was reorganized in December, 1885, and he became a member of the Minnesota State Medical Society. On April 15, 1887, he received his state license No. 1359 (R) to practice in Minnesota. When he resigned his position at the state hospital in October, 1889, to enter private practice, he was honored by the officials and the attendants, who presented him with a diamond ring and a gold-headed cane. On leaving Rochester, Dr. Collins returned to Rochester, New York, with the idea of entering practice there, but by the early autumn of 1890 he had decided on the Middle West, and after considering Superior, Wisconsin, as a location he settled in Duluth.

In June, 1895, Homer Collins was married to N. Gertrude Sloan of Duluth. Dr. and Mrs. Collins had four children, a son, Homer Collins, Jr., and three daughters, Cordelia, Gertrude and Patricia, all of whom, in 1945, were living in Duluth. Of the four grandchildren, one was in service in the United States Army Air Forces during World War II. (Dr. Collins died on July 31, 1949, at the Duluth Hospital, aged ninety years.)

Discussion of Dr. Collins' long and distinguished professional career in the special fields of ophthalmology, otology, rhinology and laryngology belongs primarily to the history of medicine in Duluth and St. Louis County.

Franklin Judson Cressy, born in 1849, was the son of Mr. and Mrs. F. C. Cressy, who long were respected residents of Olmsted County.

Details of Dr. Cressy's early life and education are lacking. On September 2, 1910, however, he was referred to by the *Olmsted County Democrat* as an "old time resident of Rochester and a grade school pupil here in the Central School the first year it was opened" (1868). He received the degree of doctor of medicine from the College of Physicians and Surgeons of Keokuk, Iowa, in 1877. Earlier, in April, 1876, the *Rochester Post* had referred to him as Dr. Cressy and cited a case in which he had given aid. In March, 1877, this newspaper commented as follows: "The Howard Lake, Stearns County, Minnesota, paper says that Dr. F. J. Cressy, formerly of this city, has entered into partnership with Dr. Knowles of that village for the practice of his profession. Dr. Cressy is a young man of superior qualification and good character and we wish him much success in his new field of endeavor."

Well before 1890 Dr. Cressy was established in practice at Granite Falls, Yellow Medicine County. His state license, No. 581 (R), was issued on December 31, 1883. He was a member of medical societies, county, state and national; his name appeared in the directory of the American Medical Association from 1906 to 1918, inclusive.

W. J. Conan, physician and surgeon, came from Fond du Lac, Wisconsin, to Rochester, Minnesota, in January, 1879, and for about five months, as indicated by his professional card published in the *Rochester Post,* practiced medicine in the city. His office, advertised as open night and day, was over a millinery store, in H. A. Brown's block, on Broadway.

Edwin Childs Cross (1824-1894), one of the earliest and best educated of the pioneer physicians and surgeons of Olmsted County, came in May, 1858, from Brattleboro, Windham County, Vermont, to Rochester, Minnesota, which then was a frontier settlement. His younger brother, Dr. Elisha Wild Cross, had visited Rochester two years earlier and on his return east had described the growing community and its need for physicians. There were in Rochester in 1858 a few inactive practitioners, Dr. M. T. Perrine, the earliest, Dr. L. H. Kelley, Dr. J. N. McLane and Dr. C. S. Younglove, and Dr. I. H. Bardwell, who in 1859 removed to Pleasant Grove. By 1860 Dr. Cross was so well established that he sent for his brother to join him in practice. Although there was a difference of only four years in their ages, Dr. Cross was always called "Old Dr. Cross," and Dr. Elisha, "Young Dr. Cross." The partnership was interrupted in December, 1861, when Dr. E. W. Cross became a surgeon in the Union Army. In later years, it is said, although the brothers consulted each other professionally and part of the time shared offices, in the main they practiced independently.

Edwin C. Cross, born on April 6, 1824, at Bradford, Vermont, was the eldest living child of Peter Cross (1785-1858), farmer and well borer, and his second wife, Dorcas Wild Cross (1797-1839), both of English descent and early settlers in New Hampshire. Peter Cross was the son of Stephen Cross and Margaret Bowen Cross, both of whom were born in the United States. The sisters and brothers of Edwin C. Cross, all of whom, in 1946, were long since dead, were: Abigail W., Elisha Wild, Amos E. (died in Rochester in 1866), Sarah G. (Mrs. Ed. Elliott, of Rochester), Henry and Mary L. Cross. By the first marriage of Peter Cross there were the following half brothers and half sisters: John G., Caroline M., Michael C. M., Dolly G. and Elbridge O. Cross.

At the age of fourteen years Edwin C. Cross decided to become a physician, and in the next eight years, earning his way, he acquired an education, academic and scientific. After early years in common schools and at Bradford Academy, he finished his classical course at Dartmouth College; later, after completing a year's study under Dr. John Poole, of Bradford, an alumnus of the medical department of Dartmouth, he returned to the college to begin his formal medical course. There are in the possession of Miss Louise Cross, granddaughter of Dr. Cross, his cards of admission, in 1844, to classes in surgery, obstetrics, anatomy and physiology, on the recommendation of the New Hampshire Medical Society. Subsequently he attended lectures at Castleton Medical College, in Castleton, Vermont, at the Vermont Medical College, in Woodstock, and at the "College of Physicians and Surgeons" (College of Medicine and Surgery?), in Philadelphia. In 1846 he was graduated in medicine from Norwich University, in Norwich, Vermont.

Dr. Cross had an initial practice of four years in Leyden, Massachusetts, was three years in Guilford, Vermont, and nearly four years in Brattleboro. He was married on October 1, 1849, at Charlemont, Massachusetts, to Fanny E. Marcy, who was born at Coleraine, Massachusetts, on August 15, 1827. Fanny Marcy was a teacher of French at Mount Holyoke Female Seminary (after 1893 Mount Holyoke College), and was the youngest of a family of eleven children, many of whom distinguished themselves in the fields of letters, theology and science; her brother, Oliver Marcy, LL.D., in the late eighteen seventies was acting president of Northwestern University. Dr. and Mrs. Cross, after the death of their first child and, a few weeks later, loss of their home by fire, set out early in 1858 for Minnesota.

For thirty-four years in Rochester, Olmsted County, Dr. Cross, cultured, progressive, of many interests, was an influential physician and citizen. Tall, heavy and muscular, he was dark-complexioned, had black hair, heavy brows over deep-set eyes, and wore a mustache and chin whiskers. Handsome and dignified as a young man, in later decades he was bowed and rugged, of stern appearance, and of sterner manner which, however, belied his heart. Dr. W. J. Mayo once said of him, "The Old Doctor certainly had a stern exterior, but I have seen him hand a man who was out of luck a thousand dollars and say, 'Here, start over again'." His patients relied on him, his family were devoted to him.

Although, as his grandson has said, he came to the new country "with his two hands, and for professional aids a few surgical instruments, quinine, chloroform, laudanum or opium, castor oil, and whiskey for a heart stimulant," he soon achieved well-earned and increasing prosperity. Practicing in an era marked by inconvenience and hardship, Dr. Cross in saddle, wheeled vehicle, or sleigh, as season demanded, made the long laborious trips throughout the countryside that his extensive practice called for, and gave aid in all the illnesses and accidents peculiar to the times and region. Venerable citizens in various communities have recalled of him and his brother, "The Crosses did all the doctoring in our neighborhood." In emergency he was quick and resourceful, in daily general practice his methods of treatment were perhaps less drastic than those of some of his colleagues.

In his earliest years in the county there were yet Indians of dubious friendliness in the community. Dr. Cross had no fear of sober Indians because they knew and respected him as a "medicine man," but for possible defense against drunken Indians of clouded judgment he carried on saddle or in rig a sawed-off, muzzle-loading, single-shot rifle. In later years he used the gun to shoot fish in the Zumbro River; there was so much metal between the bore and the periphery that he could fire the gun with its barrel under water without danger of its exploding.

Educated as a member of the regular profession in conservative schools, Dr. Cross while in the East became interested in homeopathy, and when he arrived in Rochester he announced himself through the local press as a homeopathic and hydropathic physician and surgeon. For several years after 1860, part of the time in partnership with his brother, he had the Rochester Infirmary, which served as his headquarters, and there made available the homeopathic pharmacopoeia and a variety of soft water baths. By 1867 he had returned to the regular school.

Dr. Cross had a long and honorable record in official medical organizations. A founder of the early Olmsted County Medical Society on April 15, 1868, he was prominent in its activities, and when, on December 4, 1885, the society was reorganized formally, he was a charter member. On June 16, 1869, he became a member of the Minnesota State Medical Society, soon after its reorganization, and well into the eighteen eighties he was a faithful worker, as correspondent, member of committees, and delegate to meetings of the American Medical Association. His Minnesota state certificate to practice, No. 905 (R), was issued on May 9, 1884.

When Dr. Cross arrived in Rochester in 1858, existing conditions of health and sanitation in the city left much to be desired. Presently the newspapers began to print graphic descriptions of straying livestock, muddy, slimy streets, alleys blocked with refuse, and of polluted wells. In 1864 Dr. Cross became a member of the local board of health and served on it, often as chairman, for more than twenty years. After 1872, in co-operation with the state board of health, he gave detailed reports on outbreaks of disease in surrounding rural districts, and during the smallpox epidemic of 1876-1878 acted as an official vaccinator.

A student of medicine and allied sciences as well as of literature, Dr. Cross possessed a fine library and subscribed to the current medical journals, which he read faithfully. Frequently he was out of town for several days on a series of professional calls in the country,—word would be left at one place for him to come on to another,—and on his return home there would often be awaiting him an accumulation of new medical literature. In order to keep himself up-to-date, it was the doctor's custom on such occasion to retire to his room with books and journals, a pitcher of milk and a plate of bread, and by the light of a student lamp at his bedside, to read all night. As a preceptor he contributed to medical education. Perhaps the first medical student to come under his instruction was his brother Elisha, whose education he sponsored and directed in the late forties in Massachusetts and Vermont. In Rochester, among the young men who studied under him and his brother were Sylvester L. Bedal, from Eyota, Edwin D. Stoddard, of the vicinity of Rochester, and William A. Vincent, an easterner, later of Iowa.

Although Dr. Cross did not seek civic office, and on one occasion declined the nomination for mayor of Rochester, he was active in movements for public welfare. When the Olmsted County Volunteers were organized at the beginning of the Civil War, he was delegated to tender the services of the company to the governor of the state; and in the offices of the Drs. Cross were held organizational meetings of Sanborn's Guards (Oronoco Home Guards). Dr. E. C. Cross was one of the first examiners appointed when, in 1862, the United States Bureau of Pensions was instituted in Minnesota. In March, 1865, he succeeded Dr. W. W. Mayo as surgeon on the Board of Enrollment of the First Congressional District. It is told of Dr. Cross that he was clever in detecting malingerers, especially those who pretended to be deaf. He would listen sympathetically and would seem to be convinced. As such an applicant for exemption was turning to leave the office, Dr. Cross would ring a silver half dollar down onto the floor; two thirds of the "deaf" applicants on whom this device was tried whirled at the sound. In later years Dr. Cross was medical examiner of candidates for training at the United States Military Academy at West Point, was often called as expert witness in medico-legal cases, and was examiner of persons up for commitment to the state hospital for insane at St. Peter and, after 1879, at Rochester.

He was interested in city real estate to the extent, in 1869, of improving a section of northeast Rochester with a group of new cottages, and, in 1878, together with leading business men, of building a large brick block on Broadway in which he and his brother had offices. His chief hobby, however, was a fine farm, "Chesterland," near Chester in Marion Township, stocked with high-grade cattle, where he perfected a model dairy, a rare enterprise in that time. He was influential in organizations for the furtherance of improved agriculture, horticulture, dairying and buttermaking. In 1882, when he welcomed a convention of the Butter and Cheese Association, at its first annual meeting, he gave a keen analysis of farming, dairying and stockraising in the region; he stressed the importance of converting grain farms into livestock farms, and expressed the belief that the time was at hand when many of the grain elevators on the line of the railroads must give place to stock yards, and that cattle cars must become more common on the great lines of transportation from the Northwest. Dr. Cross brought in from Kentucky fine shorthorn beef cattle, raised improved strains of sheep, bred beautiful Morgan horses as well as horses from famous racing and trotting stock, one of which was the well-remembered Ada Wilkes. He did not race his horses, but privately he tried to beat the track record and often did; when in 1887 he bought from Eleazer Damon, pioneer jeweler, a stop watch for $170, a local newspaper reported the purchase and stated, "A stop watch is getting to be a necessity for all the breeders of fast horses in the city." (In 1947 this watch, still in the possession of the family, was in good condition.) Dr. Cross's sulky was a familiar sight about Rochester, as were his carriages and, in winter, his cutter and his handsome double-seated sleigh generously equipped with buffalo robes. It is said that he brought into the county the first Gordon setters seen here and that Irish setters were another of his favorite canine breeds. One Irish setter, Denny, he trained to ride with him in winter, the dog usually lying across the doctor's feet as a footwarmer, but sometimes taking a turn as driver; on signal Denny would sit with his head resting on the doctor's knee; Dr. Cross would arrange the lines and place them in the dog's mouth, and Denny would hold them firmly while the doctor took time out to warm his hands.

Dr. Cross and his brother in the seventies were among the founders of the Sportsman's Club and the Rifle Club of Rochester. And when the Marrowfats and the Stringbeans, social groups of business and professional men, were organized for the formation of baseball teams that were friendly rivals, the Drs. Cross, each weighing more than 200 pounds, qualified for the Marrowfats.

Dr. Cross was a Republican, a supporting member of the Universalist Church, an early member of the Masonic Lodge in Rochester (once Worshipful Master), holder of the Thirty-second Degree of Masonry, and an officer in the Grand Commandery of Knights Templar. He traveled extensively, combining clinical visits and attendance at medical conventions with conclaves of fraternal organizations.

On the morning of July 4, 1894, occurred the tragic accident that ended the life of this outstanding physician and citizen. Dr. Cross was driving a team of spirited young horses on Main Street and as he neared the southern end of the street he passed some boys who were out to celebrate the Fourth. The boys waited until the team had gone a half block or more before they threw some lighted firecrackers into the road, but the horses heard the explosion and started to run. Dr. Cross succeeded in quieting the horses and pulling them to a dead stop, when at another explosion they lunged and both of the bits broke. In those days Main Street curved to the left at the southern end where a road came in from the right. While trying to guide the running horses to the left, Dr. Cross attempted to swerve them slightly to the right to avoid a pedestrian; the horses swung sharply right, the buggy struck a large tree, throwing the doctor out against a board sidewalk that stood eight or ten inches high, and on into a picket fence that paralleled the walk. Although his injuries were mortal, severe cuts about the head, broken ribs, a shattered femur and a mangled thigh, Dr. Cross remained conscious to the end of his life and told his family the details of the accident. He died on the evening of July 5, 1894. At his funeral services Rochester, and the Olmsted County Medical Society as a group, paid him tribute.

Edwin Childs Cross was survived by his wife, Fanny Marcy Cross, and by three children: Anna Dorcas (1860-1937), Mary Almira (Mrs. Fred. C.) Van Dusen (1863-1938), and John Albert Grosvenor Cross (1870-1928). Three sons had died young: Edwin (1855-1857, Frank Dean (1857-1866) and Edward (1868-1869). The death of Mrs. Cross occurred on September 21, 1901. In 1946 there were living twenty-five descendants of Dr. and Mrs. E. C. Cross.

Elisha Wild Cross (1828-1899), younger brother of Edwin Childs Cross, came to Rochester, Minnesota, as a visitor in 1856 and as a resident in April, 1860, when he joined his brother in the practice of medicine and surgery. It was then that he received the title "Young Dr. Cross," by which he thereafter was distinguished.

Born at Bradford, Vermont, on January 31, 1828, Elisha W. Cross obtained his early education at Bradford Academy and at the Wesleyan Seminary at Wilbraham, Massachusetts. His first medical training he received under his brother's preceptorship, and subsequently he took medical courses at the Castleton Medical College, in Castleton, Vermont, and at the Vermont Medical College, in Woodstock, from the latter of which he was graduated with the degree of doctor of medicine in 1851. In that year he began a five years' medical practice in Reedsborough, Vermont, after which he practiced in Guildford Center, Vermont, until he came with his wife and two children to Rochester. He was married on October 5, 1849, at Bradford, Vermont, to Martha Peckett, who was born in that village on June 24, 1829.

In December, 1861, Dr. Cross was appointed Assistant Surgeon of the Fourth Regiment of Minnesota Veteran Volunteers in the Union Army; on August 9, 1863, he was promoted to major and surgeon and so served until he resigned, because of impaired health, on December 22, 1864. Throughout his service, which took him into famous battles, among them Iuka, Vicksburg, Chattanooga, Lookout Mountain and Altoona, and on Sherman's march to the sea, his record was one of efficiency and skill enhanced by kindness to the sick and wounded and won him their gratitude and affection.

Beginning early in 1866, Dr. Cross, although in close association with his brother, Dr. E. C. Cross, practiced independently of him. For a time Dr. E. W. Cross had his office at his residence on East Fifth Street (East Center Street). His was the heavy general practice, in town and country, of pioneer times. There is record that in the seventies he and Dr. W. W. Mayo together performed various major surgical operations and that in December, 1876, they entered partnership, sharing three offices over Geisinger and Newton's Drugstore on Broadway. This association ended in June, 1878.

Dr. E. W. Cross, like his brother, was tall, dark and strongly built; Dr. Elisha wore a mustache, minus the chin whiskers that his brother affected, and in later years, as ill health forced him into inactivity, he became corpulent. Although each brother had his special bent, the careers of the two, in profession, avocations and recreations, were parallel. "Young Dr. Cross" was a Mason, a member of the Knights of Honor and of other fraternal organizations and of the Military Order of the Loyal Legion of the United States, a supporting member of the Universalist Church, an agriculturist, a founder of the Minnesota Horticultural Society, and a raiser of fine horses and cattle on his large farm "Heathiola" near Chester. Active in all that went to improve the city of Rochester, he was once commissioner at large, long a school commissioner and for many years president of the board of education. For even longer he was the able president of the Rochester National Bank and a director of the Union National Bank.

(To be continued in the July issue.)

President's Letter

DR. POTTS WOULD BE SURPRISED

The excellence of Minnesota medical conventions is an established fact. We look forward to the sessions each year, well aware on the basis of past experience that we will attend stimulating scientific meetings and round-table discussions, that we will be renewing friendships with colleagues that we see, perhaps, only on this once-yearly basis, that we will have an opportunity to view scientific and commercial exhibits of great interest and value.

The 1950 convention was no exception. For myself, and I think I speak for all the physicians who attended, it was an outstanding conference.

But Dr. Thomas Potts would have been surprised if he had been there.

For him, the 1950 convention would have been amazing, far beyond the reach of his imagination when, in 1853, he and nineteen other pioneer Minnesota physicians held the first and organizational convention of the Minnesota State Medical Association.

This little band of professional men that, today, would represent, numerically, only one of our round-table discussion groups, has given us a great heritage—one of the most tangible evidences of which is the annual convention, where learning and recreation are balanced to prepare and refresh us for the arduous professional duties that the coming year brings.

It was a pleasure for Duluth physicians to be hosts to so many of our friends from all over the state and to feel that our efforts, in a small way, helped to carry on the noble traditions established by Dr. Potts and his fellow practitioners nearly a century ago.

F. J. Elias.

THE VDRL TEST FOR SYPHILIS

BEGINNING July 1, 1950, the laboratory of the Minnesota Department of Health will report the quantitative VDRL blood and spinal fluid tests for syphilis. The articles by Drs. Kimball and Bauer and by Dr. Lynch explaining the laboratory and clinical aspects of this new serological test appear in this issue. Physicians would do well to read both articles in order to be able to correctly evaluate the new serologic report.

Although there are advantages to the quantitative reporting of the positivity of the VDRL test, it does not follow that the height of the titre correlates with the clinical activity of the disease. On the other hand, the higher the titre, the stronger the serological evidence is for supporting the diagnosis of syphilis. Further, the height of the titre gives no indication of the likelihood of a positive spinal fluid or a paretic curve in the colloidal gold test.

The desirability of a repetition of the test before a diagnosis of syphilis is made still holds. Other factors, such as the presence of infections mononucleosis and smallpox vaccination, may produce false positives. When the serological test is questionable, two full vials of blood should be submitted in order that all the tests may be run. As the new test requires more blood, one would be playing safe in submitting a full vial on each occasion.

INDUSTRIAL COMMISSION REPORTS

OUR ATTENTION has been called by the Industrial Commission of Minnesota to the fact that while most physicians comply with the law in the matter of reporting workmen's compensation cases to the Commission promptly when so requested by the Commission, a few do not. These reports are necessary in order that the injured employe may receive the quick and speedy remedy by way of compensation and other benefits provided by statute. Such offending physicians are not only doing an injustice to their patients, but they are also violating the laws of the State of Minnesota and are subject to a civil penalty of $50.00 for each such failure to report.

The law as it applies to the reporting of Workmen's Compensation Cases to the Industrial Commission is reproduced verbatim below. It is the wish of the Minnesota State Medical Association and the Minnesota State Board of Medical Examiners to co-operate with the Industrial Commission of Minnesota in having physicians make these reports as provided by law. The Industrial Commission has been requested to furnish the names and addresses of physicians who are repeatedly in violation of the law referred to, to the Minnesota State Board of Medical Examiners for disciplinary action such as is used for failure to comply with the laws of the State regarding the reporting of births and deaths.

The Industrial Commission seeks first of all the co-operation of *all* the physicians in the State in this matter. If the report is not forthcoming, the names of the offenders will be referred to the Minnesota State Board of Medical Examiners for disciplinary action.

DUTY OF PHYSICIANS IN REPORTING WORKMEN'S COMPENSATION CASES TO THE INDUSTRIAL COMMISSION OF MINNESOTA

"Section 176.32 * * * Every physician or surgeon who shall examine, treat, or have special knowledge of, any injury to any employe compensable under this chapter, shall, within ten days after receipt of any request therefor in writing made by the industrial commission, report to the commission all facts within his knowledge relative to the nature and extent of any such injury and the extent of any disability resulting therefrom, upon a form to be prescribed by the commission.

It is hereby made the duty of the commission, from time to time and as often as may be necessary, to keep itself fully informed as to the nature and extent of any injury to any employe compensable under this chapter, and the extent of any disability resulting therefrom, and the rights of such employe to compensation; to request in writing and procure from any physician or surgeon examining, treating, or having special knowledge of any such injury, a report of the facts within his knowledge relative thereto.

Any employer or physician or surgeon who shall fail to make any report required by this section, in the manner and within the time herein specified, shall be liable to the State of Minnesota for a penalty of

$50.00 for each such failure, and such penalty shall be recovered in a civil action brought in the name of the state by the attorney general in any court having jurisdiction thereof, and it shall be the duty of the commission when any such failure to report occurs to immediately certify the fact thereof to the attorney general, and upon receipt of any such certification the attorney general shall forthwith commence and prosecute such action. All penalties recovered by the state hereunder shall be paid into the state treasury.

No such report or part thereof, nor any copy of the same or part thereof, shall be open to the public, nor shall any of the contents thereof be disclosed in any manner by any official or clerk or other employe or person having access thereto, but the same may be used upon the hearings under this chapter or for state investigations and for statistics only, and any such disclosure is hereby declared to be a misdemeanor and punishable as such.

For the purpose of determining the merits of a compensation claim the commission may permit examination of its file in a compensation case by an attorney at law upon the furnishing to the commission written authorization therefor, signed by the employe, his dependent or dependents, the employer or insurer, as the case may be.

Any employer or insurer or injured employe shall, upon request of the commission, file with the commission all medical reports in the possession of such employer or insurer having any bearing upon the case or showing the nature and extent of disability; provided, that duly certified copies of such reports may be filed with the commission in lieu of the originals."

Section 176.32 Minnesota Statutes for 1945.

GEORGE E. FAHR

On June 15, 1950, Dr. George E. Fahr is retiring from the Medical Staff of the University of Minnesota Medical School. For years he has been in charge of the Medical Department at the Minneapolis General Hospital, and the great demand for a residency in his department attests to his ability as a teacher. In his knowledge of the heart and electrocardiography, Dr. Fahr has no peer. He was associated with Dr. Einthoven at the University of Leyden in developing the first electrocardiograph, and the first electrocardiogram taken in this country was taken by Dr. Fahr on his father. Through the years, Dr. Fahr has kept a buoyancy and enthusiasm that is the desire of all medical men. In the future, he plans to do medical consultation in private practice, the Veteran Hospital and also in the Minnesota medical care program with Dr. Ralph Rossen.

In years past, retirement from a teaching post meant the word in its literal sense. Now, such retirement means freedom from administrative responsibilities, time to engage in research, and sharing more fully clinical experience and judgment. We know Dr. Fahr plans to retire in this sense.

THE SAME GUY PAYS

One curse of the Welfare State is the illusion it creates that the people are getting something for nothing.

Take Britain's National Health Service. It was much advertised as the "free" health plan. The British people were to be able to visit the doctor, the dentist, or the wig maker and have their needs cared for without paying anything except a nominal "insurance" premium.

Obviously these payless visits had to be paid by someone but the complications of a 1950 model government budget often obscure where the money comes from Budget developments in Britain the past couple of weeks however, shed some light on how these "free" services are financed.

On April 18 Chancellor of the Exchequer Cripps presented to the House of Commons the government's budget for the year which began April 1. The major item of increased spending was for socialized medicine. The amount of that increase was about $363 million, bringing the total to approximately $1 billion for the new fiscal year.

To keep revenues up with expenses, Sir Stafford proposed among other things that the gasoline tax be raised to 20 cents a gallon, from 10 cents, and that a 33⅓ per cent levy be imposed on the sale of trucks.

Much of the burden of those taxes would fall on truck operators. So the beneficiary of health service might say: "That's fine, let the truck owner pay for it."

But it doesn't work that way, as our Mr. Evans reported in this newspaper's "London Cable" yesterday. He says: "The butcher, the baker and the highway freighter are all racing to shift new transport costs to the consumer. They contend they have no other choice after Chancellor of the Exchequer Cripps' double-barreled budget attack on road travel—a 100 per cent increase in the gasoline tax and a new 33⅓ per cent purchase (sales) tax on commercial vehicles."

Meat traders want to impose an extra delivery charge a subterfuge for a rise in the price of meat which is government-controlled. Green grocers are ready to raise their prices. Fruit and potato men talk of a 10 per cent price rise. Bakers are stirred up, too.

So the higher cost of "free" medicine will go right on the consumer's grocer bill. He may not have to pay the doctor, but he pays, just the same.—Editorial, *Wall Street Journal,* May 2, 1950.

MEDICAL ECONOMICS

Edited by the Committee on Medical Economics
of the
Minnesota State Medical Association
George Earl, M.D., Chairman

POLLS SHOW OPPOSITION TO SOCIALIZED MEDICINE

There is mounting evidence that the public nderstands the dangers in a scheme of govern- ent medicine. The Washington office of the merican Medical Association reports that over- helming public opposition to compulsory health surance has been registered in three polls con- ucted by Representatives.

Representative J. Harry McGregor of Ohio. mpling his district on this and other subjects, ound that only 10 per cent of the people wanted ocialized medicine. The vital question which Mr. IcGregor asked on his questionnaire was, "Do ou favor any type of federal legislation placing e medical and dental profession and operation f our hospitals under Federal control?" The ashington office reports the results:

> "Two thousand replies were received. Mr. McGregor does not give the numerical totals but lists the replies as ten per cent yes, 90 per cent no. A breakdown by professions shows *opposition from 99 per cent of the businessmen, salesmen, professional and retired people.* Next in line in opposition were housewives, 98 per cent opposed; farmers 97 per cent, and attorneys and barbers 96 per cent. Socialized medicine had its strongest support among school teachers, 12 per cent of whom answered yes."

Representative Thomas E. Martin of Iowa ade a similar survey which showed only about 4 per cent in favor of compulsory health insur- ice. Sending out approximately 25,000 ques- onnaires, Mr. Martin received 4,221 replies, hich is regarded as a reliable sample.

Included in the eighteen questions asked, was is: "Do you favor socialized medicine?" Re- onses totaled overwhelmingly against—3,409 no nd 575 yes. It is significant that the districts mpled are almost evenly divided between rural nd urban residents.

Representative Henry J. Latham of New York included two important questions in his inquiry: (1) Do you favor socialized medicine? and (2) Do you favor a national health program which would not socialize health services but would supply Federal grants and aids to the States and communities for health purposes? Mr. Latham sent out 95,000 questionnaires and has received 20,000 back, but only 5,000 have been tabulated thus far. In Queens district, only 13 per cent (753 persons) answered yes to the first question; 4,424 said no. The second question brought a more evenly divided answer: 3,009 said yes and 2,136 answered no.

Seeking their constituents' opinion on the matter shows that these representatives are among those actively concerned over this administration measure.

The narrow margin by which the British socialists won the election in February was triumphantly dubbed a "victory" and a "mandate from the people." If such a narrow margin is a mandate, these polls, showing such a large margin against compulsory health insurance, furnish these legislators with a mandate far more significant than any claimed by the British socialists.

MEDICINE CONTINUES TO THRIVE ON TRUTH

The Journal of the Oklahoma State Medical Association recently made an observation on the perennial threat against the advances made by medicine. Under the title, "Medicine Perennially Under Fire," the publication comments:

> "All this agitation about medicine is nothing new. It runs throughout the ages: from 1950 B.C. in Mesopotamia, to 1950 Washington, D. C.; from the shifting sands of the Euphrates to the grass clad shores of the Potomac; from Nebuchadnezzar to President Truman; from Hippocrates, the father of medicine, to Oscar R. Ewing, who . . . wants to be father of us all, thus giving every doctor an oath.
>
> "Through it all there has never been any excuse

> for the medical profession to depart from the truth. Even political pressure can be met with nothing as effective as the plain truth about medicine's unfailing service to humanity. It has weathered the rise and fall of all governments and all civilizations. If left alone it will help save and stabilize our own; if subjected to the rule of bureaucracy it will witness the inevitable decline and yet survive to help build another civilization according its wont."

Truth Can Thwart Progress of Socialism

The Federal Security Agency argues that "about 30 per cent of our people cannot afford to pay for their own health services." In the same breath the same agency reports that the death rate for the United States in 1948 was the lowest in the history of the country. Also, since 1935 the percentage of total births delivered in hospitals has more than doubled, being 84.8 per cent as of 1947. Maternal mortality has decreased to a new low. General health conditions in the United States are excellent, and are still improving.

After presenting these truths, *The Journal of the Michigan State Medical Society* remarks, "This gives the bureaucrats a logical (?) reason for changing the program of health service."

Continued medical progress is one of the best ways to combat compulsory health insurance. The above journal says:

> "The government now is responsible for an unknown number of our people, variously estimated from 20 to 30 million, who receive complete health service, and the government is having difficulty getting more doctors on its various hospital staffs. If the National Health Service Program were adopted, the number of doctors available would be so inadequate that even Ewing estimates it would take twenty years to get the program operating. More doctors cannot be created by passing a law! They need many years of education and training.
>
> "James F. Byrnes, former Associate Justice of the Supreme Court, former Secretary of State, in a recent article in *Collier's Magazine* (March 4), says:
>
> 'If the Politicians will let the doctors alone, the government will be able to continue its boasts about improving health conditions.'"

SOCIALISM—A STEP TOWARD COMMUNISM

Socialism is often thought of as the form of government which will, if left to function and grow, most likely develop into communism. To speed the evolution from capitalism to communism, leftists are now advocating establishment of socialism as an essential step on the way to communism. Les Arends, writing in "Inside News of Congress," comments:

> "Those arguing for the Truman program have been heard to say that 'A little socialism is a good thing . . . socialism is the best insurance against communism.' An answer to this comes from no less a person than the new War Minister in Britain's socialistic government, John Strachey.
>
> "In 1936 Strachey wrote: 'It is impossible to establish communism as the immediate successor to capitalism. It is accordingly proposed to establish socialism which can be put in the place of our present decaying capitalism. Hence communists work for the establishment of socialism as a necessary transition stage on the road to communism.'"

BRITAIN'S SOCIALISM—A FRANKENSTEIN MONSTER???

As would be expected, the cost of Britain's socialism is far beyond original estimates. The millions of extra pounds being spent annually may prove to be like Frankenstein's monster and turn against those who helped create the system. Yet, the British people are not receiving extra benefits for that money, because it is now being spent only to keep this system which won out so narrowly in the last election, and which does not improve its services, but only eats more money.

Raymond Moley, writing in *Newsweek* recently, quotes convincing figures about the high cost of socialism:

> "In the first fiscal year during which people fully appreciated that they could get something for nothing, 1948-49, the original estimate of cost to the government was 200,000,000 pounds. The cost proved to be 278,000,000 pounds. Presumably Health Minister Bevan and his colleagues thought that a total of 261,000,000 pounds would be enough for 1949-50. The final figure it now seems will be 359,000,000 pounds. But the health service has also drawn 41,000,000 pounds from the national insurance fund and 16,000,000 pounds from ratepayers. So the health service will really cost 416,000,000 pounds, and it is believed that next year it will go to 450,000,000 pounds."

Mr. Moley quotes the London *Times'* dry comment on this situation, that before the final supplementary appropriations are made, Bevan will have to convince Parliament "that he is running and not being run by the service he has created."

The conflict within the concept of a welfare state is then explained by Mr. Moley:

> "At that point (when the 'monster' gets out of hand) the Socialist faces an uncomfortable dilemma.

He can completely tighten his control over all concerned—doctors, patients, and local authorities. Or he must surrender his socialism and accept the Conservative principle of a minimum standard based upon proven need.

"Something of the same problem is bound to face all socialistic services. Socialism by embracing a program of fair shares, which really means equal shares, must, if it assures liberty of choice, reach the point where the means no longer exist to permit every recipient to be the judge of his needs. Then government must impose iron controls if it is to keep its socialism. For there can never be equality of demand or equality of productive capacity. When equality is enforced, liberty disappears. That is the irreconcilable conflict within the concept of a welfare state."

OF MICE AND MEN

The lowly mouse is a definite parallel to those ho would nibble or gulp down the "free cheese" f socialism, according to the General Electric *ommentator,* quoted in the Harding College etter:

"Could the mouse, by any chance, get the answer by observing what's happened to others around him?

"Sure, but he won't. Being a mouse, he'll grab—or maybe just timidly nibble—and die!

"What about men? How do too many of us supposedly superior animals act?

"Just like the mouse, just like we had been studying up to be half-wits.

"And we do so in the face of vivid examples—right under our noses and all over the world—that show us we shouldn't.

"Some men have grabbed at something-for-nothing, or 'free cheese,' in sudden and violent communist revolutions.

"Others have only nibbled at 'free cheese' in timid and supposedly harmless collectivist bites—one after another—that will always spring the trap and result in lower living standards and loss of liberty, dignity, and spiritual well-being . . .

"Are we going to prove we're mice—or men?"

ADMINISTRATION CALLED A "PLAYING REFEREE"

With primaries over in some states and still to ause much discussion in others, the *Pennsyl-ania Medical Journal* urges voters to register and ote, using a sports analogy to emphasize its imortance:

"What a furore such a violent reversion of the rules of the game would occasion at a football contest. How the paying spectators would overrun the field to eliminate the referee who claimed a touchdown.

"Why don't the American taxpayers overrun the political field on election day and eliminate the administration that as a 'playing referee' carries the ball with tax money and runs the potato and the egg business, utilities, etc.?

"The answer is that (1) too many taxpayers don't understand the Constitutional limitations against governmental interference with 'free enterprise'; (2) too many of those who do understand don't speak out to their neighbors, don't register to vote, and don't support candidates for office who do support the Constitution of the United States."

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

230 Lowry Medical Arts Building
St. Paul, Minnesota

Julian F. DuBois, M.D., Secretary

Waterloo, Iowa, Physician Sentenced for Attempted Abortion on Minneapolis Woman

Re. State of Iowa vs. Gabriel Bickley Lichty.

On April 27, 1950, Dr. Gabriel B. Lichty, 401½ W. 4th St., Waterloo, Iowa, entered a plea of guilty in the District Court of Black Hawk County, Iowa, to a charge of attempted abortion, and was sentenced to five years in the State Prison at Fort Madison, Iowa. The sentence was imposed by Judge E. T. Evans. Dr. Lichty, who was born in 1903, graduated from the Medical School of the University of Minnesota, in 1927. He is not licensed in Minnesota, but was licensed in Iowa, in 1928.

On October 30, 1949, the Minneapolis Police Department notified the Minnesota State Board of Medical Examiners that a 21-year-old Minneapolis woman was seriously ill in Minneapolis General Hospital following a criminal abortion. Subsequent investigation disclosed that the abortion was performed by Dr. Lichty on October 28, 1949, at his office in Waterloo, and that he was paid $200 for his services. Statements were also obtained from a 26-year-old Minneapolis woman that Dr. Lichty had performed an abortion on her on July 7, 1949, and received $400 for his services. The signed statements were forwarded to the Iowa State Department of Health, and the prosecution of Dr. Lichty followed.

The Minnesota State Board of Medical Examiners wishes to acknowledge the excellent work done by the Minneapolis police officers who were assigned to the case by Mr. Thomas Jones, Superintendent of the Minneapolis Police Department, and also the splendid cooperation received from Mr. Michael J. Dillon, County Attorney of Hennepin County, in arranging for the appearance in Court at Waterloo, Iowa, of the various witnesses in Minneapolis who had knowledge of the facts in both abortion cases.

Minneapolis Man Pleads Guilty in Fake Abortion Racket

Re. State of Minnesota vs. Walter F. Catterson.

On June 1, 1950, Walter F. Catterson, fifty years of age, residing at 624 8th Avenue So., Minneapolis, was sentenced by the Hon. William C. Larson, Judge of the District Court of Hennepin County, to a term of two to eight years in the State Prison at Stillwater. Catterson had entered a plea of guilty on April 27, 1950, to

THE POSTTHROMBOTIC SYNDROME

NATHAN C. PLIMPTON, M.D.
Minneapolis, Minnesota

Deep venous thrombosis of the femoral and iliac veins produces permanent changes in the limb that affect the physiology of the venous circulation. This altered physiology results in the gradual development of a syndrome climaxed by pain, edema, varicose veins, induration of the subcutaneous tissues above the internal malleolus, pigmentation, a chronic dermatitis of the skin of the lower leg, and chronic ulceration. These symptoms usually develop in this order as early as one to two years or as long as fifteen to twenty years after thrombosis.

It remained for the acumen of John Homans[3] to differentiate between ulcers due to varicose veins and those secondary to thrombophlebitis. In a paper published in 1917, he pointed out that the effect of phlebitis following childbirth, fevers, and intra-abdominal operations is to destroy the valves of the veins in which the inflammation occurs. After recanalization, the lumen remains as a hard, straight, palpable cord through which back pressure is maintained from above as in the case of the typical varicose veins. He proposed radical excision of the ulcer with subsequent skin grafts as a type of treatment. This procedure met with fair success, although in the light of our present knowledge, it was not designed to correct the pathological physiology of the posthrombotic extremity.

Buxton,[1] in 1945, and Buxton and Coller,[2] in 1946, were the first to report interruption of the superficial femoral vein for the treatment of the postthrombotic extremity. They reported a series of twenty-one patients with twenty-three ligations. Of fourteen patients with ulceration, thirteen healed satisfactorily. In the group of seven patients without ulceration, the improvement was not as dramatic; the relief of pain was the most striking result.

Homans,[4] in 1945, was the first to report the division of both the superficial femoral and greater saphenous veins in the treatment of the postthrombotic extremity. He recommended this form of treatment in those cases presenting venous congestion yet with little or no edema. It was from this group of patients that surgery had been withheld in the past because all the distended veins were still considered capable of carrying blood uphill and must not be disturbed. In another group of patients in which there was pain, edema and ulceration, Homans was content to treat more conservatively with sympathetic blocks.

Last year, Linton and Hardy[5] of Boston published a rather impressive report based on forty-nine patients with thrombotic sequelae who were treated by division of the superficial femoral vein and stripping the greater and lesser saphenous veins and their larger tributaries. The incidence of bilateral involvement was 47 per cent. The symptoms of ulceration, stasis dermatitis and pain showed most spectacular improvement. Stasis cellulitis was the least satisfactorily handled. However, none of the patients was worsened by surgery.

An understanding of the pathological physiology underlying the postthrombotic syndrome is essential to satisfactory treatment. Linton makes two important points. First, it is believed that with the exception of pain and edema, the symptoms of this condition do not appear immediately, but only after the veins have become canalized. He observed that 58 per cent of the ulcers in his series occurred between one and ten years after the attack of phlebitis. Second, that postthrombotic ulcerations, unless extremely large, can be healed merely by best rest and elevation. This rather impractical method of correcting the increased venous pressure reduced also the lymphedema, thus establishing a more normal venous and lymphatic circulation.

It has been shown experimentally that after a vein canalizes following thrombophlebitis, the valves are incompetent. It has also been shown experimentally that when the saphenous valves are incompetent, a high pressure is maintained in that vein during muscular activity, whereas with a normal competent valvular system, exercise reduces the venous pressure. A comparable situation undoubtedly exists in the postthrombotic extremity in which the valves of the deep veins are incompetent. The pressure in the veins under these conditions is far above the colloid osmotic pressure of blood, resulting in an increase in lymph formation. As a result of the previous phlebitis, the lymphatics have been damaged so that they do not function normally in the postthrombotic state.

The induration seen over the inside of the lower leg is believed to be secondary to the increased venous pressure. The brown pigmentation of the skin of this area is due to the capillary hemorrhages also secondary to the increased venous pressure. The varicose veins are thought to be secondary to the incompetent communicating veins which transmit the raised pressures to the saphenous systems. With these thoughts in mind, it is easy to understand how necessary it is to interrupt both the saphenous as well as the superficial femoral veins in order to eliminate both channels that make the increased venous pressure a possibility. Linton has recommended that the results with the stripping of the saphenous veins are better than when they are merely ligated and injected with a sclerosing solution. It is his thought that with these veins gone, the old channels are much less likely to be opened up. He further states that in his hands lumbar sympathetic blocks are an unsatisfactory approach to this problem, although Alton Oschner does claim success.

The diagnosis of patients suitable for the ligation treatment of this condition is determined by physical examination as well as the history of an attack of thrombophlebitis. The most important part of the examination is to ascertain the competency of the valves of the deep-communicating and superficial venous systems. This is done by the Trendelenburg test. The veins are emptied by elevating the extremity, a rubber tourniquet is applied to the leg just distal to the knee and sufficiently tight to occlude the superficial veins. The patient then stands up. If the superficial veins fill quickly from below the tourniquet, an incompetency is demonstrated in the valves of the deep and communicating veins.

Report of Case

A man, aged forty-eight, gave the story of developing bilateral thrombophlebitis in 1945 during an attack of pericarditis. The first symptom that followed this complication was a persistent swelling that accompanied the original condition. Associated with this were pain and fatigue in his legs on exercise. Walking as little as two blocks never failed to produce considerable discomfort in his calves. Approximately one year after his phlebitis, he noted a gradual enlarging of the superficial veins of both legs. During this postphlebitic period, the symptoms in his left leg have been noticeably worse than the right. With the aid of elastic bandages and stockings he was able to control the swelling, but the subjective symptoms were not markedly altered. During the summer of 1948, approximately three years after his thrombophlebitis, he developed pigmented areas below each malleolus. These were considered to be potential ulcers. Associated with this was an induration of the surrounding subcutaneous tissue with burning and itching of the colored skin.

My first treatment consisted of injecting some of the more dilated varicosities and the application of elastic bandages. The article by Linton and Hardy suggested what seemed to me a rational approach to this problem, for her was a typical case of the postthrombotic syndrome. Accordingly, on December 30 of last year, the patient was subjected to the following operation. Under general anesthesia, the left superficial femoral vein distal to the profunda femoris and upper greater saphenous veins was exposed. The intraluminal pressure of the former after it had been occluded proximally was observed to be 15 centimeters of water. After the saphenous was occluded, it rose to 24 centimeters. If the latter is over 30, it is advised to divide the saphenous at a later date. Accordingly, these veins were divided and ligated. The diameter of the superficial femoral was observed to be approximately 7 millimeters. Following this, all of the larger varicosities were stripped by means of an intraluminal vein stripper. Multiple short incisions were necessary to accomplish this.

The same operation was done on the right side. There was more scarring and fibrosis of the superficial femoral vein than on the left. The lumen was only 2 millimeters in diameter which accounted for my inability to find the lumen with the exploring needle. Consequently, no pressures were taken. It was conjectured at the time that the reason for the fewer symptoms on the right than on the left might be due to smaller caliber of the superficial femoral vein. The superficial varicosities were then stripped on the right side. Pressure dressings were applied from the groins to the metatarsals. The postoperative course was uneventful except for a lymphorrhea that occurred in the right inguinal incision and lasted for nearly four weeks.

The patient states that since the operation his legs feel better than they have at any time since his original attack of thrombophlebitis. The subjective symptoms of fatigue in his calves and burning and itching below the malleoli are gone. The pigmented areas persist, but the induration in the subcutaneous tissues is no longer present. A few rather moderate sized varicosities that were missed in the stripping have enlarged, but they are being satisfactorily handled by injections. There was some residual lymphedema which required elastic bandage support. This has gradually improved until at present his left leg requires no support, but his right will swell slightly without it.

Summary

1. A brief review of the literature on the postthrombotic syndrome is presented.

2. The pathological physiology of this condition is discussed along with the rationale for a proposed method of treatment.

3. A case of the postthrombotic syndrome is presented along with the results of surgical treatment.

VENOGRAPHY IN THE POSTPHLEBITIC SYNDROME

CLARENCE V. KUSZ, M.D.
Minneapolis, Minnesota

Iliofemoral thrombophlebitis is usually followed in months to years by a syndrome characterized by edema, pain, recurrent cellulitis, pigmentation and ulceration. Collectively, this is known as the postphlebitic syndrome.

The pathological physiology of the postphlebitic syndrome and a means by which this may be corrected were set forth by Homans in 1941.[4] He stated that the femoral system once thrombosed must suffer the loss of all its valves so that when the body is erect the venous return must take collateral valved pathways. Blood must pour down a valveless vein, and it is, there-

fore, reasonable to assume that an old sclerosed and canalized femoral vein or external iliac vein is better divided.

Bauer[1] was probably the first to demonstrate the pathological physiology of the deep venous system that followed an iliofemoral thrombophlebitis. In 1948, he reported his findings using direct venography. Bauer cannulated the superficial femoral vein directly, after surgical exposure. Radio-opaque material was then introduced into the superficial femoral vein while the patient was in a 45-degree upright position on an x-ray apparatus. X-ray exposures were then made. Bauer was able to show that following an iliofemoral thrombophlebitis in patients with the postphlebitic syndrome, recanalization had taken place in the superficial femoral vein and that the radio-opaque substance would flow downward even into the popliteal vein and occasionally into the veins of the calf. In the normal superficial femoral vein, the material would be held by competent valves and would pass upward. No dye was seen to reflux into the deep veins of the thigh.

We have been able to simplify the technique of direct femoral venography and have been able to demonstrate incompetency in the deep femoral vein as well as in the superficial femoral vein. By means of a popliteal venogram, we have been able to show that many times there exists in the postphlebitic leg a gross communication between the superficial femoral vein and the profunda femoris vein above the knee. Because of these findings, we have thought it to be more logical that ligation of the popliteal instead of the superficial femoral vein be carried out in the postphlebitic syndrome.

The technique used for direct femoral venography is essentially the same as Bauer's, except that a percutaneous entrance into the femoral vein is carried out. Femoral venography is carried out as a diagnostic aid before any operative procedure is decided upon.

The patient is placed on a tilted x-ray table in a 45-degree upright position. After infiltration with novo-

caine, a direct puncture is made into a common femoral vein just below the inguinal ligament. A 19-gauge needle s used. Thirty cubic centimeters of 35 per cent diodrast are then injected rapidly. An x-ray exposure is made mmediately following the injection, and a second exposure is made one minute later.

The popliteal venogram is carried out in the 54-degree upright position with the patient face downward on the x-ray table. A direct entrance is made into the popliteal vein at the level of the upper border of the patella, and 30 cubic centimeters of 35 per cent diodrast are njected. X-ray exposures are made immediately and one minute following the injection.

Each patient is tested for sensitivity to diodrast before njection. The occular test has been used. In over 100 njections, about 25 per cent of the patients had nausea but only six patients actually vomited following the njection. The nausea is usually completely gone in about three minutes.

We have reached the following conclusions after more than 100 femoral and popliteal venographic studies:

1. In the normally functioning femoral vein, valves are usually present and they will prevent the radio-opaque material from flowing downward (Fig. 1, *A* and *B*).
2. In the normal femoral venogram, the iliac vein is well filled and the one-minute exposure will show a complete absence of radio-opaque material except in the valve sinuses where it will remain for as long as five minutes.
3. In the absence of valves or in a recanalized femoral vein, femoral venography will show that the opaque substance has refluxed into the veins of the thigh, at times even into the veins of the calf (Figs. 2 *A*, 3 *A* and 4 *A*).
4. In patients with the postphlebitic syndrome who show absence or incompetence of the valves, the one-minute exposure will show the presence of the radio-opaque material in the veins of the thigh. The amount remaining depends upon the degree of slowing of the return circulation and the presence of adequate functioning collaterals (Fig. 4*B*).
5. In patients who present the picture of a postphlebitic syndrome without a history of iliofemoral thrombophlebitis, the femoral venogram will show reflux. In these patients, the veins will be seen as a large dilated straight tube without valves. Occasionally, valves are present but are incompetent (Fig. 3 *A*).
6. The profunda femoris vein can be incompetent either alone (Fig. 5) or together with the superficial femoral vein (Fig. 4).
7. By the use of the popliteal venogram, we have been able to show that often there exists a gross communi-

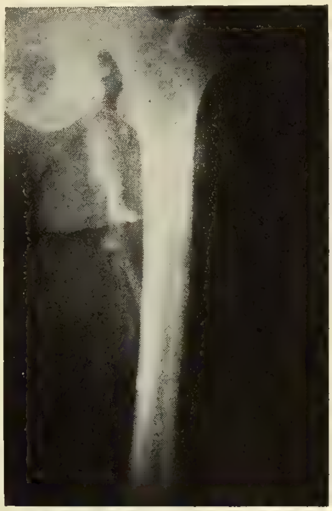

Fig. 5—Femoral venogram, showing reflux into profunda femoris vein alone.

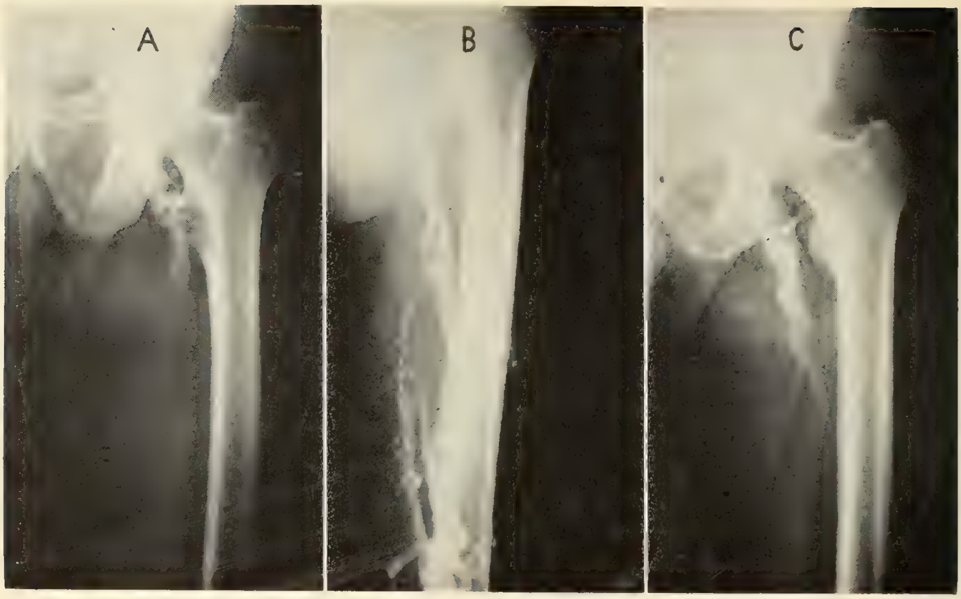

Fig. 6. *A*—Femoral venogram, showing evidence of recanalization in iliac vein and femoral vein. At this time, it was thought that the superficial femoral vein was involved, and a superficial femoral vein ligation was carried out without relief of pain or healing of ulcer in spite of two skin graftings.

B—Popliteal venogram on patient four months after superficial femoral vein ligation. The gross communication between the superficial femoral and profunda femoris is clearly shown.

C—Femoral venogram on patient in *A* and *B*, four months after superficial femoral vein ligation. This shows that the profunda femoris vein is incompetent. A popliteal vein ligation was carried out. A skin graft was then applied to the ulcer which healed well, and the patient had complete relief of pain following the popliteal ligation.

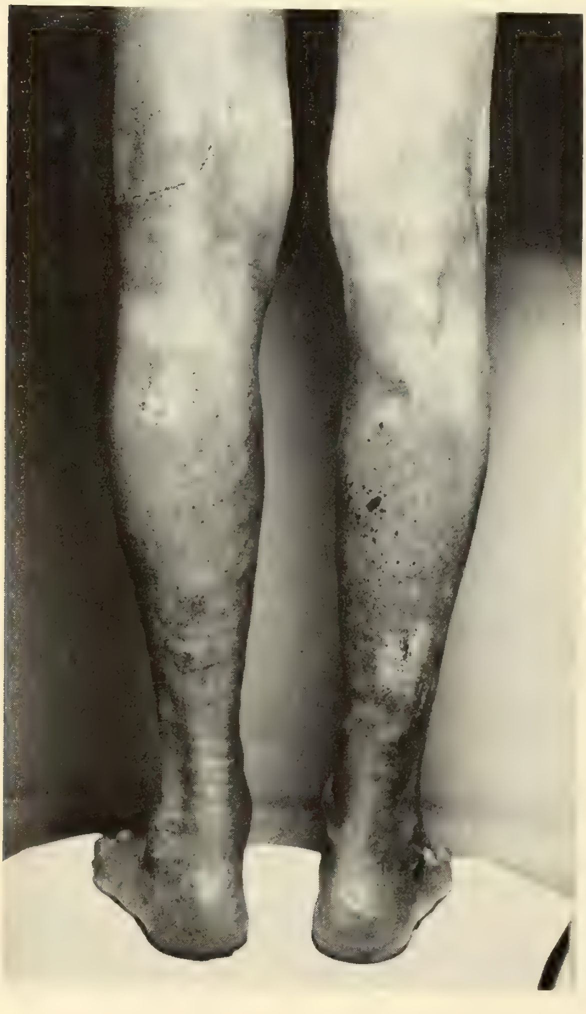

Fig. 7. The incision used to ligate the popliteal vein.

cation between the profunda femoris vein and the superficial femoral vein just above the popliteal space. Ligation of the superficial femoral vein in these patients will not benefit the leg because the pressure is then transferred to the profunda vein which in turn transfers the increased pressure again into the popliteal vein and into the lower leg. This is especially true in patients in whom the profunda vein is incompetent at the time. In this type of patient, ligation of the superficial femoral vein and the profunda femoris vein could be carried out with benefit to the lower leg, but we have found increased edema in the thigh in two patients in whom this was done. The popliteal vein is the logical site of ligation. This will stop the reverse pressure from both the superficial femoral and the profunda femoris vein and will not interfere with collateral channels in the thigh (Figs. *2B*, 3 *B* and 6 *B*).

8. In the popliteal venogram, as in the femoral venogram, the one-minute film will show the veins of the thigh to be cleared of dye in the normal vein, but still present in the incompetent vein.

Superficial femoral vein ligation for the postphlebitic syndrome was first reported by Buxton[2] in 1944. He found that in many cases ulcers could be healed, but that pain and edema were not uniformly relieved. Linton[5] reported 80 per cent healing of ulcers and 63 per cent relief of pain following ligation of the superficial femoral vein. Glasser[3] reported one recurrence of ulcer in six patients who were followed for five years following a superficial femoral vein ligation for the postphlebitic syndrome. However, he reports a 50 per cent recurrence in those followed for only two years. Bauer[1] reports relief of pain and healing of ulcers in all patients following ligation of the popliteal vein. Our results following popliteal vein ligation compare closely with those found by Bauer. However, our longest follow-up has been only eight months. Relief of pain following the ligation is dramatic in those patients who give a history of a pressure pain and in whom reflux is shown by venographic studies.

Together with the popliteal vein ligation, we have ligated and stripped, with the intraluminal vein stripper, all patients who had an incompetent saphenous system. Superficial varicosities that remained were then treated by injections.

Summary

The technique of direct femoral venography and popliteal venography and the findings as they refer to the postphlebitic syndrome are presented. Incompetency of the valves of the femoral venous system accounts for a large part of the postphlebitic syndrome. Not only can the superficial femoral vein be incompetent alone, but the pathologic physiology may extend into the profunda femoris vein as well. The femoral venogram is used to study this pathological physiology. By means of the popliteal venogram, the anatomy of the venous system of the thigh can be studied, and it has been found that in a large number of cases there exists a gross communication between the superficial femoral vein and the profunda femoris vein just above the popliteal space. Because of the venographic findings, we have felt that a popliteal vein ligation should be performed in preference to the superficial femoral vein ligation in the postphlebitic syndrome. Results have been encouraging, especially in relief of pain and healing of ulcers.

THE RETURN OF "VEIN STRIPPING"

FRANK W. QUATTLEBAUM, M.D.

Saint Paul, Minnesota

Ligation and retrograde injection are currently the most widely used method of treating varicose veins. Quite recently the so-called "stripping procedure," a method used many years ago, is gaining popularity. The current method of treatment was preceded by many frustrating efforts in other avenues.

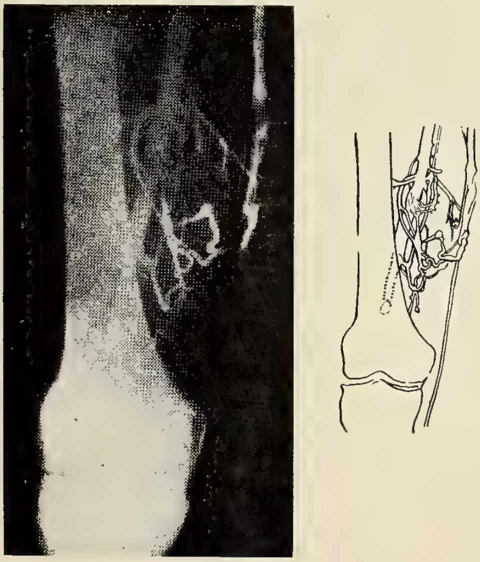

Fig. 1.

Throughout the ages, many procedures such as ligation, incision, excision, cautery, bleeding, compression sutures, etc., were suggested, tried and abandoned.

Around 1850 attempts were made to obliterate varicose veins by injection alone. Unsatisfactory fluids for injection purposes plus the lack of understanding of the fundamental physio-pathologic condition at fault, doomed this form of therapy to failure.

From 1880 to the early twenties, it was the vogue to do extremely radical procedures. It would seem that the symptoms sometimes did not warrant such extreme measures. Schede made multiple circular incisions down to the fascia from the groin to the calf, ligating all veins encountered. In 1884, Modelung[8] extirpated the entire saphenous vein through a long vertical incision from the groin to the ankle. In 1908, Friedel[4] described a long spiral incision from the groin downward, encircling the leg several times, packed wide open and allowed to granulate. Needless to say, the "vein stripping" procedure as introduced by Mayo[9] in 1906 and by Babcock[2] in 1907, were accompanied by too many complications. With the other radical procedures, it was abandoned as soon as a safer procedure was available.

The procedure became available in 1916 when John Homan[6] described the reverse flow phenomena in the saphenous vein, designated the saphenofemoral junction as the proper site of ligation and stressed ligation of all collateral branches. The operation is today performed as he described it in 1916. Further refinement was added in 1930 when Higgins and Kettel developed "sodium morrhuate" for retrograde injection. This was the first solution available with a high sclerotic index and yet relatively safe for the patient.

Gradually, then, a simple procedure evolved, easily performed with a high degree of effectiveness and a relatively low incidence of complications. It was to be expected that the ligation-retrograde injection technique quickly caught the fancy of all surgeons and has been done the past three decades almost to the exclusion of all other methods.

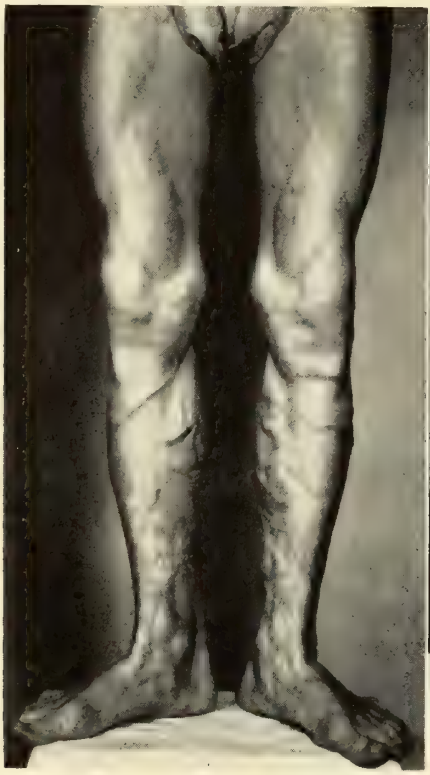

Fig. 2.

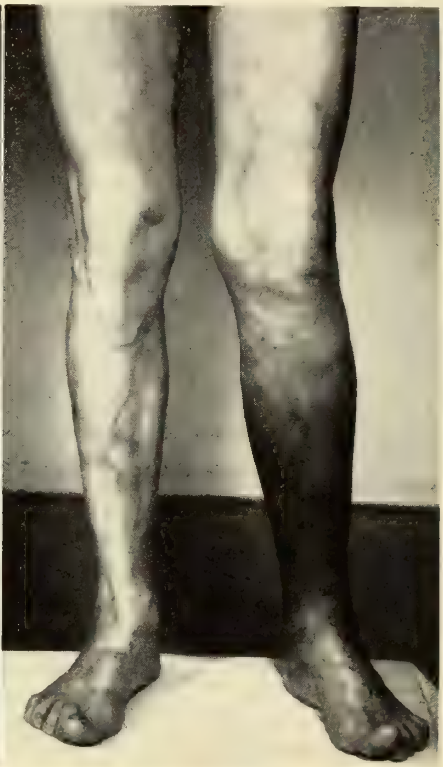

Fig. 3.

Thus we have gone through many phases and find ourselves repeating the cycle again by reviving one of the older, more radical procedures, namely, the "stripping" procedure. Why is this procedure being revived? Is it now a safer operation than it was in 1910? Is it a more effective operation, associated with fewer recurrences than the conventional ligation injection technique?

The "stripping" procedure is unquestionably safer than it was between 1910 and 1920. During that period the patients were left in bed for one to two weeks. They are now ambulated the evening of operation. The extensive openings into tissue planes are not as hazardous with better surgical and operating room care and with the antibiotics as adjuncts. Whereas the thromboembolic complications were quite common in the earlier days of "stripping," they are almost unknown today, and the availability of anticoagulants leaves one much more secure as to this complication. In approximately 200 cases of "stripping" at the Minneapolis Veterans Hospital, only one questionable case of calf phlebitis was observed and no embolic phenomena.

It is apparent that one should have a two-year follow-up to determine recurrences in varicose veins. It is our impression, however, that the recurrence rate is definitely less with the "stripping" than with the conventional methods. Hodge et al,[5] Stalker,[13] Linton[7] and McElwee and Maisel[10] now prefer to treat varicose veins by "stripping."

Some space should be devoted to the dangers of retrograde injections with the conventional method of handling varicose veins. This hazard, of course, is not present when the veins are "stripped." Hodge,[5] Slevin,[12] Atlas,[1] Witter,[14] and Boyd and Robertson[3] do not use retrograde injections because of the dangers of introducing a deep phlebitis. When the vein only is ligated, one has done a rather incomplete operation. Boyd, et al[3] and McPheeters[11] have both demonstrated the presence of the radiopaque material in the femoral vein quite soon after it was injected into the superficial saphenous vein. One is then depending upon the size and rate of flow in the deep vein to prevent or minimize the phlebitis. I have been particularly impressed in obtaining a history in the long-standing post-phlebitic syndromes that many of these people unequivocally volunteered that the symptoms of their deep vein involvement gradually began after superficial vein ligation and retrograde injection. Figure 1 demonstrates the amount of dye that sometimes passes immediately into the deep circulation after being injected into the distal end of the divided saphenous vein. When the injected material is an irritating solution, it is obvious that deep vein damage can result.

Indications for stripping are variable. I believe the following would be acceptable in any quarter:

1. Extremely large veins (Fig. 2).
2. Inactive deep phlebitis with incompetent superficial veins (Fig. 3).
3. Multiple previous injections.
4. Recurrence following previous adequate ligations and retrograde injection.

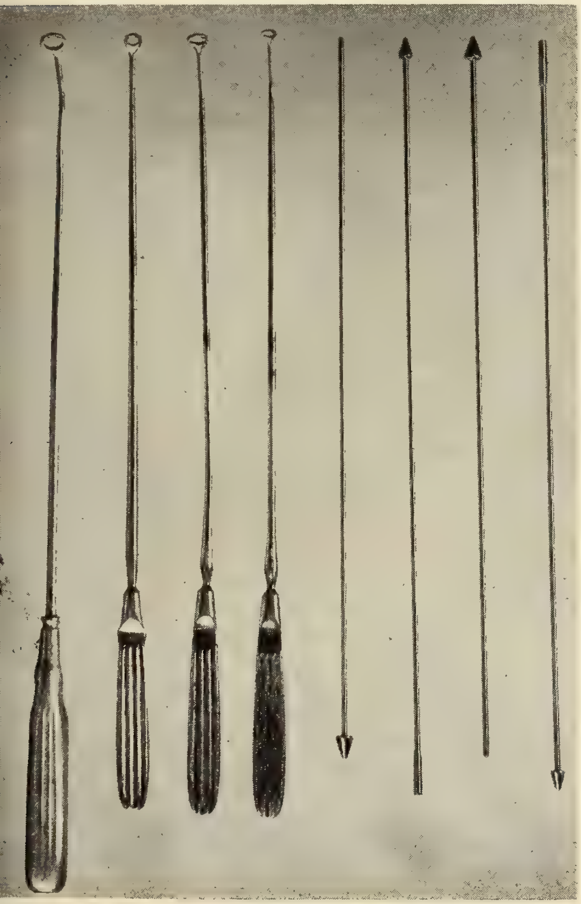

Fig. 4.

In my own private work, however, I go beyond the above indications and use the "stripping" procedure almost to the exclusion of all other methods. To date, I have been satisfied with the immediate and late results.

Technique

A question of technique in this procedure always begins with the type of "stripper" used. We have been satisfied with the Babcock intraluminal stripper with the occasional use of a small Mayo extraluminal stripper for small tributaries (Fig. 4). Several other types of instruments with various innovations are available. Of these the Myers stripper, devised by Dr. Tom Myers of Rochester, Minnesota, is an excellent intraluminal stripper. It permits one to strip the vein upward from the ankle to the divided segment in the groin. An adequate ligation of the saphenous vein at the juncture with the femoral vein, including all collateral branches, is mandatory. The saphenofemoral juncture should be clearly dissected and the femoral vein clearly identified completely around the juncture. Stripping of the distal segment proceeds according to the individual technique. The patient should always be placed on the operating table in slight Trendelenburg position. This so lowers the pressure in the femoral vein that the torn ends of the communicators bleed into the femoral vein lumen rather than into the subcutaneous tissues. One is amazed often at the minimal bleeding encountered from this procedure which appears on the surface so traumatic. In stripping the distal segment of the saphenous vein from the groin, one can often go to the ankle and withdraw the vein in one long segment. Sometimes, a communicator at the knee traps the tip of the stripper, and one has to divide the vein here and proceed again. With open ulcers at the ankle, one should strip down to the ulcer if possible. The ulcer does not have to be healed, but should be free from infection and covered by clean granulations.

With the patient still in Trendelenburg position at the completion of the procedure, two longitudinal folded towels are incorporated as pressure dressings over the bed of the excised saphenous vein by using two 4-inch Ace bandages from ankle to groin over the towels. The patient walks the evening of the operation. He is given a daily dose of procaine penicillin and can be dismissed in one or two days. With proper care regarding subcutaneous bleeding these patients have remarkably little post-operative disability. They are much more comfortable than following a retrograde injection of one of the sclerosing solutions.

Postoperatively, these patients must be followed until all residual veins are obliterated by office injections. These are not started for one month because often an enlarged residual vein is actually filled with soft clot and in a few weeks will begin to contract down. These patients on an average will require fewer postoperative injections than following other procedures. Often they require not a single injection, but are all instructed to return for routine six-month check-up and at periodic intervals thereafter.

FUNDAMENTAL PRINCIPLES IN THE TREATMENT OF VARICOSE VEINS

H. A. ALEXANDER, M.D.
Minneapolis, Minnesota

One often hears this complaint: "There is so much confusion and contradictory advice about vascular conditions that it is impossible for the average doctor to know what is best for his patient." It is my purpose to emphasize that there is general agreement on basic, fundamental principles, and these fundamental principles are very simple and easily understood. The differences of opinion are chiefly as regards which of two or more procedures will produce the best results.

There is general agreement that heredity and phlebitis are probably the two most important etiological factors in the development of varicose veins. Any varicose vein, whether degenerative or postphlebitic, can be eradicated, but the tendency to form new veins will still be present. This tendency to form new veins can be modified by proper care, but cannot be eliminated. Any doctor who accepts a patient with this tendency and eliminates the existing veins has only fired the opening gun in a war that will last as long as the patient lives. The patient must thoroughly understand, before any treatment is started, that there are several different types of treatment but that none of them is perfect; that regardless of which type of treatment is used, he will need regular care, in the average case once a year, as long as he lives. Help him to understand by explaining that it is exactly the same type of continued deterioration that requires his going to the dentist at regular intervals.

There is general agreement on the fundamental principles of treatment of superficial varicose veins. Small veins can be destroyed by injection of a sclerosing solution. Larger veins, especially those veins which are subjected to considerable intravenous pressure, are best treated operatively and here again there is important agreement. The two essentials are, first, a high ligation, and second, destruction or removal of the varicosed segments. I am speaking about superficial veins. I believe that judgment on the femoral and popliteal vein ligations should be held in reserve until we see how long the good results last. In those deep vein ligations, a fundamental principle is violated; the distal segment is not eradicated.

There are three generally accepted groups or types of varicose vein surgery: (1) high ligation plus stripping; (2) high ligation plus multiple incisions for ligation of perforators; and (3) high ligation plus retrograde injection.

All three groups have a high ligation as an essential part. Any one of the three types of treatment fails if the long saphenous vein is not ligated proximal to the tributaries that join it very close to the femoral vein. I am sure that this is the most common cause of failure. The only way one can be sure he is ligating proximal to these tributaries is to continue the dissection until he can ligate the saphenous flush at the junction with the femoral.

The second essential of varicose vein surgery, after high ligation has been completed, is the destruction or removal of the remaining varicose segments. This can be accomplished by three or more methods. No one method is ideal or perfect. Stripping works well if the veins are straight and tubelike. Retrograde injection is better if the veins are extremely tortuous. Separate incisions for ligation of incompetent perforators may be indicated even in the extremity having one of the above-mentioned types of treatment. Injections of sclerosing agent, to eliminate remaining varices, can be used as a follow-up treatment, regardless of the type of original surgery.

There are advantages and disadvantages in all three methods. I do not believe we should be committed exclusively to one method but should determine, in each case, which method will best eliminate the varices in that particular case. An internist does not prescribe the same kind of diet for all his patients; neither should a vein surgeon commit himself to one procedure, regardless of what type of veins his patient has.

The stripping procedure is described elsewhere on the program.

Multiple incisions for ligation of incompetent perforators are advocated and described by Sherman in the August 1949 issue of *Annals of Surgery*. Sherman uses a high ligation plus retrograde injection of a small amount of sclerosing agent, but he feels that this "often fails to produce maximum benefits." In an attempt to improve his results, he studied the anatomy of the lower extremity intensively. He dissected 229 lower extremities on cadavers, and made about 1500 radical surgical dissections. From these extensive studies, he came to the conclusion that there are perforator veins, at fairly uniform locations, that can become incompetent. He advises multiple incisions for ligation of these incompetent perforators, emphasizing that, to be successful, such ligations must be made deep under the fascia, deep in the muscle, if possible at the junction with a major vessel of the deep venous system. He describes the stripping procedure as "futile," because it leaves the collateral and accessory perforator veins undisturbed. "The reflux of blood through the incompetent leg perforators is not altered, and the procedure fails to accomplish its purpose." He finds from one to fourteen incompetent perforators in a single leg. Seven mild embolisms occurred in his series. His operative time for one extremity is three hours.

Obviously, his system is not ideal for several reasons.

1. A general anesthetic is required and active motion cannot start until the anesthetic wears off.

2. Numerous scars constitute a cosmetic objection.

3. At least in our experience, what appears to be a perforator often turns out to be just a dilated vein.

4. Any surgical procedure that takes an experienced specialist three hours for one leg will require a longer time for a surgeon who does that procedure only occasionally. In other words, a patient with bilateral varicose veins will require perhaps 6 or 8 hours for the average surgeon, exclusive of preoperative study and postoperative care.

The third, and I believe one of the best methods, is high ligation with retrograde injection. With teamwork, the patient with bilateral varicose veins can be operated upon in one hour. Only local anesthesia is necessary, and the patient is ambulatory immediately. Fast walking at frequent intervals is essential; it increases the safety and decreases the discomfort. The majority of these patients do not require a hospital bed and this, combined with the shorter time required for operation, makes the procedure less expensive. Dr. McPheeters can look back on several thousand consecutive ligations without a fatality or even a proven embolus. Gunnar Bauer, during his recent visit here, stated that he favors this method. It should be noted that if the surgeon suspects the presence of one or two incompetent perforators, he can easily care for them by novocaine infiltrations and a secondary incision immediately following the regular procedure. The retrograde injection can be made more effective by means of the "empty vein technique" in which the extremity is first elevated to drain the blood from the leg into the abdomen. Then, as the leg is lowered and the table is tilted so the patient's body is partially upright, the retrograde injection is made and gravity helps the solution go toward the foot. We are often able to get obliteration of varicose veins in the lower calf and ankle by this empty vein technique, and we believe it eliminates the need for the ureteral catheter sometimes employed to get the solution into the lower leg.

This retrograde injection method also is not perfect for several reasons.

1. The chemical phlebitis causes pain and soreness for several days.
2. A thin-walled vein, close to the skin, may produce a pigmentation. This can be minimized by draining pocketed areas of half clotted blood and by supportive bandaging to compress such veins.
3. Any sclerosing agent can cause an allergic reaction in a sensitized patient, varying from a mild urticaria to severe shock. It is wise to have ready an emergency box, with adrenalin, aminophyllin, anti-histaminics, et cetera.
4. The sclerosing solution, conceivably, could precipitate an acute phlebitis, especially if the patient has a thrombotic tendency. It should be used with care in any patient with a history of phlebitis, and not used at all, if the phlebitis is still active. But there is no justification for any doctor's telling a phlebitis patient "never let any doctor touch that leg." We repeatedly see large, foul-smelling, painful ulcers that have been present on swollen, pigmented legs, for months and sometimes years, because of a very positive order from the attending doctor: "Don't ever let any doctor touch that leg; if you do, you will probably lose the leg and perhaps lose your life."

Just as bad is another almost unbelievable order, "Never put an elastic bandage on that leg." These two instructions are probably based on the supposition that the deep venous system has been closed by the phlebitis, and that it stayed closed. That is not correct. Intravascular clotting in an artery seldom recanalizes, but in a vein it often does so. The obstruction of the deep phlebitis is temporarily compensated for by dilated, superficial veins, but within a few months a new canal in the deep vein can make the dilated superficial veins a liability instead of an asset. These dilated or varicosed veins then need at least conservative management. In that term is included three things: (1) activity; (2) occasional elevation during the day, and (3) supportive bandaging. It is advisable that patients with varicose vein tendency should lead an active rather than a sedentary life. A quick contraction of the calf muscles, such as occurs in walking briskly, will force the blood upward; thus the calf muscles act like a second heart, helping the return flow of blood to the trunk. Prolonged standing or sitting in one position such as occurs among dentists, barbers, elevator operators and streetcar motormen is not good. Edema gradually develops late in the day. The condition is usually progressive, and as time goes by the patient finds he develops the swelling earlier and earlier during the day. Also, it disappears less completely at night. This edema is a danger signal. If there is one fundamental principle that is generally agreed upon, it is this: edema is detrimental and must be prevented if possible. It is advisable for patients with a varicose vein tendency to lie down and elevate their legs at least twice a day. The length of the elevated period varies from five minutes to an hour, depending on the severity of the condition. While the legs are elevated above the level of the heart, gravity will help the return flow of blood, and the swelling should disappear. We advise our patients to examine their ankles each night at bedtime. If there is any swelling, it is a warning signal. If swelling has developed in spite of activity, and in spite of regular leg elevation, an elastic supportive bandage should be worn at least part time. "Wrap around" bandages give better support than the stocking type. They should be 4 inches wide for the average leg; a 2-inch width is almost useless. They must be applied snug enough to give firm pressure. Stasis is even more important if the patient becomes ill or is confined to bed for any reason. Blood flowing slowly through a vessel is much more likely to clot than blood flowing rapidly. Frequent motion, especially of the lower extremities, will increase the rate of blood flow and decrease the possibility of phlebitis and embolism. Many hospitals have established vascular committees to recommend routine measures and emergency procedures for vascular complications. Such a committee can make a detailed study of each complication that occurs, and be ready to make suggestions when the case is discussed at the monthly staff conference.

There is one very important consideration that should be emphasized. A patient with varicose veins has a progressive condition. Those patients in the late forty-year-old and early fifty-year-old groups, especially, tend to become worse and to develop complications. Some of them, on first examination, seem to need only conservative management, but, in view of the progressive nature of their disease, actually require radical treatment. The admittedly imperfect treatment for varicose veins must aim not only to relieve the symptoms now present but also to prevent more serious trouble in the future. In weighing the merits and the possibilities of each type of treatment, we must consider not only the immediate improvement but the duration of that improvement. How good will that leg be twenty-five years from now?

In conclusion, I would like to emphasize these points:

1. We can destroy any vein we can reach, but there is still no method by which we can prevent new veins from forming. This tendency to form new varicose veins makes regular follow-up care imperative, regardless of the type of treatment.

2. The essential feature of the surgical treatment of varicose veins is a good, high ligation. The dilated segment distal to the ligation can be destroyed or eliminated by several methods, each of which has advantages and disadvantages that should be considered in the light of the requirements of each individual case.

3. Stasis and edema are dangerous and detrimental. The co-operation of the patient in wearing supportive bandages and frequently contracting the calf muscles will minimize the dangers.

4. The "empty vein technique" for either retrograde injection or follow-up office injection allows greater concentration of the sclerosing agent and gives better results.

5. Untreated varicose veins become progressively worse. Treatment should not only relieve present symptoms but should also prevent future trouble. It is preventive medicine.

RESUME OF PRESENT-DAY CARE AND TREATMENT OF VARICOSE VEINS AND THEIR COMPLICATIONS

H. O. McPHEETERS, M.D.
Minneapolis, Minnesota

It certainly must be apparent by this time that the proper method of treating varicose veins is anything but a settled one. It would seem that such a common clinical disturbance would lend itself to the rapid development of a perfect, simple and complete cure. Such is not the case. A review of the medical literature of the past year shows that an article on some phase of the problem appeared in almost every journal published. After having cared for 25,000 varicose vein patients and having done ligations with retrograde injections on 6,400 of these patients, I have not yet settled on the right method. Because of this unsettled state of affairs and knowing that all new ideas on this subject are supposed to originate in the East, I arranged for a personal visit to Boston and spent four days with Dr. R. R. Linton, one day with Dr. Gerald Pratt in New York and one day in Chicago. After all the discussion generated by such a trip in addition to my own experience, I have now formed some very definite conclusions.

As Dr. Alexander has so clearly said, there are basic fundamentals in this treatment on which we all do agree.

We must accept the fact that this is a degenerative process developing as the years pass by and that our patients will have more varicose veins regardless of what method of treatment is used or how thoroughly it is carried out.

At the risk of repetition, I want to emphasize the fact that today all authorities agree that a definite reverse flow of blood has developed in any well-advanced and extensive case of varicose veins, and that any successful treatment must seek to check this at its source, wherever that may be.

As the other speakers have pointed out, this reverse flow of blood usually begins at the sapheno-femoral junction. This means *at* the junction and not 3 inches or 2 inches or even one-half inch below. The most common cause of failure in this work is the lack of appreciation of this fact. It is true that in many cases a simple ligation of the great saphenous vein may hold the process in check for a while, even without injections. Yet, it is also true that there is a large variation in the arrangement of the tributaries or branches of the saphenous vein near the foramen and that the reverse flow may develop through any of these as well as, or in addition to, the main saphenous vein itself. If this is true, then the ligation must be *above* all these tributaries and flush with the wall of the femoral vein, if we hope for a good result. As Dr. Sherman has pointed out in his classical dissections, there are many communicating branches throughout the entire leg, and a recurrence may develop through these, even though a high ligation has been well done. It is with the idea of closing these communicating veins that I have done my retrograde injections, while other men chose to remove the saphenous vein in one way or another. Sherman does the high ligation and injects sodium morrhuate distally and then proceeds to do his dissection. At times he injects the veins in the lower leg several days preoperatively. He says that this all lessens the hemorrhage at the time of dissection. He may spend three hours on the dissection of one leg and often four hours on a bilateral. His dissection is carried out with spreading dissection and incisions down the leg. Few men use the Mayo stripper any more. The Babcock stripper is also being replaced by the more flexible type, the Linton and Meyers.

I believe the best stripping is done by Linton and his students. He uses a soft, flexible intraluminal wire and strips or pulls out all the varicosed segments he can find. He does both the long and short saphenous veins at the same time. If the short saphenous is varicosed, he carries the stripping right down to the ankle. Many times the vein will be found to go directly under the old ulcer, or at the foot internally or externally directly into an open ulcer.

The stripping is carried out under pentothal or spinal anesthesia by preference. The table is tilted to 10 to 15 degrees. The Trendelenburg position is utilized during the operation, and there is but little hemorrhage. Postoperative pads are bandaged along the course of the stripped veins and an ace or adhesive bandage wrapped about the entire stripped area. The foot of the bed is raised on shock blocks, with each leg on a pillow. The legs are kept so for two days. The patient is told to get up and start walking twelve hours postoperative and at two-hour intervals after that. When not walking, the legs are supposed to be elevated. The bandages are removed on the fourth day and continued after that on the lower leg, only as long as the legs swell. The absence of postspinal headaches is attributed to the small needle used, 22 gauge, and the technique as well as the small amount used (12 mg. of Pontocaine, as a rule).

After having done 6,400 varicose vein ligations with retrograde injections of the sclerosing solution, I admit that the retrograde injection following the high ligation falls short of perfection in that the communicating veins in the large and extensive cases cannot be adequately, completely and permanently closed. They often recanalize and become the source of a recurrence or a new varicose vein development. If the vein in the superficial fat is torn off and removed, this cannot happen. When sufficient sclerosing solution is injected to sclerose the vein well, the chemical phlebitis that develops is so severe and painful in the extensive case with large varices, that the patient is almost incapacitated. The veins are so sore, the patient can hardly walk, and yet he must walk to avoid emboli. As the large thrombosed segments liquefy, they must be drained or the soreness will persist, the pigmentation will be severe, and they will be the source of new varicose veins. For these reasons, I believe the thorough stripping is the best procedure in all the extensive cases, and because of the extensive collaterals I plan to use it for all bad cases of the short saphenous group. I have seen many cases of varicose veins in patients who have been stripped, but there should be fewer varices develop subsequently in any patient well ligated and stripped than by any other method.

I hardly feel able to comment on the work of Dr. Kusz because he is so far ahead of the field that I have not caught up with him as yet. Much of it is very logical. It follows the ideas of Homans and Bauer. It was Homans, you will remember, who first was rash enough to suggest the ligation of the femoral vein for this reflux flow in the femoral vein years ago. His slides are beautiful and the result of much effort. I have seen some of his fine results. I am eager to see how they are five years from now. That will be the answer. He must surely be congratulated on his fine work.

Dr. Plimpton is to be congratulated on his excellent discussion of thrombophlebitis. His résumé of the literature is very comprehensive.

In cases of an acute thrombophlebitis of extensive large superficial varicose veins, Dr. Linton prefers to excise the entire inflamed mass and then do a high sapheno-femoral ligation. Most men prefer to put the patient to bed with the application of extensive hot wet packs applied locally. The patient should continue to walk briefly twice daily. Anticoagulants should be given and the prothrombin percentage should be kept down about 35 per cent of normal. One never needs to fear a hemorrhage at that level. I have had two patients in whom the phlebitis extended to the femoroiliac region where I did not use the anticoagulants. Dicumarol is sufficient.

Most men agree with the idea and use of the lumbar sympathetic block for any severe case of deep phlebitis with the resultant edema, cyanosis and cold foot. This should be used early and there should be no delay for several days or weeks. It should be repeated at twenty-four-hour intervals, if needed, to keep the leg and foot warm and dry. Many times I have seen it give much help, even though not used for several weeks after the onset of the phlebitis. In cases having a history of a severe deep phlebitis years before, I often use the block to see if any help could be expected following a sympathectomy. There is no point in using a block for the swollen but warm and dry leg and foot. It will not help. Linton does not advise a sympathectomy for the postphlebitic case. In his experience, the immediate good result has disappeared in two years. I cannot agree with this. Homans has urged a sympathectomy for the old postphlebitic with extensive dermatitis over a cold and clammy lower leg and foot. The ligation of the femoral or popliteal vein may give additional help. Time alone will tell.

I cannot urge too strongly the use of the routine, hot, wet pack for all these cases. Drinker has definitely shown that the hotter the pack to the point of tolerance, the more relaxation of the vessels and the greater the lymphatic drainage. The patient will not get burned if the blankets are wrung dry as with the Kenny pack for poliomyelitis, but they must not be put on with the cloths soaked and sopping wet.

BLUE CROSS PAYS MILLIONS TO HOSPITALS

Nearly a hundred million dollars, representing more than 88 per cent of income, was paid to hospitals by the voluntary, non-profit Blue Cross Plans for care of members during the first quarter of 1950, Richard M. Jones, Chicago, director, Blue Cross Commission of the American Hospital Association, recently announced

From a total income of $109,801,301, the ninety Blue Cross Plans of the United States and Canada paid $96,989,972 for member's care and used only $9,184,564 (8.37 per cent) for operating expenses.

There are more than 38,000,000 persons enrolled in the Blue Cross Plans in the United States and Canada, representing more than 24 per cent of the United States population and 21 per cent of the Canadian people.

In Memoriam

RALPH CRAWE ADAMS

Dr. Ralph C. Adams, a practitioner at Bird Island since 1906, died April 25, 1950. He was seventy years of age.

Dr. Adams was born at Utica, Pennsylvania, June 7, 1879. He was a graduate of Jefferson Medical College, Philadelphia, having received his M.D. in 1906.

Dr. Adams is survived by his wife, Hertha; a son, Jack, who is in the military service; a daughter, Margaret, of Denver, Colorado, and two sisters.

FREDERICK H. ROLLINS

Dr. F. H. Rollins, a prominent practitioner at St. Charles, Minnesota, since 1898, died at Rochester April 27, 1950, after a brief illness.

Dr. Rollins was born near Caledonia, Minnesota, September 30, 1867. He graduated from Rush Medical College in 1897 and practiced for a year in South Dakota before locating at St. Charles.

During World War I, Dr. Rollins served as commanding officer of a convalescent camp base hospital in France. He served as state senator from 1928 to 1934. He was a member of the Masonic Order and of the Order of Eastern Star.

Dr. Rollins is survived by his wife, Mary, two sons, Keith of Chicago and Pat of Minneapolis; one daughter, Mrs. C. D. (Margaret) Thompson of Chicago; and one stepson, Murray Olsen of Rock Rapids, Iowa.

Dr. Rollins was honored at a civic dinner in St. Charles in May, 1947, on the occasion of his fiftieth anniversary as a practicing physician. All his life he was an ardent fisherman and hunter and was most active in a variety of community projects.

CHARLES L. SCOFIELD

Dr. C. L. Scofield of Benson, Minnesota, died April 23, 1950, at the age of eighty-five years. He was born on a farm in Cannon Falls, Minnesota, on April 16, 1865, and in all of the years of his life he showed the results of his early background in his fine attitude towards the people among whom he practiced. He graduated from the University of Iowa in 1886 and began his practice in Saint Paul the same year but in 1890 he moved to the town of Benson where he practiced up to the time when he suffered a cerebral hemorrhage on March 29, 1947.

He had his first office in the Security State Bank building, and in 1900 he moved to the Colby block where he practiced until he built his own office building a number of years after that.

Dr. Scofield was almost a legend in the entire area surrounding Benson. He was truly the old type of country doctor braving the blizzards and winter weather and driving many miles with horse and buggy. No family was too lowly to receive administrations, at his hands, when he was called.

In 1936, when he completed fifty years in the practice of medicine, a testimonial banquet was given at which he was honored for the fine medical practice which he had carried on. Practically everyone who assisted in putting on the dinner had been brought into the world through his help.

His fine attitude towards the public is shown by the fact that during his lifetime he was elected President of the first council; he was a long time member of the School Board; he was for years Chairman of the City Park Board; and was made Chairman of the Charter Commission which drew up the Charter for Benson, making it a city in 1908. At one time he was a member of the volunteer fire department, the manager of the baseball team and for many years was Chairman of the Board of Directors of the Benson Cemetery Association.

He took an active part in the business life of the city. He was at one time President of the Swift County Telephone Company and Security State Bank. He was a member of the Sons of the American Revolution; belonged to the Swift Lodge No. 129, A.F. & A.M.; and the Modern Woodmen of America, the AOUW, the Knights of Pythias, the Isaak Walton League, and the Woodmen of the World. His interest in children and young people in his home town shows him as Chairman of both the District and Local Boy Scout committees for several years. His interest in the early history of Swift County finds him the organizer and President of the Swift County Historical Society. His activities were not limited to the locality in which he lived but we find his honors coming from statewide organizations. In October, 1948, we find him awarded an honorary membership in the Minnesota Public Health Conference for distinguished service in public health. He served several years as president of the Swift County Health Association and helped organize the Minnesota Public Health Association and was its president from 1919 to 1923.

He was a member of the State Tuberculosis Commission and was most active in the various tuberculosis committees in the Minnesota State Medical Association. He was a member of the Kandiyohi-Swift-Meeker Medical Society of which he was secretary for approximately twenty-five years, and a member of the Minnesota State Medical Association of which he was at one time vice president. He was a member of the American Medical Association. He was a Great Northern Railroad surgeon for forty-five years, and in 1936 he received a life membership in the Great Northern Veterans Association. He was a lifetime member of the Pilgrim Congregational Church of Benson, and a member of the building committee which had charge of the erecting of the beautiful church edifice which houses this congregation.

He is survived by his wife, Mrs. Bertha Scofield, together with four grandchildren.

CHARLES L. SCOFIELD

(Continued from Page 630)

Charles L. Scofield was a man of unusual talents, revered by all for his good works, and in his passing, those of us who knew him well feel a deep sense of loss and a keen hope that we may carry on in some manner the fine impressions which he made on the lives of us all. He was the finest type of American citizen, an honor to his profession, and a friend to all—truly a man among men.—B. J. Branton, M.D.

NELS WESTBY

Dr. Nels Westby, well-known and highly esteemed physician of Madison, Minnesota, died April 21, 1950, following a heart attack. He observed his sixty-fourth birthday the day before his death.

Dr. Westby was born April 20, 1886 in Brown County, South Dakota. He attended Augustana Academy in Canton, South Dakota, the University of Minnesota and St. Olaf College, where he graduated in 1909.

On August 29, 1909 he was married to Gusta Locken, and to this union eight children were born.

Dr. Westby received his medical degree from Cornell Medical College in New York in 1913 and served his internship at the Methodist Hospital in Brooklyn, New York.

In January, 1915, he entered into partnership with Dr. W. N. Lee in the Madison Clinic and became chief of staff of Ebenezer Hospital.

Dr. Westby was a member of the Camp Release Medical Society, the Minnesota State Medical Association and the American Medical Association. He was a Fellow of the American College of Surgeons and had recently been appointed to the National Christian Medical Society. He was mayor of Madison, had been a member of the Board of Education School District No. 74 since 1927, and was the present chairman. He was a charter member of the local Kiwanis Club.

Dr. Westby had served as trustee and deacon of the Madison Lutheran church. He served as president of the Brotherhood of the Evangelical Lutheran church in its formative years and had been a member of the Church Council of the Evangelical Lutheran church for the Southern Minnesota District.

He is survived by his wife, Gusta, one son, Norval, and five daughters: Mrs. Aubrey Edmonds of Grand Marais, Minnesota; Mrs. Norris Skogerboe of Brooklyn, New York; Mrs. Gunnar Pederson of Saint Paul; Mrs. Max Barzee of Moro, Oregon; Mrs. William Gualtieri, and Mary Westby, both of Madison.

One of the most persistently discouraging facts about cancer of the lung, is the long interval of ten months that elapses, on the average, between the patient's first visit to the doctor and the time when the diagnosis is made.—Overholt, R. H., and Schmidt, I. C., *New England J. Med.*, Nov., 1949.

The Northwest's Only

Neurologic Center for Civilians

Offers to those afflicted with neurologic disabilities, the best of modern techniques and facilities for the treatment of:

- Hemiplegia
- Multiple sclerosis
- Aphasia or speech disorders
- Paraplegia and other paralyses
- Ataxias

In addition to the highly qualified neurologists and neurosurgeons who staff this center, the staff also includes qualified personnel who have been trained in special therapy, occupational therapy, corrective therapy and physical therapy.

Reports and Announcements

AMERICAN CONGRESS OF PHYSICAL MEDICINE

The American Congress of Physical Medicine will hold its twenty-eighth annual scientific and clinical session August 28, 29, 30, 31 and September 1 at the Hotel Statler, Boston, Massachusetts. All sessions will be open to members of the medical profession in good standing with the American Medical Association. In addition to the scientific sessions, the annual instruction seminars will be held August 28, 29, 30 and 31. These seminars will be offered in two groups. One set of ten lectures will consist of basic subjects and attendance will be limited to physicians. One set of ten lectures will be more general in character and will be open to physicians as well as to therapists, who are registered with the American Registry of Physical Therapy Technicians or the American Occupational Therapy Association. Full information may be obtained by writing to the American Congress of Physical Medicine, 30 North Michigan Avenue, Chicago 2, Illinois.

AMERICAN COLLEGE OF PHYSICIANS

The American College of Physicians will conduct its 32nd Annual Session at St. Louis, Mo., April 9-13, inclusive, 1951. Dr. Ralph Kinsella of St. Louis is the general chairman and will be responsible for local arrangements and for the program of clinics and panel discussions. Dr. William S. Middleton, president of the College, Madison, Wis., will be in charge of the program of morning lectures and afternoon general sessions.

Secretaries of medical societies are especially asked to note these dates and, in arranging meeting dates of their societies, to avoid conflicts with the College meeting for obvious mutual benefits.

AWARD FOR RESEARCH IN INFERTILITY

The American Society for the Study of Sterility offers an annual award of $1,000 known as the Ortho Award, for an outstanding contribution to the subject of infertility and sterility. Competition is open to those in clinical practice as well as individuals whose work is restricted to research in the basic sciences. Essays submitted for the 1951 contest must be received not later than March 1, 1951. The prize essay will appear on the program of the 1951 meeting of the society. For full particulars, address the American Society for the Study of Sterility, 20 Magnolia Terrace, Springfield, Mass.

A HOMELIKE
HAVEN WHERE
ALCOHOLICS
ACHIEVE
INSPIRATION FOR
RECOVERY

200 acres on the shores of beautiful Lake Chisago where gracious living, homelike atmosphere and understanding companionship contribute to successful rehabilitation.

HAZELDEN FOUNDATION

The constructive thinking of a group of Twin Cities men seeking a new approach to the problem of alcoholism resulted in the organization of the Hazelden Foundation. Some of the founders are themselves men who have recovered from alcoholism through the proved program of Alcoholics Anonymous. Their true understanding of the problem has resulted in the treatment procedures used at the Hazelden Foundation.

COURSE IN POSTGRADUATE GASTROENTEROLOGY

The National Gastroenterological Association announces that its course in postgraduate gastroenterology will be given at the Hotel Statler in New York City on October 12, 13, 14.

The course, which will again be under the personal direction of Dr. Owen H. Wangensteen, professor of surgery, University of Minnesota Medical School, will cover the following subjects: diseases of the mouth, diseases of the esophagus, peptic ulcer diseases of the stomach, diseases of the pancreas, cholecystic disease, psychosomatic aspects of gastrointestinal disease, disease of the liver, diseases of the colon and rectum, and other miscellaneous subjects including pathology and physiology, radiology, gastroscopy, et cetera.

The distinguished faculty for the course has been chosen from medical schools in New York City as well as out of town.

For further information and enrollment write to the National Gastroenterological Association, Dept. GSJ, 1819 Broadway, New York 23, N. Y.

PLASTIC SURGERY AWARD

The Foundation of the American Society of Plastic and Reconstructive Surgery is offering awards of $300 (first prize) and $200 (second prize) and a certificate of merit for essays on some original unpublished subject in plastic surgery.

Competition is limited to residents in plastic surgery in recognized hospitals and to plastic surgeon who have been in such specific practice for not mor than five years. The first-prize essay will appear o the program of the forthcoming annual meeting o the American Society of Plastic and Reconstructiv Surgery, to be held in Mexico City November 2 through 29, 1950. Essays must be received befor August 15, 1950.

Full information can be obtained from the secretary, Dr. Clarence R. Straatsma, 66 East 79th Street New York, N. Y.

FELLOWSHIP IN MEDICINE AVAILABLE

The American College of Physicians announces that a limited number of fellowships in medicine will be available from July 1, 1951 to June 30, 1952. These fellowships are designed to provide an opportunity for research training either in the basic medical sciences or in the application of these sciences to clinical investigation. They are for the benefit of physicians who are in the early stages of their preparation for a teaching and investigative career in internal medicine. Assurance must be provided that the applicant will be acceptable in the laboratory or clinic of his choice and that he will be provided with the facilities necessary for the proper pursuit of his work.

The stipend will be from $2,200 to $3,200. Application forms will be supplied on request to the Amer-

Theocalcin

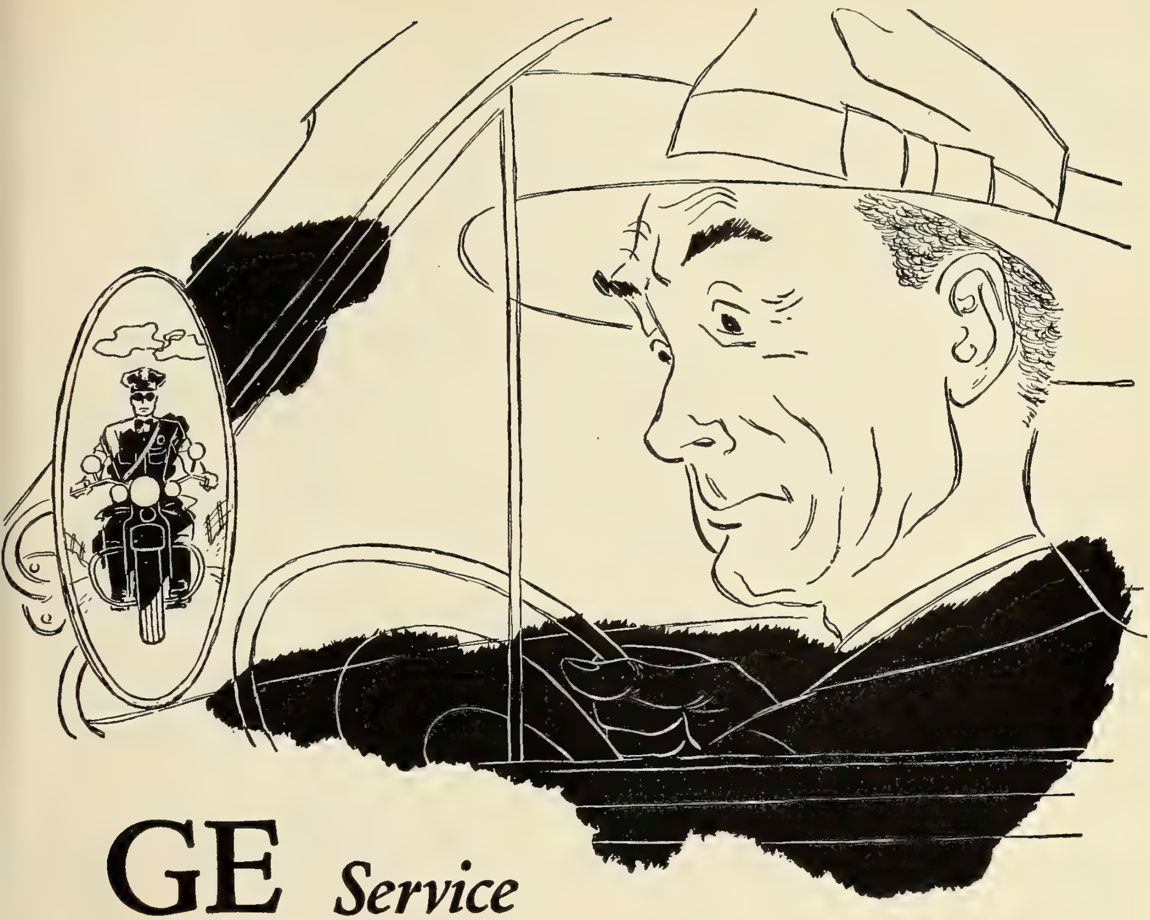
In Congestive Heart Failure

For the reduction of edema, to diminish dyspnoea and to strengthen heart action, prescribe Theocalcin, beginning with 2 or 3 tablets t. i. d., with meals. After relief is obtained, the comfort of the patient may be continued with smaller doses. Well tolerated.

Theocalcin, brand of theobromine-calcium salicylate,
Trade Mark reg. U. S. Pat. Off.

Available in 7½ grain tablets and in powder form.

Bilhuber-Knoll Corp. Orange, N. J.



GE *Service in a "pinch"*

It could happen to you; that "now-what-have-I-done" feeling that raced through the GE salesman's mind as the Lynchburg, Virginia, officer curbed him with screaming siren.

But read the story behind it. An emergency service call came in from Lynchburg to the Richmond office. The GE salesman in that area was enroute to take care of a previous call which took him through Lynchburg. GE immediately phoned the Chief of Police in Lynchburg and enlisted his cooperation in stopping the salesman as he entered town. Needless to add, emergency service was soon effected and a Lynchburg hospital's X-ray equipment was back in service in minutes!

This story is typical of the hundreds of documented GE service reports in our files. A service which proudly lends a new, broader conception to the guarantee that stands back of every GE installation.

MISSISSIPPI VALLEY ESSAY CONTEST

The tenth annual essay contest of the Mississippi Valley Medical Society which provides a cash prize of $100, a gold medal and a certificate of award for the best unpublished essay on any subject of general medical interest (including medical economics and education) and practical value to the general practitioner of medicine will again be held in 1950. The winner will be invited to present his contribution before the fifteenth annual meeting of the Mississippi Valley Medical Society in Springfield in September, 1950. Further details may be obtained from Dr. Harold Swanberg, Secretary, 209 W.C.U. Building, Quincy, Illinois.

MINNESOTA SOCIETY OF INTERNAL MEDICINE

The spring meeting of the Minnesota Society of Internal Medicine was held in Duluth on May 27. Program chairman for the event was Dr. Paul G. Boman, Duluth. Eighteen papers on various topics in internal medicine were presented during the one-day session.

MINNESOTA SURGICAL SOCIETY

The Minnesota Surgical Society held its annual meeting in Rochester on May 12. Clinics in various phases of surgery were held at Colonial, St. Mary's, Kahler and Worrall Hospitals in the morning. The afternoon session consisted of presentation of papers.

Elected president of the society was Dr. Willard D. White, Minneapolis. Other officers elected include Dr. E. Starr Judd, Jr., Rochester, vice president, and Dr. M. G. Gillespie, Duluth, secretary-treasurer.

BROWN-REDWOOD-WATONWAN COUNTY SOCIETY

A talk on the Minnesota medical publicity program was a feature of the annual meeting of the Brown-Redwood-Watonwan County Medical Society held in New Ulm on May 18. Dr. E. J. Nielson, Mankato, discussed the publicity program prepared by the Minnesota State Medical Association. A discussion was also held on the possibilities of forming blood banks in the various cities of Brown County.

SOUTHWESTERN MINNESOTA SOCIETY

The regular monthly meeting of the Southwestern Minnesota Medical Society was held in Pipestone on May 8. Principal speaker at the meeting was Dr. Clarence Dennis, professor of surgery at the University of Minnesota, who spoke on "The Acute Abdomen."

(Continued on Page 640)

Doctor . . .

Here are two great Spot Tests that simplify urinalysis

GALATEST

The simplest, fastest urine sugar test known.

ACETONE TEST

(DENCO)

For the rapid detection of Acetone in urine or in blood plasma.

A LITTLE POWDER

A LITTLE URINE

COLOR REACTION IMMEDIATELY

Galatest and Acetone Test (Denco) . . . Spot Tests that require no special laboratory equipment, liquid reagents, or external sources of heat. One or two drops of the specimen to be tested are dropped upon a little of the powder and a color reaction occurs immediately if acetone or reducing sugar is present. False positive reactions do not occur. Because of the simple technique required, error resulting from faulty procedure is eliminated. Both tests are ideally suited for office use, laboratory, bedside, and "mass-testing." Millions of individual tests for urine sugar were carried out in Armed Forces induction and separation centers, and in Diabetes Detection Drives.

The speed, accuracy and economy of Galatest and Acetone Test (Denco) have been well established. Diabetics are easily taught the simple technique. Acetone Test (Denco) may also be used for the detection of blood plasma acetone.

Write for descriptive literature.

. . . in all cases of coronary thrombosis

Reduced mortality and morbidity have led the American Heart Association study group to recommend the use of anticoagulants as part of basic therapy "in all cases of coronary thrombosis with myocardial infarction."[1]

Long-acting Depo*-Heparin preparations meet the clinical requirements for prompt and readily controlled anticoagulant effects in the treatment of coronary heart disease. Depo-Heparin Sodium, with or without vasoconstrictors, provides the natural anticoagulant in a gelatin and dextrose vehicle to produce anticoagulant effects for 24 hours or longer with a single injection.

Methods of extraction, purification and assay have been so perfected by recent investigations of Upjohn research workers that Depo-Heparin is now available in full clinical supply.

SOUTHWESTERN MINNESOTA SOCIETY

(Continued from Page 638)

During the business session the society's executive committee was instructed to consider the formation of a grievance committee to review criticism and complaints which might arise concerning medical care.

WASHINGTON COUNTY SOCIETY

The Washington County Medical Society held its regular monthly meeting at Forest Lake on May 9. At the meeting, which was for business only, members considered requests from the Social Welfare Department of the State of Minnesota and acted on the recommendations of the Committee on Public Education of the Minnesota State Medical Association concerning medical publicity.

A special meeting with the Welfare Board was planned for June 6 at Stillwater to consider fees.

The "forty education posters," recommended at the medical-press conference in Saint Paul on April 21, were the subject of a lively discussion that became fairly warm at times. Representatives of the four county newspapers also took part in the discussion. The final result: it was moved that all forty posters be run by the four newspapers in the county, to be paid for by members of the county medical society.

The society members also voted to establish a grievance committee, to be administered by the advisory committee.

Woman's Auxiliary

AUXILIARY HEARS NURSE RECRUITMENT PROGRAM

The Auxiliary of the Southwestern Minnesota Medical Society met at the home of Dr. and Mrs. F. L. Schade in Worthington on April 24 for a program on nurse recruitment.

Guest speaker was Marlene Erickson of Northwestern Hospital, Minneapolis. She spoke on methods of nurse recruitment through the local schools. Miss Erickson was introduced by Mrs. Marion Neilson, program chairman.

Mrs. David Halpern, Brewster, discussed what local communities and the medical auxiliary can do to encourage girls to enter the profession.

Dorothy Petsch, Worthington Hospital superintendent, told of plans for the nurse procurement program at the Worthington high school career day.

Special guests at the meeting were the new student nurses from Fairview Hospital in Minneapolis. The four girls went on duty in April. They are participating in the rural nursing affiliation program conducted through a local hospital.

The girls are Delores and Doris Johnson, twin sisters from Litchfield; Aida Hoff of Grantsburg, Wisconsin, and Erma Hellickson of Scobey, Montana.

Don't go hog wild—

on your ACCOUNTS RECEIVABLE

Usually the last one to be paid is the family doctor, and very often, no attention is given by him to the very important matter of commencing collection work *promptly after due date.* Too many doctors are going "hog wild" on this point and fail to realize its significance. Though startling as they may be, the figures shown in the following table are the factual result of authoritative studies, and they apply to the doctor as well as to the businessman.

COLLECTIBILITY OF ACCOUNTS—BASED ON AGE

Accounts	60	days	past due are	93%	collectible.
Accounts	90	days	past due are	85%	collectible.
Accounts	6	months	past due are	70%	collectible.
Accounts	1	year	past due are	40%	collectible.
Accounts	2	years	past due are	25%	collectible.
Accounts	3	years	past due are	18%	collectible.
Accounts	5	years	past due are practically lost.		

THE OUTLOOK ISN'T BRIGHT. More business and professional men look for lower profits than hope for higher earnings this year. That's because of lower prices and higher costs. Proper credit control is more important today than at any time since the war. Jobless at present are at a postwar high of 4½ million. Unemployment is likely to prove more of a headache than inflation.

NOW IS THE TIME to go after those "Receivables." You can't afford to let even one of them get away when it's so easy to get your money by using our tested and proven plan. This system has the "velvet touch" with the "dynamite punch." Your money is paid directly to you and you retain your debtor's good will. Get started now by using the coupon below or just sign and return for more information.

Captain Eugene V. Meyerding, M.C., U.S.A.F., son of Dr. and Mrs. E. A. Meyerding of Saint Paul, was married on May 19 to Patricia Elliot Lord, daughter of Colonel and Mrs. Wilbur Storn Elliot of Honolulu. Captain Meyerding is surgical resident at the Triplet General Hospital in Honolulu. He is a graduate of St. Thomas Military Academy and the University of Minnesota Medical School.

* * *

Dr. Alan Challman, Minneapolis, was scheduled to return on June 26 from a six-week tour of Army hospitals in Germany and Austria. He was selected by the Surgeon General of the Army to make the visits, which were for purposes of teaching and consultation.

* * *

Four physicians, comprising the **Litchfield Clinic,** are now conducting their practices in a newly constructed clinic building in Litchfield. The physicians are Dr. H. E. Wilmot, Dr. C. A. Wilmot, Dr. D. E. Dille and Dr. W. A. Chadbourn.

Their new clinic building, which was completed early this spring, is a one-story structure of modern design and construction. It houses four physicians' suites, each one consisting of an office and two treatment rooms, plus a laboratory, x-ray room, operating room, business office, and pharmacy. The building measures 55 by 66 feet, has a full basement for storage and other facilities, and is designed so that the flat roof can be flooded with a layer of water for cooling in the summer.

An open house, at which the clinic's facilities were open for public inspection, was held on April 1 and was attended by a large number of local residents.

* * *

Members of the Scott-Carver County Medical Society heard an address by **Dr. Edward T. Evans,** Minneapolis, at their meeting on April 18. Dr. Evans presented an illustrated lecture on the differential diagnosis of back pains, stressing the diagnosis of slipped intervertebral disc.

* * *

Dr. Paul Carpenter, formerly of Kansas City, Kansas, has become a staff member of the Oliver Clinic in Graceville. He began his duties at the clinic on April 3.

Dr. Gordon R. Kamman, Saint Paul, has been named deputy commissioner of mental health in Minnesota by Dr. Ralph Rossen, commissioner. **Dr. Lawrence R. Gowan,** Duluth, has been appointed supervisor of the consultative services. Both men will serve on a part-time basis while continuing the private practice of pyschiatry.

* * *

Dr. Clyde A. Undine, Minneapolis, attended the convention of the American College of Physicians in Boston, Massachusetts, April 17 through 21.

* * *

It was announced in May that **Dr. Robert M. Lundblad,** Duluth, planned to begin the practice of medicine in Clara City on July 1. Dr. Lundblad is a graduate of the University of Minnesota Medical School.

* * *

Dr. Andrew Sinamark, Hibbing, was a member of a three-man panel discussion on socialized medicine at a meeting of the Parent-Teachers' Association in Nashwauk on May 23.

* * *

Thirty-nine former fellows and residents of **Dr. Henry E. Michelson** gathered for a testimonial dinner to him at the Minneapolis Club on May 5. The guest list included dermatologists from Chicago, Cincinnati and the Mayo Clinic. Dr. Michelson had completed twenty-five years of service as chief of the division of dermatology at the University of Minnesota. He was presented with a silver service at the dinner, which was arranged by Drs. Laymon, Lynch, Madden and Rusten.

Previously, on April 15, Dr. Michelson was elected president of the American Board of Dermatology and Syphilology at a meeting held in Washington, D. C.

* * *

Dr. S. A. Slater, superintendent of the Southwestern Minnesota Sanatorium, was re-elected to the board of directors of the National Tuberculosis Association at a meeting in Washington, D. C., on April 28 and 29. Dr. Slater's new term as a director will be his twelfth.

* * *

On May 6, **Dr. Joseph Kurtin** was married to Miss Ruth Witkowski in Cudahy, Wisconsin. Dr. Kurtin is now practicing medicine in Blooming Prairie with his brother, Dr. H. J. Kurtin.

* * *

Dr. Albert J. Schroeder was guest pediatric speaker at a meeting of the American Society of Dentistry for Children on April 18. The meeting was held in Coffman Memorial Union at the University of Minnesota.

HOSPITAL NEWS

At a special meeting of the Gaylord Community Club on April 27, a resolution was passed to construct during the summer a municipal hospital for **Gaylord** and the surrounding area. The quick action was prompted by an announcement by Dr. D. C. Olson that he planned to close his hospital permanently. Dr. Olson agreed to keep his hospital open until the new hospital was completed, probably this coming fall.

* * *

St. Lucas Deaconness Hospital, Faribault.—Dr. Paul F. Meyer, Faribault, was elected president of the St. Lucas Deaconness Hospital medical staff at a meeting held on May 9. Other officers elected include Dr. C. A. Rohrer, Waterviller, vice presiden; Dr. J. J. Kolars, Faribault, secretary, and Dr. F. R. Huxley, Faribault, member-at-large on the executive committee.

* * *

Kanabec Hospital, Mora—Dr. C. S. Bossert of Mora was elected chief-of-staff of the Kanabec Hospital at an organizational meeting of the staff on May 11.

* * *

Dedication of the new **Louis Weiner Memorial Hospital** in Marshall took place on May 25. When completely furnished, the new hospital will have approximately fifty beds, 12 bassinettes and four cribs.

The dedication ceremonies included a presentation of the hospital staff and an address by Governor Luther W. Youngdahl.

BLUE CROSS-BLUE SHIELD NEWS—June, 1950

Blue Shield enrollment more than doubled in or year's time. On March 30 of this year there we 315,226 Minnesotans enrolled in Blue Shield compare with 151,711 enrolled on March 30 a year ago. Enrol ment in March was especially high with 22,771 Minn sotans added to Blue Shield rolls; of these, 12,367 ar non-group subscribers whose contracts went into effe March 1.

Also more than doubled are the Blue Shield benefit subscribers received during the first quarter of this yea compared with the same period in 1949. This year, Blu Shields benefits amounted to $411,133 during the firs quarter compared with $191,116 subscribers receive in Blue Shield benefits during this same three-montl period in 1949. Payments to doctors during March fo services to Blue Shield subscribers totalled $181,62 which is $49,380 more than the payments made t doctors during February.

Of the total 10,289 claims submitted during the firs quarter of this year, representing 12,679 medical surgical services to Blue Shield subscribers, 79 per cen or 8,132 claims were for Blue Shield services subscriber received in hospitals; 20.6 per cent or 2,118 claims wer for services received in doctors' offices, and .4 per cen or 39 claims were for Blue Shield services subscriber received in homes.

Blue Shield benefits for surgical procedures during this three-month period totalled $255,174.53. Of these surgical procedures, benefits for appendectomies were

MINNESOTA STATE BOARD OF MEDICAL EXAMINER

Minneapolis Man Pleads Guilty

(Continued from Page 617)

an information charging him with the crime of swindling. Judge Larson stayed the sentence and place the defendant on probation for five years.

Catterson, who has no medical education of an kind, obtained $100 from a north Minneapolis famil on or about June 24, 1949. Catterson had offered t perform an abortion but disappeared after obtaining th money. Catterson was not located until April 7, 1950 at which time he was placed under arrest. Catterson readily admitted obtaining the $100, but stated that he never intended to do an abortion and had used those representations for the purpose of obtaining money Nevertheless, Minneapolis police officers found a speculum and a syringe in Catterson's room. Catterson als admitted that he had two or three catheters in his possession, but these were not found.

Catterson stated to the Court that he was born in 1899; that he had been married and divorced four times. Catterson also admitted having a previous conviction in Lancaster County, Pennsylvania, for the crime of adultery. Judge Larson, in sentencing the defendant, told him that the Court was not optimistic about Catterson making good on probation; nevertheless, it was the opinion of every one concerned, that in view of the fact that twenty-four years had elapsed between Catterson's first conviction and his present violation of the law, an opportunity should be given him to demonstrate that he could comply with the laws of the State of Minnesota.

IT'S YOUR BUSINESS

IT'S AMAZING the number of professional people who ignore the law of averages hoping that their income will continue uninterrupted.

THE RECORD in this office shows that during last year $49,077.91 was paid to one out of eight of the doctors in the Minnesota State Medical Association.

IT'S YOUR BUSINESS!

WITH THAT probability facing you in 1950, it's sage advice to suggest that you apply for the Minnesota State Medical Association plan of income protection.

DELAY OFFERS NO ADVANTAGE.

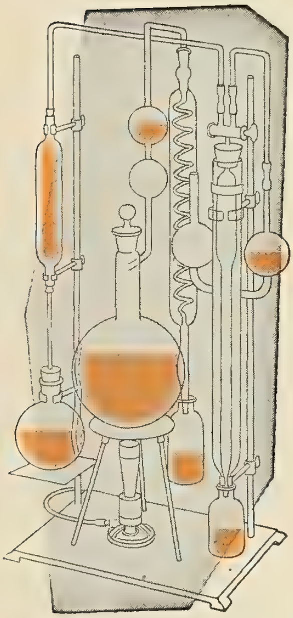
AUREO-
MYCIN

in Surgical and Other Infections

AUREOMYCIN



Surgeons are now generally coming to the conclusion that the use of aureomycin preoperatively and postoperatively in all cases is worthwhile insurance against infection. This is particularly true in infections involving the peritoneum.

Aureomycin has also been found effective for the control of the following infections: African tick-bite fever, acute amebiasis, bacterial and virus-like infections of the eye, bacteroides septicemia, boutonneuse fever, acute brucellosis, Gram-positive infections (including those caused by streptococci, staphylococci, and pneumococci), Gram-negative infections (including those caused by the coli-aerogenes group), granuloma inguinale, *H. influenzae* infections, lymphogranuloma venereum, primary atypical pneumonia, psittacosis (parrot fever), Q fever, rickettsialpox, Rocky Mountain spotted fever, subacute bacterial endocarditis resistant to penicillin, tularemia and typhus.

Capsules: Bottles of 25, 50 mg. each capsule.
Bottles of 16, 250 mg. each capsule.

Ophthalmic: Vials of 25 mg. with dropper; solution prepared by adding 5 cc. of distilled water.

sequence in biliary tract surgery

preoperatively-Decholin

brand of dehydrocholic acid stimulates an abundant flow of thin bile, helping to "clear the arena" for surgery by the removal of inspissated bile, mucus, small stones and other accumulations from the choledochus. This powerful hydrocholeretic action also produces functional distension of the gallbladder and ducts, aiding in identification and surgical procedure.

postoperatively-Decholin

provides an effective means of flushing out the biliary tract. Used together with antispasmodics such as atropine and nitroglycerin, *Decholin* helps to remove blood clots, residual debris and hidden, small calculi. This method, recently reemphasized by Best,[1] is useful with or without T tube drainage. In reflex biliary stasis, *Decholin* serves to prompt an adequate secretion of bile.

For more rapid and intense hydrocholeresis, *Decholin Sodium*, brand of sodium dehydrocholate, is given intravenously, followed by a course of *Decholin* tablets.

Decholin

brand of dehydrocholic acid

Decholin (brand of dehydrocholic acid) Tablets of 3¾ grains, in bottles of 25, 100, 500 and 1000.

Decholin Sodium (brand of sodium dehydrocholate) 20% solution, in ampuls of 3 cc., 5 cc. and 10 cc., boxes of 3 and 20.

CHRONIC ASTHMATIC

. . . . Back in Executive Harness

● Many chronic asthmatics have been restored to activity—and maintained that condition—by controlling attacks with NORISODRINE powder inhalation.

Using the Aerohalor®, Abbott's powder inhaler, and a cartridge containing NORISODRINE POWDER, the patient inhales three or four times and the bronchospasm usually ends quickly. This take-it-with-you therapy is effective against mild as well as severe forms of asthma.

Proved by clinical investigation[1,2], NORISODRINE is a bronchodilator with relatively low toxicity. Few side-effects result when the drug is properly administered and these are usually minor. Before prescribing NORISODRINE, however, please write to Abbott Laboratories, North Chicago, Illinois, for literature. This tells how to establish individual dosage and precautions to be taken.

NORISODRINE Sulfate powder 10% and 25% is supplied in multiple-dose Aerohalor* Cartridges, with rubber caps, three to an air-tight vial. The Aerohalor is prescribed separately.

ALWAYS READY FOR USE WHEN THE NEED ARISES

"The ... estrogen preferred by us is 'Premarin,' a mixture of conjugated estrogens, the principal one of which is estrone sulfate."

Hamblen, E. C.: North Carolina M. J. 7:533 (Oct.) 1946.

In treating the menopausal syndrome with "Premarin," Perloff* reports that "Ninety-five and eight tenths per cent of patients treated with 3.75 mg. or less daily obtained complete relief of symptoms"; also, "General tonic effects were noteworthy and the greatest percentage of patients who expressed clear-cut preferences for any drug designated 'Premarin.'"

Thus, the sense of "well-being" usually imparted represents a "plus" in "Premarin" therapy which not only gratifies the patient but is conducive to a highly satisfactory patient-doctor relationship.

Four potencies of "Premarin" permit flexibility of dosage: 2.5 mg., 1.25 mg., 0.625 mg. and 0.3 mg. tablets; also in liquid form, 0.625 mg. in each 4 cc. (1 teaspoonful).

*Perloff, W. H.: Am. J. Obst. & Gynec. 58:684 (Oct.) 1949.

"PREMARIN"®

While sodium estrone sulfate is the principal estrogen in "Premarin," other equine estrogens...estradiol, equilin, equilenin, hippulin...are probably also present in varying amounts as water-soluble conjugates.

Estrogenic Substances (water-soluble) also known as Conjugated Estrogens (equine)

boxing the compass in infant nutrition

North, East, South, West—for every type of nutritional requirement, there is a Borden prescription product scientifically designed to meet the problem.

Biolac, Borden's improved, evaporated-type liquid modified milk, provides for all the known nutritional needs of early infancy except vitamin C.

Dryco, a high-protein, low-fat powdered milk, serves as a valuable food in itself and as a versatile base assuring ample protein intake plus vitamins A and D. **Mull-Soy** is the answer to milk allergies—an emulsified hypo-allergenic soy food approximating milk. **Gerilac**, a spray-dried whole milk and skim milk powder, supplies elderly patients with high quality protein, calcium and iron, and also vitamins A, D, B and C. **Beta Lactose** promotes normal intestinal flora and acidity when used as a carbohydrate modifier. **Klim** is powdered pasteurized whole milk, spray-dried for rapid solubility, convenient in hot climates and during travel.

These Borden products conform to the requirements of the Council on Foods and Nutrition and the Advertising Committee of the American Medical Association and are available only in pharmacies. We welcome inquiries from physicians. Write for professional literature and attractive practical Recipe Books.

"COMFORT ZONE"

WITH

KISCO CIRCULAIR

The "Successor to the Fan"

REG. NO. 395746

Remember the sweltering, sultry days last summer when the thermometer was hovering around the 100° mark? They are almost here again and that brings up the question of what you can do to make your patients more comfortable this summer. They will appreciate a cool, restful reception room, and you will finish the day feeling more rested and refreshed with a **KISCO CIRCULAIR** in your office.

KISCO CIRCULAIR provides refreshing cool comfort during the sweltering heat of summer by picking up the cool low-level air and circulating it outward in every direction into the breathing zone without dangerous drafts or noisy blasts. Every **KISCO CIRCULAIR** is enclosed for safe use where children are present.

If you have a problem of exhausting hot, stale air from the sick room, your office or reception room, a Portable Kisco Window Fan will solve it for you. There are 6 Models in 3 Sizes—12, 16 and 20"—to choose from, and every model is fully guaranteed by **KISCO** and approved by Underwriters' Laboratories, Inc. Adjustable to most standard windows, quickly and easily installed, enclosed by a rugged, closely woven safety guard for complete safety.

TRIMETON

The Protein-Rich Breakfast and Morning Stamina

Extensive studies* by the Bureau of Human Nutrition have established that breakfasts rich in protein and supplying 500 to 700 calories, effectively promote a sense of well-being, ward off fatigue, and sustain blood sugar levels at normal values for the entire morning postbreakfast period.

These physiologic advantages are related mainly to the protein content rather than to the caloric content of the breakfast. In fact, when isocaloric breakfasts were compared, those with the higher amounts of protein led to the greatest beneficial effects. Breakfasts providing the lower quantities of protein (7 Gm., 9 Gm., 16 Gm., and 17 Gm. respectively) produced a rapid rise in the blood sugar level and a return to normal during the next three hours. Breakfasts providing more protein (22 Gm. and 25 Gm. respectively) produced a maximal blood sugar rise which was lower than that following the breakfasts of lower protein content, but the return to normal was delayed beyond the three hour period.

The subjects on the higher protein breakfasts "reported a prolonged sense of well-being and satisfaction." The findings indicated that the beneficial effects of the high protein breakfast on the blood sugar level may extend into the afternoon.

Meat, man's preferred protein food, is a particularly desirable means of increasing the protein contribution of breakfast. The many breakfast meats available are not only temptingly delicious and add measurably to the gustatory appeal and variety of the morning meal, but they also provide biologically complete protein, B-complex vitamins, and essential minerals. *Meat for breakfast, a time-honored American custom, is sound nutritional practice.*

NOTICE
KWITTEN THE CREDIT BIZNEZZ TILL I GET MY OUTZ IN!

This cross roads storekeeper is 50% right. He should get his "outs" in as he says, but refusing credit to his customers is 100% wrong.

There is a better way to go after your "Accounts Receivable" and you can still enjoy the benefits of a credit business. The matter of commencing collection work **promptly after due date** is the important thing.

Do you know that your net profit has been lost on accounts 90 days delinquent or earlier? Do you know that your gross margin has been lost on accounts delinquent 6 months, which means a loss equal to the cost of doing business?

Proper credit control is far more important to you today than it was in the days of the cross roads storekeeper. He settled many accounts by accepting a half-a-hog, a few bushels of spuds or some chickens, but you can't do business that way now. You've got to see the color of your debtor's money, and what's more, get a hold of it if he owes it to you.

We have just the plan for getting those past due accounts in. It's all done efficiently and courteously. Our system is guaranteed and endorsed by trade associations all over the country. Thousands of business and professional men are using our clean cut, potent and economical service with very successful results. Best of all, it requires no effort on your part; we do all the work and the money is paid directly to you. You retain your customers good will, too.

Why don't you start now getting your "outs" in. Make up a list of your past due accounts and mail it in, together with the coupon below and your check for the service you desire. If you want more information first, just sign your name and address to the coupon and shoot it in. There's no obligation.

THE EMOTIONAL PROBLEMS OF THE CHRONICALLY ILL

GEORGE SASLOW, M.D.
St. Louis, Missouri

AT the present time (and I say at the present time because things may change in the next ten years about tuberculosis), we must regard tuberculosis as a chronic disease requiring treatment for an unknown number of months or years. It is a chronic disease, the treatment of which usually requires a number of different forms of therapy: treatment at home, involving bed rest and the avoidance of contagion for others; treatment in a sanatorium where there is bed rest and the same care about contagion, and where there are also surgical procedures such as collapse therapy and thoracoplasty; and where there may be used, in either place, antibiotics like streptomycin.

Different kinds of treatment may have to be used from time to time in the course of a patient's tuberculosis treatment. The patient has to be prepared for these changes. It may be that one kind of treatment has not been beneficial, or that it must be continued longer. Perhaps he must shift temporarily to some other more drastic treatment.

All of these changes involve a high degree of co-operation on the part of the patient. To make matters worse there is no quick, easy or sure cure for tuberculosis and out-patients soon get to know that. Furthermore, bed rest (that is, an extremely low level of activity for a long period of time) is still the major reliance of therapy. To make matters still more difficult for the patient with this illness, he soon learns or he witnesses, in other patients, that he may be subject to unpredictable relapses. For him to be successfully treated under these conditions it is most important that the patient have the capacity to sustain co-operation with the physician and other persons who are part of the medical team. In this regard, he has to sustain co-operation with medical personnel for a long period of time in diverse kinds of therapy and with possibly various kinds of discouragement and no certain result. He is thus in the same situation as patients with other chronic, intermittent diseases, such as diabetes. Here, where we have an important therapeutic chemical substance, insulin, exactly the same problems are found. In the cases of persons with structural heart disease, such as rheumatic fever, we have the same problems of ups and downs, of different kinds of treatments, from limitation of work to surgery. People with epilepsy must be followed all their lives. Thus, in the treatment of various chronic, intermittent diseases, there are common general problems.

Apparently it is extremely difficult for people with tuberculosis (as with other diseases) to sustain a co-operative relationship with medical persons or a medical team. This difficulty is highlighted by some recent studies, published in 1948. I refer to the issue of the Public Health Report, November 5, 1948, Tuberculosis Control Issue, Number 33, in which the main article "Irregular Discharge of the Tuberculous" covered the problem of irregular discharge, meaning discharge before the person had received maximal benefit from hospital treatment.

In this article there is the statement that over 50 per cent of tuberculous patients in Veterans Administration sanatoria left before they had

---

Tuberculosis Lecture given at a meeting of Third District, Minnesota Nurses Association, November 9, 1949.

Dr. Saslow is Associate Professor of Psychiatry, Washington University School of Medicine, Psychiatric Consultant to the Student Health Service of Washington University, and Director of the Division of Psychosomatic Medicine.

received maximal benefits from hospitalization. More than half the patients in these VA tuberculosis sanatoria failed to receive what they should have from modern medical knowledge. You might think that this might have had something special to do with the way VA sanatoria are operated but study of other hospitals showed it had nothing whatever to do with the way VA hospitals, as such, are operated. A survey was made of this sort of thing in hospitals throughout the country including public and private sanatoria, of various sizes, and in diverse locations. In one such survey made some years ago of a sanatorium in Tennessee, for example, 70 per cent of the hospitalized tuberculous patients left against medical advice, that is, before they received maximum benefits. So the figures run for over a hundred sanatoria throughout the country which have been studied during the past ten or fifteen years, right up to the present time. Taking all the figures together, from about 30 to over 70 per cent of hospitalized tuberculosis patients do not complete their course of treatment. A fair number of these are dead within a year, having in the meantime spread infection to an unknown number of other persons in that year. It must, therefore, be very difficult to sustain the kind of co-operation which I mentioned, and from that point of view, I don't think it is exaggerating to say that tuberculosis had best be regarded not only as a disease of the infected parts of the body (the lungs for example), but also as a disorder involving the entire personality. Unless the person is treated in a certain way, we cannot give him the benefits of our best medical and surgical knowledge.

From this point of view, which will be basic to the rest of what I have to say, I shall discuss certain points in the course of our professional contacts with a tuberculosus patient. If we have a greater sensitiveness to him as a person, we may help him sustain the necessary co-operation with a medical team. There are ways of helping a patient sustain such co-operation. The knowledge and skill to secure this co-operation are not widely enough spread throughout the medical team. We can bring out this kind of knowledge by discussing how to help a tuberculous patient: (1) at the time of diagnosis, when the patient is told he has the disease, (2) at the time when he is to have active therapy, as in a sanatorium, and (3) at the time when he is ready for discharge and ready to resume ordinary life.

Let's take the first point, the time of diagnosis. Consider what happens at this time, which, if we consider the patient as a person, we might turn to his advantage. It is important to remember that his inner ability to stand up under this strain is decreased by his illness.

The patient comes to see a physician for a general examination because he hasn't been feeling quite up to par, his complaints are vague, and his work efficiency has fallen off. Perhaps he tires a little more easily but that is about as much as he knows. Let us suppose next that the examinations, which are necessary, are done, the physician picks out some clues, perhaps a chest x-ray film indicates that tuberculosis must be considered seriously. Then suppose he finds tubercle bacilli in the sputum or in the gastric washings. The x-ray reading indicates tuberculosis without question. The physician is certain of the diagnosis. This is completely unsuspected by the patient up to this point.

Now the physician has to communicate the seriousness of the condition to the patient. And in giving the patient the diagnosis, no matter how he does it, he must make the seriousness of the illness understood. The patient reacts in one of a number of ways to which the physician can pay much or little attention. The patient may show no reaction at all, may look apathetic, just listen and show nothing. It is incredible, I think, for all of us who have seen patients with tuberculosis, to believe that they really feel nothing.

One's guess is that when a patient shows apathy on receiving such serious news, there is something about it that is so painful that he is stunned by the words, just as some persons suffering the bereavement of a close relative may show no outward emotion whatever. The very person that was expected to be most disturbed by the death of a father, mother, a husband or wife, may register no reaction. It is perfectly possible for him to be so startled by serious news as to appear as though nothing had happened. The physician, after he tells the tuberculosis patient of his diagnosis, may go on to explain about treatment. He may talk for 15 or 20 minutes. He may find to his surprise, some days or weeks later, or when some one else talks to the patient, that a quite intelligent patient has remembered nothing whatsoever of what has been said to him.

There are many variations in reaction to emotional shock. One may simply remain stunned and unaware. There may be the reaction of crying, or with men (who aren't supposed to cry in our society except in the presence of their mothers), there may be tears in the eyes. Other reactions include intense fear which the physician usually describes as shock. The physician may pay no attention to these reactions, or absence of reactions, but may keep on explaining what the disease is and what will happen to his patient.

The patient, in his intense anxiety, may assert that the physician is wrong in his diagnosis, may go on telling himself that he can't possibly have the disease, and his thoughts may follow one of various common courses. Some patients may never want to see another physician again and, in consequence, become seriously ill, or report to a hospital too late, or may die. Others may go from doctor to doctor, hoping to find one who will tell them they do not have tuberculosis. If there is any question about the diagnosis, or if the physician does not have time to discuss the findings or make a careful study, these patients will seek assurance from persons who are not physicians, who are willing to differ.

Another kind of reaction that is not so common, for some reason or other, is the sudden outburst of anger on the part of the patient, against the person whom he blames for having infected him—some one in the neighborhood or in the family, perhaps, who is known to have had tuberculosis or is thought to have had the disease

Many other things may take place in the thinking and feeling of patients at the time the diagnosis is communicated to them. Some people may think that having tuberculosis is punishment for personal misbehavior. They reason: "I stole something, I was unfaithful to my wife or my husband, or I acted too arrogantly. This, then, is my punishment." Since some patients regard this news as being a punishment for something and since no one likes to be sentenced to jail, talk about being in a sanatorium for a year to such a person is the equivalent of a jail sentence. Such a person may decide, "before I go to jail I'll have my last fling and have a fine time night after night."

In one such instance, reported by Dr. Jules Coleman of Denver, who has had a very wide experience with tuberculosis patients, the following occurred: a young man who had unilateral minimal tuberculosis received the news of his diagnosis as the equivalent of a jail sentence. He decided to have that last fling. Eight days transpired between the time of the communication of the diagnosis and his admission to the hospital. At the end of this interval, having had a high, wide, handsome time, day and night, he came in with advanced bilateral pulmonary tuberculosis. This is perfectly possible — one's physiological condition can deteriorate thus rapidly, permitting the spread of the tubercle bacilli.

Other persons, when the diagnosis is communicated to them, believe that if they carry out the prescribed treatment, such as going to a sanatorium, their friends will never again want to have anything to do with them. They feel, in short, they will be as rejected by everyone as though they had leprosy. Nobody will want to associate with them, everyone will be afraid of them. This is their obsession. Thus, the communication of the diagnosis to some people means "I've lost all my friends. I'll have to move away."

To other people, the main thought which occurs is "I'll be on my back, helpless, not earning anything for a year or more. I'll be completely dependent." To persons who have always been self-reliant, dependency is the cause of intense emotional distress. They find it difficult to accept the diagnosis chiefly because it involves complete dependency for a fairly long period.

To still other people, the diagnosis of tuberculosis may come at a time when they are in the mid-stream of developing their career. Such people may feel as if everything, life itself, will now be interrupted and that opportunity for advancement may never return. Sometimes, of course, this is true.

Thus, the news of the diagnosis of tuberculosis may have any one of a variety of serious meanings to a patient. The doctor himself may know nothing of these meanings unless he learns them from the patient. The usual custom in the past has been to attempt to get nothing from the patient. The patient's reactions thus remained unknown to the physician.

Some of the things which physicians do in communicating diagnosis are known to be very ineffective. What I say here about doctors applies also to nurses and other members of the medical team. Both doctors and nurses must work together on this job. Doctors are usually the first to communicate the diagnosis. Among the ineffective procedures that doctors use at the time they communicate the serious news are these:

They may minimize the seriousness of the news and talk in a very vague and casual way about it. "Oh, you have a spot on your lung, but you'll be all right." Giving the patient this kind of false reassurance is no kindness whatever. The patient really must be prepared for what is going to happen to his life during the next year or two years. Not telling him what this is, not only leaves him open to a greater disappointment when he finds out what he is really up against, but may make him distrustful, first of all, of his doctor and later on, of any doctor or nurse, in fact of any member on the medical team. Thus, we have poisoned a very important source of security for him at the hospital, as will be discussed later.

Another thing the doctors could do, when indicating diagnosis and discussing what has to be done, is not to be overly optimistic about the duration of treatment for this disease. Very commonly doctors say, when communicating the diagnosis, "you will have to be in a sanatorium or in bed for six months or so, and then you will be all right." Tuberculosis is too unpredictable for that. Six months is almost universally felt to be too short a time for treatment—certainly until we have much better antibiotics than we have now. These patients look forward to recovery at the end of the specified time and the more they feel the disease has messed up their lives, the more anxiously they count on recovery by the exact day the doctor mentioned in his casual statement. When that day passes and they realize they are still ill, they tend to neglect themselves and to violate hospital rules. If at home, they go out and pay no attention to rest, and so on, and tend to have a rapid progression of the disease.

Another thing doctors tend to do is to give the tuberculosis patient a very optimistic portrayal of a year in a hospital, away from home and family. They talk about freedom from responsibilities, about freedom from worry and bills, and they minimize the difficulties of sanatorium life.

It is important to mention that the physician is usually pleased by a patient who accepts news of his diagnosis very readily and with a smile. The doctor thinks: "This is a good fellow, this is a good patient, he takes it with a smile—he'll go right ahead." There are a number of instances on record, some of these also described by Dr. Coleman of Denver, of persons who really have appeared eager to accept the news of the diagnosis. They agree with the doctor while in his presence. They give him no hint of what they are thinking, but they may never see a doctor again, they may never enter a sanatorium. Perhaps they put this smile on to conceal how hurt they are. Their behavior remains unpredictable after they leave his office.

Now what are some of the more effective ways of managing this total situation?

The doctor usually doesn't know what the patient is thinking or feeling. He certainly doesn't usually know what the patient's circumstances are or what this interruption in his life at this particular moment may mean to him. There seems to be no way out of this situation. But there is a kind of help which works in many other unalterable life situations. When a person has a difficulty to surmount, it helps him to define that difficulty by expressing himself. The difficulty he experiences is an emotional disturbance, emotional distress or anxiety (it makes no difference what you call it). He is temporarily disorganized. The best way to help the patient handle a difficult situation when he is emotionally disturbed does not seem to be to minimize the situation for him or to preach to him about what he should do. He seems to be unable to do the thing that is the best for him to do unless something else happens first. That something is that he seems to have to discharge the emotion which is in him. Afterward, he can often face his problem and plan more realistic action.

The person who has been unable to solve a problem when intensely disturbed may be able to solve it when he has discharged the emotion he feels. The job the physician has to do (or, if the physician begins the job, the nurse has to complete it) could be put like this: When announcing the diagnosis, one should wait to see what the patient will do and whether he does nothing, or a lot, or smiles acceptance. It is then up to the physician, after a brief pause, to allow the patient to react spontaneously, in an effort to find out what this news has meant to him. The physician could begin by saying: "What do you think about this"—a simple question, or "what does the disease, tuberculosis, mean to you?" or "what will this do to your life?" or, "who will take care of your family or children (if it is a woman who has children) if you have to go to a hospital?" The doctor must ask these questions and other obviously related questions—he must ask them briefly—and when he asks the question he must give the patient plenty of time to reply either by words or by expressed emotion.

If the patient wishes to cry for five minutes, that's what he should be allowed to do. If the patient wishes to talk and then break down and cry, that's what he must do. The doctor must not interfere with his emotional reaction. The doctor will then not only get some of these emotional disturbances out of the patient by this kind of technique, but after some of these disturbances have been expressed the doctor will usually have learned many things the patient has to face in his treatment. Furthermore, the patient is then more ready to confide other significant attitudes and fears, since that is the usual result of sharing an emotional experience. The two individuals have become closer. A doctor can hardly do a thing like this in less than fifteen minutes of continuous time in privacy with a person. He can't be interrupted by phone calls every few minutes, or people walking into the office—either the nurse or other patients. It requires some understanding of the fact that people do not communicate matters of emotional intensity unless they have privacy. It takes a few minutes for one person to warm up enough to tell another person something as important as what this news does to his life. Physicians need to understand that they have to allow time for the patient to go through this process—maybe only 15 minutes—that they have to allow this time in a setting of privacy where the patient feels he has the complete attention and interest of the doctor.

The physician may decide that he wants to have another session the next day, so he may say, "I'd like to talk with you more about this tomorrow." He doesn't have to make any promises up to that point. He doesn't have to describe anything in detail about what is going to happen concerning the treatment of the disease; just, "I want to talk to you some more tomorrow" is all he has to say, and the patient will come back. Now if this procedure is followed, whether two or three times by the physician, or in the beginning by the physician and then by the nurse, it can be very helpful because the patient feels that more than one person understands him. If this has been done properly something very important has happened. The patient has shared a very important kind of emotion, a very special kind of experience, with at least one other person.

And what is accomplished by this sharing of an important emotion with another person? The two people become tied together. In this case the patient becomes tied to the physician. The patient develops more confidence in his physician because of the sharing of an important experience, just as buddies at war formed life-long friendships not because they had pleasant experiences together necessarily, though that, too, can be true, but because they had escaped death together and talked about it. Once this close relationship is formed, the patient trusts his physician. The patient then has a much greater internal ability to stand discouragement, the long period of inactivity in the sanatorium, and the isolation from home which will be necessary for him to get his best chance to get well. So a strong patient-doctor relationship is established which the patient remembers and benefits from.

The social worker is another person who can contribute to this process of helping the patient sustain his internal stability until he gets well. She can be very helpful if there are children to be provided for or matters of family finances to be attended to while the sick person is away. This kind of assistance should be managed in the same way as above described, not only with the patient but also with the involved members of the family. Persons involved in the emotional disturbance of a patient can be treated exactly as the patient, by not minimizing the true situation, by not giving false reassurance, by not saying "buck up" or "be a brave person," but by finding out what it all really means to them and by allowing their emotional reactions free expression. Then these people are ready to discuss what to do if anything can be done. What can be done after this emotional discharge has taken place? Much more than we usually give people credit for.

The next phase in the course of the patient's adjustment to treatment follows admission to a tuberculosis sanatorium. Several factors may influence him to leave the hospital. With the proper understanding on the part of the medical team, he may remain in the hospital. Important to remember about the hospital situation is the fact that the patient is isolated from all the people that he loves and from all his friends. On account of this isolation—the fact that he is cut off from persons on whom he has relied for affection, understanding, friendship and so on — several things may happen. The patient may become extraordinary sensitive to anyone who shows special interest in him in the hospital. If the doctor takes interest in a patient cut off from any other affectional support, the doctor immediately becomes extremely important to the patient. The nurse, similarly, becomes very important, the occupational therapist, the recreational worker, the librarian, any one of these can become equally important to the person whose affectional life has become practically nothing in the sanatorium while he had a normal social life and companionship outside. Thus a doctor who is very pleasant to the patient one day and pretty cold to him the next (because he himself has been up late the night before or is bothered about his own problems) has an overpowering effect on a patient who has become extraordinarily dependent upon that doctor's attitudes. The same applies to other members of the medical team, from nurses to attendants. If they have problems in their own personal lives, which they bring to their work, so that their behavior towards these patients, to whom they mean so much, goes up and down in an unpredictable way, the patient's emotional reaction also goes up and down in an unpredictable way, because he feels that he has been alternately indulged and deserted. Such unpredictable desertion may be the time when the pateint leaves the hospital.

The hospital personnel is extraordinarily important in sustaining the morale of the person isolated from friends. Often hospital personnel are completely unaware of this. They may not be doing a good professional job. They may not be especially interested in this patient. But, because he has nobody else, they are now the most important figures in the patient's world. What they do is of extreme importance, and they must learn to behave in a sustained friendly way toward such patients, as is necessary in a hospital situation. It doesn't do for them to behave as Betty MacDonald described in her book, "The Plague and I," to come in one day to find a patient disagreeable and say, "Well, if you don't like it here, you can go home any time; there are thousands who would be glad of the chance to have your bed." That will solve nothing, the patient may very well go home, and some other patient will take that bed, and behave similarly. Nothing is gained by that.

One thing that one can do in the hospital to make the patient's stay more productive for him is to realize that it is difficult for him to be separated from his usual personal supports. How does one learn of these difficulties? Beginning at the time of diagnosis, an attempt should be made to find out from the patient exactly how he feels about being away from his family for the first time—or for so long—from friends and from his work satisfactions. In other words, let the patient express how he feels about his isolation. Then discuss with him the pros and cons of "should I go back or should I stay here?" Let him discuss this freely and he will be helped to come to the conclusion: "if I want to live, I'd better stay here under treatment." But he may have to go through this entire process.

Another major point of importance during the hospital stay has to do with the enforced inactivity of bed rest. Most of us have no idea how hard it is to reduce our activities to the level the doctors characterize as absolute bed rest. Most of us have no conception whatever of what bed rest involves. Doctors and nurses themselves are extraordinarily poor patients in this respect. This is well known in any hospital where doctors have been patients.

What happens when a patient who is really able to be active is told to be completely inactive? He often becomes extremely restless and hyperkinetic. As they say in the army, he does "ten miles a day in his sack." What does the doctor gain by this? Nothing. If you will measure such a patient's cardiac activity, respiratory activity, and other kinds of nervous system activity, you will find that he is probably no less active than if you permitted him certain standardized kinds of co-ordinated muscular activity which he could easily do.

It is very common that when a patient's activity is reduced below a level he can stand easily, he becomes preoccupied with old thoughts, old fears, anxieties over things long past. He will recall evil things that he did in the past which have never bothered him before. Such thoughts may be of events of five, ten, or fifteen years ago. Suddenly now they come to the surface and he is constantly obsessed by them. Such a patient often becomes extremely anxious about dying, fearing that his disease is about to kill him. He may have exaggerated fears in relation to the demonstrable stage of his tuberculosis. Such exaggerated fears may occur in any kind of disease, just by making a man inactive. Inactive patients tend to become very hypochondriacal, noting every kind of sensation in their bodies and wondering if these symptoms indicate they are getting worse. They become increasingly skilled at observing their sensations, since by the doctor's orders, they have nothing else to do. They ask for remedies for these various sensations to such an extent that the doctors characterize them as demanding, whining, complaining. All this talk with doctors and nurses about symptoms, real or imagined, contradicts the purpose of bed rest, and they are being just about as active, it seems to me, as though they were permitted some activity. The patient soon becomes prejudiced against the doctor because of his attitude toward these reported symptoms. It is important that the doctors recognize that while these symptoms are not bona-fide in the sense that they can be treated with medicine, they are significant. Because the doctor is in a position not to accede to the demands of the patient, the patient gets mad at the doctor. He talks against the doctor—to him or to other people about him. He usually talks a lot and in a loud voice and again he isn't getting bed rest.

In tuberculosis hospitals, when the routine x-ray period comes around, say every month, some of the patients who take inactivity hard, tend to have a fever the night before x-rays, "x-ray fever." Or, they may develop sudden chest pain. Their temperatures actually may rise a little. There is known to be increased instability of the temperature regulating mechanism when people are upset.

Again, the attempts to maintain bed rest may be interfered with by bad news from home. A person who is doing as well as might be expected suddenly becomes hyperkinetic on receiving a letter about some family problem.

The sex drive is also a problem for patients who are kept inactive. The majority of tuberculosis patients, until recently, when the age range has been going up, have been in the younger age group. They have not worked out their sexual life in marriage. They are young and vigorous. They find themselves deprived of all muscular activity, social life, emotional life, and sexual life, and they tend to experience difficulties with sexual fantasy, masturbation and the like, again contradicting the purpose of bed rest.

Thus, it seems to me, that the whole problem of bed rest needs more reasonable handling. One can determine to what level a patient's inactivity can be reduced. Surprising discoveries can be made by asking simple questions. There are patients who will report that as far back as anybody has ever told them about, from the earliest days of childhood, they never sat still. You can't expect such a patient to lie down for a year and not move. There are patients who never had a nap at any age in their lives for more than a couple of minutes, and so on. It is, therefore, necessary to find out what the capacity for inactivity is for the individual patient.

It might be more effective to permit certain kinds of muscular activity, such as sitting up in bed for meals, getting out of bed into a chair regularly three times a day, or bathroom privileges once or twice a day. The patient could thus be permitted to discharge a considerable amount of muscular energy, which discharge might enable him to be inactive for most of the day. Occupational therapy in bed is also helpful. Combinations of such measures would actually achieve the kind of results doctors aim at, and believe they are getting, but which often are not really being obtained.

The patient needs special help and understanding when there is necessity for surgical treatment. He must be told that the relatively simple measures which it had been hoped would help him are inadequate and that something more drastic must be done. Again the physicians behave somewhat as they usually do when they communicate the diagnosis. They tend to promise magical relief as a result of treatment such as thoracoplasty and collapse therapy. They tend to pay no attention to the patient's concern about the results of some of these operations. They have no idea what the patient understands when they announce that he needs an operation. They don't bother to find out what the term "a collapsed lung" means to a patient. Some patients apparently believe that the doctor will literally crush their lung, that they will lose one lung completely.

In general, the surgeon should follow the same procedure previously outlined for the physician in communicating the diagnosis. When he announces the news, he should allow for a type of emotional blackout and allow time for the overt expression of whatever reaction is occurring. He can then discuss the possible alternatives to the operation. This is a type of psychological preparation for operation which every surgeon ought to know how to do in three or four minutes. Because the patient knows the surgeon is going to have his life in his hands, he is in a strategic position to do this job well—a position far superior to that of the person whom the surgeon regards as better qualified, the psychiatrist. The psychiatrist does not have this strategic relationship with the patient. The psychiatrist, atempting to do this job, after the person already has become very upset, needs as much as ten to twenty minutes more time if the interview is to be successful. Sometimes he is never successful. The patient may leave the hospital through his fear of the operation.

Now, when the time to discharge a patient comes, one of the problems to consider is that the patient may have adjusted too well to inactivity. He may have been impressed with the dangers of activity. He has become aware of the tiniest unusual sensation, when he moves around in bed, and feels guilty because he is violating bed rest rules. So, when we say, bed rest is over, you can get up and move around, he may experience a return of these sensations, and is constantly fearful of a relapse. It is not uncommon, here and there, to meet patients who have been discharged from the sanatorium with arrested tuberculosis and who, fifteen or twenty years later, are living as though they still had active tuberculosis. They are unable to make a move, without experiencing various disagreeable sensations, rapid heart, coughing, sweating and so on, which they mistakenly attribute to tuberculosis. These are properly to be attributed to poor physical condition due to prolonged inactivity. Such people remain invalids for the rest of their lives. We have conditioned them too well to inactivity. There is a special hazard at this time as they go from inactivity, which was necessary for their treatment, to resume normal life. When, under supervision, we increase their activity level up to the point where they can stand these unusual sensations without fear, people who have been invalids for some time can be rehabilitated. Physical therapists can do this alone if the patient understands his own reactions and wants to become stronger.

There is the question of what the patient shall do when he leaves the hospital—he may have to look about for a different kind of occupation. It is necessary to understand how important this may be to a patient. One of the problems is how to prepare a person for an entirely different occupation under physical limitations relatively new to him. Many of these patients need, in addition to help on becoming more active, special vocational training, vocational hardening for their old occupations, or vocational retraining and hardening until they reach their maximum work capacity. Then they are better prepared to leave the hospital. There are some patients who will always do less than the work they could do, fearful that if they do too much they will become ill again. There are patients who will overdo at this stage, in an effort to prove to everybody that they are going to be successful at the new job and as a well person. There are patients who are so upset as they face the problems of active, normal life, that they experience many symptoms such as fatigue, slight temperature rise, and sweating. Often it is obvious that these symptoms have nothing to do with tuberculosis. Sometimes it is not so obvious because the body has an extraordinary capacity to reactivate symptoms of a sickness under new stresses. So it is not always clear what these symptoms are and often such patients are suspected of actual relapse.

Many of these people are actually afraid to return to normal life after being in the hospital for a while. A University student realizes he is a year or two behind his previous classmates. It may be unpleasant to return. A man in business, realizing he has lost a year or two, may fear that he may not be able to compete with others who had no such setback. This may cause enough emotional disturbance so that he doesn't co-operate in the process of rehabilitation. Again, the patient's difficulties should not be minimized. They can't be just labeled "oh, that's just in your head." Although these reactions are psychological, they are none the less real and must be considered carefully in the process of aiding the patient to become a well and healthy person again. Again, the method is the same: help the patient to express his difficulty fully. Encourage him to reveal exactly how he feels about it. Then, and not until then, you can discuss effectively how to face the real issues and help give him courage to go ahead.

One vital point relating to discharge has to do with relapse after discharge. When a patient who has done pretty well under treatment returns to the sanatorium after discharge as a relapsed case, it is always worth while to find out what happened in his life during the interval between discharge and relapse. There may have been some special difficulty when the person tried to work out his life outside the hospital. That difficulty may have been too great for him to master and he has responded to that difficulty by a loss of appetite, insomnia, taking too much alcohol, staying away from home or quarrels with his family. Any one of a number of these things, when carried on, for a number of weeks or months may have the end result of depleting him physiologically and then the relapse may occur. So it is always well to investigate how a person who has a relapse has lived following his discharge with arrested tuberculosis.

There is one more variation of this general problem of treating the sanatorium patient which involves special consideration. I refer to the person who has never thought he had tuberculosis, who may have no symptoms at all but a test shows something suspicious. The diagnosis is uncertain but points to a possible tuberculous infiltrate. How long should a doctor keep on having experts do various kinds of tests before he says forget about it, or sends the patient to the sanatorium? What happens to the patient without a definite diagnosis of tuberculosis who goes to a sanatorium, stays there a year, and then is told he never had the disease? The impact of such news after undergoing treatment may be disastrous.

The problems which I have mentioned, which seem so important for sustaining the co-operation of the tuberculous patient with his medical advisors, have aroused only the occasional interest of medical personnel. By and large, there has not been anything like the interest in this aspect of chronic disease, including tuberculosis, which the subject and the number of relapses warrant. When proper attention is given to the emotional problems of the chronically ill, astounding results are observed. We already know from a few experiences that when this sort of attention is given to the patient as a person, discharges against medical advice fall markedly below their previous rate. In some VA hospitals where for two years, they have tried to treat patients in this way by increasing their social work staff, a 20 or 25 per cent decrease was shown in the percentage of patients who walk out of the hospital without receiving maximum benefit.

In a report to which I have previously referred —the November 5, 1948, U. S. Public Health Reports, Tuberculosis Control Issue No. 33, we have all the data to support us if we attempt to carry out a program along these lines.

How to carry out such a program in a sanatorium is the next thing to discuss. First of all, there won't be enough psychiatrists in our life time to do this job. They can't be trained that fast. Many psychiatrists aren't interested in work of this kind. But I am not certain that we need psychiatrists for most of this job. Actually, many other personnel of the medical team have more influential contact with the patient than have the doctors, so this is a problem for every member of the medical team responsible for the care of a person with chronic illness, such as tuberculosis. Every person on such a team, from the attendants at the hospital up, should understand some of these basic principles about how to help people who must face and are facing difficult situations. And if the team really does understand these problems of patients, and acts as a team, they can do much toward their solution. Perhaps the best use of a psychiatrist is as a member of this medical team and not in an individual relationship with the patient—that is a real possibility. How could we better use the help of one individual with the kind of psychiatric skill which I have been describing than by having him impart some of his "know how" to those handling patients daily?

How can we get these skills more widely distributed? Various methods have been discussed. One way which seems feasible—the VA way, is to put more social workers on the hospital staff. We can't do that in every hospital; there just aren't enough social workers. Another way which seems feasible would be to extend as far as possible the knowledge of the especially interested psychiatrists. They are the only ones the doctors would listen to, if they would listen to anybody. They won't listen to a social worker or let a social worker run a medical staff conference in a tuberculosis sanatorium, but they might permit a psychiatrist to attend conferences as a consultant.

If we could then have one competent psychiatrist in an area where this kind of program is desired, the best way to use whatever time he had available, I think, would be to have him come to regular conferences of the staff weekly. The doctors, social workers, occupational therapists, recreational workers and school rehabilitation and hospital counselors and attendants could then study a single patient in detail and much could be accomplished. The psychiatrist could rapidly raise the level of understanding between staff and patient. The result might well be a change in the whole atmosphere of the hospital. We have seen this happen a number of times with student nurses. We have seen whole wards where there had been conflict between patients and nurses (especially when the nurses were beginners) become quite harmonious places, with patients attending to their proper routines and getting well. We have seen the nurses much happier and understanding their patients much better. I am sure this could be done elsewhere just as well as in a general hospital.

The VA recommendation as to how to solve this kind of problem, based on their experience, is very simple: a large increase in the number of social workers and psychiatrists for all hospitals. It is very easy to suggest this, but they can't do it any more easily than we can. I think we will have to be more ingenious. We will have to find other ways of raising the general level of skills of the medical team in dealing with the patient. We may even learn to make more skillful use of group conferences of patients in various stages of the disease and hospitalization.

Finally, I would like to say there is nothing that I have said that is limited to tuberculosis. Any chronic illness, even a personality illness like a psychoneurosis or a psychosis that goes on for years, improves if handled by exactly this same method—sustained co-operation with the person with whom one has a special kind of relationship based upon sharing important experiences and upon a belief in his competence. This seems to be the chief weapon. More understanding and practice of this particular technique will solve many problems of the chronically ill.

The use of this technique will be just as necessary even in the years to come when tuberculosis sanatoria may no longer be needed. Some of the experts in the field of tuberculosis believe that if streptomycin is reasonably successful as an antibiotic in treating tuberculosis, improved antibiotics will be discovered and that within ten years or so it is not impossible that tuberculosis will be treated on an ambulant basis. The tubercle bacillus, however, is so tough chemically that it is unlikely that treatment can be shortened, so again we will have the problem of long cooperation with our ambulant patients. This could be simpler than the hospital situation, of course, but again long co-operation—the ups and downs of treatment—the different kinds of treatment that may be necessary if the antibiotic alone doesn't work. Again we have the fundamental importance of building up the kind of relationship between the patient and doctor which makes sustained co-operation of the patient easy and natural instead of handicappingly difficult.

Summary

For the chronically ill person to utilize the best knowledge and skill, he needs to be able to sustain co-operation with medical personnel, often under discouraging conditions. Principles found effective in psychotherapeutic medicine can be used to help him achieve this capacity for co-operation to a satisfactory degree.

TYPHOID FROM ABROAD

During the first five months of 1950, only five cases of typhoid and paratyphoid fevers were reported to the Minnesota Department of Health. The same number of cases had been reported at the same time last year. However, the total number of cases in the state in 1949 was twenty-one, with one death. Some of these cases were brought into Minnesota by visitors from foreign countries or by returning vacationers who had traveled abroad, says Dr. C. B. Nelson, director of the Division of Epidemiology, Minnesota Department of Health. In 1948, we had twenty-eight cases of typhoid and paratyphoid fevers, with four deaths. This was a rather high percentage of deaths, which usually occur in about one out of ten cases.

With the vacation season now in full swing, Dr. Nelson advises inoculations for all persons going to areas where typhoid fever is prevalent or sanitation is poor. Several cases previously reported here have been brought in from Mexico and Central America. France has also been a source. A caravan of college students and faculty people from Saint Paul went on a tour of Mexico in the summer of 1947, and three of them later came down with typhoid fever.

The health department also urges travelers going abroad to obtain vaccination against smallpox and immunization against any other diseases they may encounter for which preventive measures are available.—*Minnesota Health,* June, 1950.

HEMANGIOPERICYTOMA

An Unusual Extrarectal Tumor

HARRY E. BACON, M.D., F.A.C.S., LLOYD F. SHERMAN, M.D., and
WILLIAM N. CAMPBELL, MD.
Philadelphia, Pennsylvania

EXTRARECTAL tumors occur relatively infrequently. Yet, if one were to judge the incidence of these tumors by the number of cases reported and articles that are published in the literature relative to thier occurrence, a false impression would surely be gained. Of 2,100 operative procedures performed on the anus, rectum, and adjacent structure (excluding the colon proper), in the department of proctology at Temple University Hospital during the three-year period from January 1, 1947 to January 1, 1950, only three of these procedures were for the extirpation of primary extrarectal neoplasms.

Tumors which originate in or occur anterior to the sacrum constitute the most frequently reported extrarectal lesions. Here dermoids, teratomas, and chordomas lead other neoplastic lesions in incidence. The occurrence of ependymomas, neurofibromas, fibrosarcomas, giant cell tumors, and Ewings tumors have been reported.[1,3,5]

Neoplastic lesions may occur lateral to the rectum in the ischioanal fossae. These lesions are even more uncommon than those that occur in the retrorectal area. Chavelet[2] in 1908, was able to collect only eleven reports of neoplasms in this location. Sheddon[6] in 1934, reported three cases of sarcoma in the ischioanal region; however, from the descriptions given the specific types could not be ascertained. Jackman[4] in 1940, reported four neoplasms in this area from the Mayo Clinic files. They were a "lipomyxoma," a lipoma, fibroma, and a dermoid cyst.

Tumors may have their origins lateral to the rectum in the supralevator or pelvirectal spaces. However, this is probably the least common site of all extrarectal tumors. Fibromas, neurofibromas, neurilemomas, angiomas, and their malignant counterparts are the usual types of tumors found within this area.

It is the purpose of this paper to report the occurrence of a tumor having the cytologic features of a "hemangiopericytoma" in the pelvirectal space. Until this time no other tumor of this histologic description has been reported to have occurred in this location. According to Stout,[7,8,9,10] who, with Murray in 1942, first called attention to this lesion, approximately thirty-five "hemangiopericytomas" have been recorded to date in the literature. Tumors fitting the description of "hemangiopericytoma" may behave in either a benign or malignant fashion. Stout cited definite proof of malignancy with metastasis in six of the thirty-five lesions that he reviewed, while seven other tumors of the thirty-five showed aggressive growth without metastasis. Many of the other cases were followed inadequately after operation. In most instances it was not possible to distinguish between the benign and malignant tumors histologically.

It is only fair to state that much disagreement exists about the exact nature of these neoplasms. Whether they actually constitute a distinct entity remains to be ascertained. Diagnosis rests entirely on the histological finding of well formed capillaries surrounded by a varying number of ovoid or spindled tumor cells. Silver staining to accentuate the connective tissue sheaths of the capillaries is said to be of aid in diagnosis, but any highly vascular undifferentiated mesenchymal tumor might show similar feature.

Case Report

The patient (M.B.) is a white man, fifty-six years old, a barber by trade, who presented himself to his family physician in August 1949, because of a mild exacerbation of bronchial asthma. The patient requested a complete physical check up; so the family physician, being an astute practitioner, complied with the patient's request and incidentally discovered an extrarectal tumor mass. The patient was admitted to the proctologic service of Temple University Hospital on October 12, 1949.

Further questioning disclosed a history of normal bowel habits, with no history of bleeding or pain. He had had no previous rectal or extrarectal complaints, treatment, or surgical procedures. In fact there were no symptoms whatsoever referable to the tumor mass. His past history was not significant except for mild bronchial asthma for eleven years prior to this admission.

Physical examination revealed a well developed, mod-

erately obese white male, 5 feet 4 inchs tall, weighing 155 pounds. He was ambulatory and appeared to be in good health. The chest was clear to ausculation. Physical examination otherwise presented essentially normal findings, except for the rectum. Here, a digital examination revealed the presence of a firm, discrete, golfball sized mass lateral to the rectum in the left pelvirectal space. The lower margin of this mass was located eight centimeters from the anal verge. The mass was not mobile, and pressure did not cause any unusual sensation of pain. The mucous membrane over the lesion was freely movable. Proctoscopic examination revealed slight bulging of the rectal wall in the region of the palpated mass. No intrinsic pathology was noted in the rectum and sigmoid colon to 25 centimeters on sigmoidoscopic examination.

Laboratory Findings:—Hemoglobin—15.3 gms; red blood count—5,300,000 cmm.; white blood count—8,500 cmm.; differential—within normal limits; urinalysis—normal; blood urea nitrogen—11 mgm/100 ml; serum chlorides—343 mgm/100 ml; total serum protein—5.3 gms/100 ml; prothrombin concentration—100 per cent of normal.

X-Ray Findings.—Films of the lower abdomen and pelvis showed no abnormalities. Chest roentgenogram showed mild emphysema, but no other abnormality was noted. A double contrast barium enema revealed no evidence of any abnormality anywhere along the course of the colon. However, the rectum did not seem to possess its usual capaciousness. The rectal ampulla did not appear as wide and as ballooned out as is normally seen, but no discrete filling defects were observed.

Operative Procedure.—A suspension of sulfathaladine was administered orally for seven days and a solution of streptomycin for 48 hours preoperatively. On October 19, 1949, the left pelvirectal space was explored. Under spinal anesthetic of pontocaine (6 mgm.), dextrose (100 mgm.), and neosynephrine (2 mgm.), the patient was placed in jackknife position and the left ischiorectal fossa was entered via a 10 centimeter curvilinear incision midway between the anal canal and the left ischial tuberosity. The levator ani muscle was spread by a long hemostat and retracted to expose the left pelvirectal space. Here a firm, yet somewhat cystic mass, approximately the size of a golfball, was palpated. This mass was situated midway between the rectum and the left sacroiliac joint. It was well encapsulated, but rather firmly fixed in place by fibrous and areolar tissue. The lesion was extirpated by combined sharp and blunt dissection. The wound was then packed lightly with iodoform gauze and left open. The postoperative course was uneventful and the wound was completely healed in two months.

Pathologic findings.—

Gross Description—The specimen is a fairly well encapsulated tumor mass approximately 4 centimeters in diameter. It is moderately firm. Cut surfaces present occasional minute cystic areas, and a hemorrhagic appearance.

Microscopic Description—The tissue is extremely cellular and composed of numerous oval and spindled cells whose nuclei are relatively uniform in appearance. The cells have a paucity of pink staining cytoplasm. These tumor cells appear to surround numerous tiny capillary channels. In some areas dilated vascular channels predominate. Here and there are pigment-laden macrophages. Silver stain reveals the tumor cells to be outside of the sheaths of the capillaries. Trichrome staining was not significant.

Comment

The slides on our specimen were sent by our pathologist (Dr. Peale) to Dr. A. Purdy Stout of Columbia University who is Professor of Pathology. In his letter of May 15 he states, "the silver impregnation slide

(Continued from Page 693)

CLINICAL OBSERVATIONS OF EXPERIMENTS OF NATURE

C. A. McKINLAY, M.D.
Minneapolis, Minnesota

THE practicing physician, although denied the role of the scientist in following research, may, if sufficiently curious, participate vicariously in the experimental method. Every physician has the opportunity to observe those experiments of Nature that are set up by the influence of disease of one system or organ upon another. Sir William Osler[13] once said "As clinical observers we study the experiments which Nature makes upon our fellow creatures."

The interpretation of the physiopathologic train of events set in motion by such experiments of Nature challenges the ingenuity of the clinical observer. Because many of these sequences cannot be duplicated in the animal laboratory, the physician should be alert to the unique opportunity for study of factors which may not only give relief to the patient but which may give leads to the investigator in the laboratory sciences who is studying the nature of disease and searching for etiologic and therapeutic agents. Witness the years of careful clinical study by Hench[10] of rheumatoid arthritis and his emphasis on its remission during jaundice and pregnancy. This emphasis gave leads to Kendall,[10] the biochemist, in producing cortisone and other compounds which have broadened our concepts of disease and its treatment even before the mechanism of action of such compounds upon the collagen and other diseases has been clarified.

Furthermore, clinical analysis must precede the use of laboratory procedures if the laboratories are to be kept from creaking under their overload. Any analysis of cases reported is made from clinical data personally observed. The cases reported concern chiefly certain diseases of the thyroid gland, the blood and kidneys as related to the circulation, also to pulmonary infiltrations related to hypersensitivity.

Of particular interest to the internist and surgeon has been the relation of diseases of the thyroid to disturbances of the circulation. It may be stated that the opportunities for early clinical observation and treatment of thyrocardiac disease have tended to keep that disease a clinical rather than a pathological entity. The thyroid has lent itself to clinical study because of its accessibility to physical examination, to surgical extirpation and because apparently quantitative disturbances of its function produce not only well-defined clinical syndromes but also measurable metabolic variations. Parry,[8] in the first reported case of hyperthyroidism observed in 1786, some fifty years before Graves and Basedow, drew attention to the relation between the thyroid and heart; his patient had cardiac insufficiency and probably auricular fibrillation and angina pectoris.

Griswald and Keating[9] in a recent study of 810 cases of hyperthyroidism found that 12.5 per cent had thyrocardiac disease. Of those with thyrocardiac disease, 52 per cent had coexisting cardiovascular disease. Toxic nodular and hyperplastic glands had about equal dispersion in the group of thyrocardiacs. Personal experience indicates that nodular goiter of very moderate toxicity is more likely to be overlooked and to become a provocation of thyrocardiac disease. No characteristic pathologic change in the myocardium may be said to occur. Clawson[5] found only eleven thyroid deaths, one with myxedema, in the 9,934 cardiac cases which comprised 19.9 per cent of 50,730 autopsies from the Department of Pathology, University of Minnesota. Of interest is the finding of Dearing[6] and co-workers that extensive degenerative changes occurred in the myocardium of hyperthyroid animals which received toxic doses of digitalis.

Ablation of the normal thyroid to alleviate coronary insufficiency was reported in 1933 by Blumgart[3] and co-workers and performed by surgeons in this community. While having a rational physiologic basis of reducing cardiac work, the operation has fallen into desuetude to the best of the writer's knowledge, probably because it accomplished too little for too much surgery.

The place of the thyroid in the internal milieu influencing all tissues of the body is especially important as its behavior is related to the circulation and the nervous system. From the physiologic standpoint it is commonly believed that the extra burden due to acceleration of the circula-

President's address read in part before the Minnesota Pathological Society, at its meeting of April 18, 1950.

tion of blood and increased cardiac output for oxygen transport leads to cardiac insufficiency particularly in the presence of associated organic heart disease. A conflicting opinion has been expressed by Rasmussen[16] who, on the basis of careful animal experimentation, believes that the chief deleterious effect of increased thyroid hormone is not the creation of cardiac overwork, but is the causation of a variation in cardiac rhythm, that is, a functional heart disease, the essential features of which are paroxysms of tachycardia and auricular fibrillation, which leads to failure. This observer believes that the power of evoking paroxysms of sinus tachycardia is a peculiar and characteristic property of the thyroid hormone. Clinical experience also emphasizes the baneful influence of arrhythmia, particularly auricular fibrillation, upon the circulation. In cases of hyperthyroidism with decompensation, sustained auricular fibrillation was frequently present. The slow heart of an animal deficient in thyroid hormone or the rapid heart of the hyperthyroid individual has also been said to be due to a series of metabolic events some of which may be under hypothalamic regulation. Extrasystolic arrhythmia has also been associated with the stimulation of the posterior hypothalamus. To digress, in hibernation, which simulates an exaggerated state of myxedema, the marmot, studied by Benedict,[2] had a heart rate of 4 to 6 per minute; respiration varied from 1 in five minutes to 1 per minute. Arrhythmia of the heart during hibernation was noted which disappeared when the minimal normal rate of about 80 beats per minute was restored out of hibernation.

In cases of hyperthyroidism personally observed, particularly those in the fifth decade and beyond, auricular fibrillation or flutter has frequently supervened at some time, usually paroxysmally and when of short duration tended to disappear after thyroidectomy. Below forty years of age, decompensation has been infrequent. It is suggested that degenerative diseases are factors which indeed often determine the effects of the circulatory overwork factor of hyperthyroidism and also the pathologic anatomy of the heart. The frequency with which cardiac compensation has been maintained for years after thyroidectomy in thyrocardiac disease is noteworthy and speaks for early functional disturbance rather than for myocardial damage at that stage.

For illustration, Mrs. C., aged eighty, was in cardiac decompensation of brief duration with auricular fibrillation associated with hypertensive cardiac disease. Twenty-four years previously at the age of fifty-six, cardiac decompensation had occurred in association with exophthalmic goiter. Following thyroidectomy and recession of the hypermetabolism, cardiac compensation was restored and maintained through the years until the present episode of failure following an upper respiratory infection.

Following thyroidectomy in cases observed over a twenty-year period or longer, some of the individuals with the best health records have been those in whom the surgically induced hypometabolism has required replacement therapy with thyroid extract to maintain normal energy levels and basal metabolism. Miss I. M., aged sixty-one, observed for twenty-three years following thyroidectomy, has been well maintained on replacement therapy with grains ii to iii of thyroid extract daily and has had normal circulation. Incidentally, the removal of hyperfunctioning adenomatous goiter when an interloper in, or associated with, essential hypertension, has not materially influenced the course of the latter. Not referred to in this connection is the slight systolic hypertension and increased pulse pressure noted not infrequently in hyperthyroidism.

In contrast to the usual responsiveness to thyroidectomy is the experience of the nineteen-year-old girl with recurrent hyperthyroidism and severe exophthalmos, whose three operative scars attest to the inadequacy of that procedure. Radio-active iodine, given under careful direction elsewhere, was likewise ineffective. Reports of successful therapy with radio-active iodine in a considerable number of cases of diffuse hyperthyroidism suggest that such treatment may be the one of choice. The influence first of hyperthyroidism before thyroidectomy and later of post-operative hypothyroidism in precipitating decompensation has been observed and reported.[14]

Acute renal insufficiency related to disease of other systems was strikingly illustrated in the prechemotherapeutic era by the case of L. W., a young woman, who, working on research with a virulent staphylococcus culture known to be a high producer of exotoxin, became accidentally infected following a skin scratch and had rapidly developing lymphangitis, accelerated shock rection, extreme hypotension, and anoxia. Oliguria, anuria, and death occurred within hours. The hypoxia on the basis of overwhelming toxemia and resultant acute renal failure appeared to be the mechanism of death.

Mrs. J. N. appeared at the hospital with uremia and moderate azotemia and right pleural effusion. The blood showed increased serum proteins, reversal of albumin-globulin ratio, high sedimentation rate and rouleaux formation. The findings suggested consideration of multiple myeloma. This diagnosis was established by the finding of myeloma cells in the sternal biopsy material by the pathologist. Recovery ensued from the uremia and there was restoration of normal renal function although two years later death occurred with anemia and circulatory failure as prominent features. Uremia was the initial manifestation of disease. Bell[1] has stated in his text that renal insufficiency is frequently observed in advanced stages of multiple myeloma and that death may result from uremia. What factor was accountable for reversal of the uremia, which was the initial manifestation of the disease, remains unknown.

The following sequence of disease occurred in the case of J. H., a male aged thirty-six, married, who first appeared with erythema nodosum which occurred ten days after an attack of acute tonsillitis, and is deemed worthy of notation. About one year later diabetes mellitus developed and was recognized after a six weeks' period of weight loss. Appropriate insulin therapy was given. Approximately one year later myxedema with expressionless facies and skin changes developed (BMR minus 22 per cent) and responded to thyroid replacement therapy within three months. During the period of myxedema, clinical evidence of diabetes disappeared except for transient glycosuria during an upper respiratory infection. Seven months later acute infectious hepatitis developed and subsided. Diabetes mellitus reappeared, requiring 20 to 24 units of insulin daily for control. The trigger mechanism of acute pharyngitis appeared to precipitate erythema nodosum. Whether that mechanism was related to later sequences of diseases is speculative.

Apparently in this case imbalance between the activity of the pancreatic beta cells in the production of insulin on the one hand and of the anti-insulin or hyperglycemic factors of the thyroid, pituitary, adrenals, liver and diet on the other, mediated in part through the parasympathetic and sympathetic systems respectively, accounted for the development and temporary recession of the diabetes mellitus on the one hand and of the development and subsidence of myxedema on the other.

Physiologic adaptability of the body to anemia has presented a great variety of intersystem effects dependent, to a great degree, upon the extent and rate of development. H. L., aged forty-three, a housewife, consulted a throat specialist because of difficulty in swallowing. Other complaints of headaches, paresthesias in the extremities, and weakness appeared to be of secondary importance although first noted years previously. The throat examination was negative and further investigation was advised and revealed quite profound anemia (hemoglobin 6.3 grams, red cells 3,200,000), primary hypochromic anemia (hematologic study by Dr. H. Downey). Due to the insidious development of the anemia, the gradual physiologic adaptations were adequate enough until the primitive act of swallowing was interfered with. Recovery followed iron therapy. There was no spasm in the upper esophagus and the Plummer-Vinson syndrome was not suggested.

C. S., a male, aged sixty, a cook, neglected the treatment of pernicious anemia for ten months, entered the hospital complaining of cough, pain in the chest and weakness. The typical pallor had its counterpart in a hemoglobin of 4.5 grams, with 1,050,000 red cells per c.mm. When the anoxia conditioned by the low hemoglobin was successfully combated by the parenteral use of liver extract, the angina and cardiac decompensation tended to disappear while under hospitalization as the hemoglobin reached 11.2 grams. Electrocardiographic change supported the diagnosis of coronary insufficiency which became clinically manifest due to high grade anemia and anoxia of the myocardium.

Hypersensitivity of tissues has no more striking manifestation than that caused when the lung acts as a shock organ with huge infiltrations, presumably eosinophilic, with blood eosinophilia due to one of numerous chemical, infectious and/or foreign protein antigenic agents, the syndrome first described by Loeffler.[12] In a case reported by Dr. Ellis and myself[7] in 1941, the exciting agent was prontosil. In a second case, M. B., a farm housewife, aged thirty-six, similar infiltrations persisted for three years with blood and sputum eosinophilia. No provocative agent was found. A third case, recently under observation, is being reported elsewhere.

In the discussion of a group of cases in which multiple etiological factors may have elicited the same change, reference is made to the general adaptation syndrome emphasized by Selye,[17] with the stages of alarm reaction, the stage of resistance and the stage of exhaustion. If, as he states, conditions such as nephritis, rheumatic fever and acute peptic ulcer in some instance, occurred as the result of acute infection and in others could be traced to exposure to intense cold, an intoxication, or an emotional stimulus, the difficulty of interpreting the comparatively uniform response to diverse agents is no longer insuperable if it is assumed that certain lesions are produced by the response of the body to damage as such, rather than to one specific pathogenic agent. Hume[11] recently has presented evidence that the anterior hypothalamus constitutes an important link in the reaction of the body to stress. Included in the findings was the preparation of an effective extract of the hypothalamus which suggests a hormonal mechanism which, when activated in stress, is capable of causing increased secretion of ACTH.

Correlating the work of Cannon[4] on homeostasis, and the work of Selye[17] on the general resistance syndrome, Williams[18] suggests a phylogenetic concept which appears to make sense and which presents allergy not as an unprecedented kind of injurious mechanism which the animal organism has developed and preserved but rather as a gradual growth from the unicellular to the multicellular stage. Following the lead of Cannon[4] and as stated by Petersen[16] and Milliken,[15] the autonomic system, viewed as consisting of the semipermeable membranes of the individual cells, the hormonal system and the autonomic nervous system, is considered to be the physiologic mechanism by which the organism adjusts itself to all changes in its external and internal environment.

The case reports cited are an incomplete glimpse of the parade of the intersystem relationships which present themselves to the practicing physician. On the one hand, the clinician may be struck with the constancy, for instance, of the fundamental nature of the inflammatory reaction, whether called forth by viral or bacterial agent as in chickenpox and as in typhoid fever, respectively. On the other hand, host variation to this or that disease will always present multiple combinations of possibilities, conditioned by factors, beginning with heredity, that influence physiopathologic response.

With the thought that each case represents in some way a new experience and with the hope that as we continue to study medicine throughout our lives we may be more and more able to distinguish the significant from the unimportant, I wish to put in the mouth of the clinician, the words of Ulysses by Alfred Lord Tennyson,

"I am a part of all that I have met;
Yet all experience is an arch wherethro'
gleams that untravell'd world, whose
margin fades
For ever and for ever when I move."

TUBERCULOSIS IN SELECTEES DISQUALIFIED FOR THE ARMY
1942-1945

The Record in Minnesota

WALTER J. MARCLEY, M.D.
Minneapolis, Minnesota

THE Selective Training and Service Act, which established the Selective Service System throughout the country, was passed by Congress in September, 1940. On October 16 the first draftees in Minnesota were registered and were subject to examination by the physicians of the local boards.

Previous to January 1, 1942, the local board examiner gave the registrant a complete physical examination (a roentgenogram of the chest was not made), and upon the findings of the examiner the board was authorized to disqualify the registrant for military service, or if he was considered by the examiner to be qualified for service, he was sent to the Induction Station for induction. At the Induction Station he was given another physical examination by the Army, including a 4 x 10 inch stereoscopic photofluorographic roentgenogram of the chest and a 14 x 17 inch roentgenogram as indicated.

General J. E. Nelson, former state director, Minnesota Selective Service System, refers to this procedure in a personal communication as follows: "This double examination created many problems, due to the fact that registrants, having been examined by their local board examiners and found qualified, expected to be accepted by the Army, and many of them, upon examination at the Induction Station, were found not physically qualified and were, therefore, returned to their homes as rejected."

Beginning January 1, 1942, the examination of the local board examiner was limited to an inspection of the registrant, and upon the finding of any obvious physical defect, the board was authorized to disqualify him. If the registrant appeared to be without physical defect, he was sent to the Induction Station where he was given a complete examination.

However, the Federal Act authorized the local board to defer from service at any time certain registrants, as expressed in the Act, "whose employment in industry, agriculture, or other occupation or employment, or whose activity in other endeavors is found to be necessary to the maintenance of the national health, safety or interest."

Early in 1942 arrangements were completed for the reporting by the Army Induction Station of all Minnesota men examined and disqualified because of tuberculosis. The reports and also the chest roentgenograms made in the examinations were sent to the Division of Preventable Diseases, Minnesota Department of Health. These reports were received promptly day by day following the examinations. Among the first reports received were those of fourteen men examined in 1940 and 1941.

Dr. Leo G. Rigler, professor and chief of the Department of Radiology, University of Minnesota, was very much interested in the follow-up problem and volnteered to interpret the roentgenograms. The first reports were received March 8, 1942. From that day, and continuing through 1945, Dr. Rigler gave, without compensation, this most valuable professional service.

With the passage of the Selective Training and Service Act, the standards of physical examination as given in the War Department's Mobilization Regulations became effective.

The following specifications are taken from the Army Standards of Physical Examination dated August 31, 1940:

> "The chest examination will include the usual method of physical diagnosis supplemented when indicated by radiographic and laboratory studies."
>
> Listed as *"non-acceptable"*
>
> Lupus vulgaris.
>
> Tuberculosis either active or healed of any portion of the vertebral column, of cervical glands, of ribs or other parts of the chest wall, of a bone or joint.
>
> Fibrinous or serofibrinous tuberculous pleurisy and pleurisy with effusion of unknown origin.
>
> Tuberculosis of the lungs or tracheobronchial lymph nodes except as defined as follows:
>
> Arrested pulmonary tuberculosis consisting of lesions appearing in x-ray examination as small apical scars, small calcified nodules or localized fibrous strands, in no case exceeding minimal extent as defined in the classification of the National Tuberculosis Association, and when, in addition, in the opinion of the examining physician, this lesion is not likely to be reactivated under conditions of military service.

Dr. Marcley is Consultant in Tuberculosis, Minnesota Department of Health.

In later issues of the Army Standards of Physical Examination, reference is made only to tuberculosis of the lungs or tracheobronchial lymph nodes. In the issue of October 15, 1942, there are specified arbitrary limits in the size and number of calcified lesions that would be acceptable; and in the issue of April, 1944, there appears this general statement descriptive of an acceptable condition: "Calcified residuals of primary tuberculosis in the pulmonary parenchyma or hilum lymph nodes, provided the size, number and character of such lesions are not such as to suggest the possibility of reactivation."

The age limits acceptable for the armed services were changed from time to time. but the lower limit (twenty-one years in the original Act) remained constant until November 16, 1942, when it became eighteen years, and this continued through 1945. The upper age limit varied between twenty-five and thirty-seven years except that forty-five was the limit during nine months of 1942, and forty-four was the limit for almost one month of the same year.

In March, 1943, the Governor of Minnesota appointed the following named physicians as members of a "Tuberculosis Review Committee, Minnesota Selective Service System":

J. Richards Aurelius, radiologist, Saint Paul, clinical assistant professor of radiology; Malcolm B. Hanson, radiologist, Minneapolis, clinical assistant professor of radiology; Everett K. Geer, Saint Paul, clinical assistant professor of medicine; Thomas Lowry, Minneapolis, clinical associate professor of medicine; Leo G. Rigler, professor and head of the Department of Radiology—all of the University of Minnesota—and the writer, who is greatly indebted to the other members for their helpful suggestions in our follow-up activities and in the preparation of this report.

From March 8, 1942, to December 31, 1945, the Army Induction Station reported 1,758 registrants examined for the Armed Services and disqualified temporarily or permanently because of tuberculosis (including ten "suspected tuberculosis"). This number is made up of the following groups: 520 previously reported to the Minnesota Department of Health as cases of tuberculosis, 983 "new cases" permanently disqualified (sixty-three were non-residents), and 255 disqualified temporarily (deferred) and to be re-examined in six months.

Of the deferred group, seventy-five were later re-examined and accepted for service and fifty were re-examined and permanently disqualified. The remaining 130 (over 80 per cent were examined in 1944 and 1945) were not re-examined because of age or occupation.

The number permanently disqualified—520 known cases, 983 "new cases," and fifty permanently disqualified by re-examination, total 1,553—was 0.52 per cent of the total number of registrants examined during this period, estimated as 300,000.

Purvine and Erickson[6] reported in February, 1946, that of 117,598 men examined for service in Oregon, 0.8 per cent were disqualified as "possible pulmonary cases." Plunkett[5] has reported that of the men examined from November 25, 1940, to March 14, 1941, in Albany, Syracuse and Buffalo, New York, 0.9 per cent were disqualified because of "roentgen evidence of tuberculosis." Verstanding[7] has reported the findings in 100,000 photoroentgenograms in Connecticut as reinfection or primary tuberculosis in 0.67 per cent. Hyde and Sacks[2] have stated "of selectees examined at Boston Armed Forces Induction Station from December, 1940, to early in 1943, 0.9 per cent were found by x-ray examination to have pulmonary tuberculosis." Wile[8] reports that in 1941, of the men examined in the United States, 0.57 per cent were rejected because of tuberculosis; and Karpenos[3] has given the rejection rate for the entire country for 1945 as 0.71 per cent. Adamson[1] in 1945 wrote, "One and one-half million prospective members of the forces have been x-rayed and examined for tuberculosis in Canada," and that 1 per cent were found to have pulmonary tuberculosis.

Long[4] reviews in full the experience with reference to tuberculosis in World War II, and, in discussing the problems met by the examiners at the Army Induction Stations, he concludes: "But it is a fair estimate that 90 per cent of the significant lesions that should have been seen were discovered." Further on he states: "The cases of tuberculosis that escaped detection at Induction Stations were found in high proportion within a relatively short time by the medical personnel of army posts."

This study is concerned only with the "new cases," 920 Minnesota residents disqualified by the

TABLE I. COMPARISON OF DIAGNOSIS AT INDUCTION STATION, INTERPRETATION OF ROENTGENOGRAM, AND THE SUBSEQUENT DIAGNOSIS BY PRIVATE PHYSICIANS OR PUBLIC HEALTH OR SANATORIUM CLINICS

Diagnosis at Induction Station—Pulmonary Tuberculosis, Reinfection Phase 864.

Interpretation of Roentgenograms received	Section I					Section II
	Subsequent Diagnosis by Physicians*					No record of subsequent Diagnosis

TABLE II. COMPARISON OF DIAGNOSIS AT INDUCTION STATION, INTERPRETATION OF ROENTGENOGRAM, AND THE SUBSEQUENT DIAGNOSIS BY PRIVATE PHYSICIANS OR PUBLIC HEALTH OR SANATORIUM CLINICS

Diagnosis at Induction Station—Pulmonary Tuberculosis, Primary Phase 91

Interpretation of Roentgenograms received	Section I					Section II
	Subsequent Diagnosis by Physicians*					No record of subsequent diagnosis
	Reinfection phase	Primary phase	Other lung pathology	Negative	Total	
Reinfection phase (8)	2			3	5	3
Primary phase (69)	1	34	1	3	39	30
Other lung pathology (7)		1	1	1	3	4
Negative (3)				2	2	1
Total (87)	3	35	2	9	49	38
Roentgenograms not received (4)		3			3	1
Grand Total (91)	3	38	2	9	52	39

*Private physicians or Public Health or Sanatorium Clinics.

first examination and fifty by re-examination—total 970.

The diagnosis at the Induction Station was:

Pulmonary tuberculosis, reinfection phase	864
Pulmonary tuberculosis, primary phase	91
Extrapulmonary tuberculosis	5
Suspected tuberculosis	10
	970

The age groups were as follows:

18-19 years	52
20-24 years	135
25-29 years	212
30-34 years	242
35-39 years	211
40-44 years	83
45- years	19
No age given	16
Total	970

In Tables I and II, the diagnosis at the Induction Station, made after physical as well as x-ray examination, is compared with the diagnosis based on the interpretation of the roentgenograms of the chest only, and with the subsequent diagnosis.

As shown in Table I, of the 864 cases of the reinfection phase reported by the Induction Station, there are no records of subsequent examinations of 136; and of the remaining number (728), roentgenograms of sixty-three were not received for interpretation. It is of interest to note to what extent the diagnosis made by interpretation of roentgenograms only, and by subsequent examinations are in agreement with the diagnosis made at the Induction Station. This comparison can be made in only 665 of the reinfection cases as follows:

Interpretation of Roentgenograms

Reinfection phase in	81%	99%
Primary phase in	6%	
Other lung pathology in	12%	
Negative in	1%	

Subsequent Diagnosis

Reinfection phase in	80%	91%
Primary phase in	6%	
Other lung pathology in	5%	
Negative in	9%	

Of the primary cases (ninety-one) reported by the Induction Station, as may be seen in Table II there are no records of subsequent examinations in thirty-nine; and of the remaining number (fifty-two), roentgenograms of three were not received for interpretation. Comparison of diagnosis can be made in only forty-nine cases as follows:

Interpretation of Roentgenograms

Reinfection phase in	10%	96%
Primary phase in	80%	
Other lung pathology in	6%	
Negative in	4%	

Subsequent Diagnosis

Reinfection phase in	6%	82%
Primary phase in	72%	
Other lung pathology in	4%	
Negative in	18%	

Our follow-up activities have been carried on by correspondence, or other means of communication with physicians; school, city, and county public health nurses; sanatorium or public health clinics; and with many of the 970 Minnesota residents who were disqualified for military service.

Many have been checked up in the mass x-ray surveys which are being conducted throughout the state. Many have been interviewed by an epidemiologist of the Minnesota Department of Health. Of those who have left the state and whose new addresses have been known, reciprocal notifications have been sent to the Health Departments of the other states.

Follow-up Record to June 30, 1949

Subsequent Diagnosis.—Reinfection phase: 592 (589 in Table I and 3 in Table II).

276 admitted to sanatoria. Stage of disease on admission: minimal 61, moderately advanced 131, far advanced 77, pleurisy with effusion 3, admitted for observation 4.

30 died in sanatoria.

33 are in sanatoria June 30, 1949.

213 discharged, average period of treatment 13 months.

Status on discharge: 35 arrested, 60 apparently arrested, 48 quiescent, 37 improved, 24 unimproved, 2 others (1 admitted minimal discharged not tuberculosis, Loeffler's syndrome; 1 admitted far advanced discharged not tuberculosis, probably sarcoidosis); 3 tuberculous pleurisy with effusion (2 discharged apparently arrested and 1 improved); 4 admitted for observation (final diagnosis reinfection phase stable 2, diagnosis not established 2). 122 are stable and working, 13 stable and working in 1947 or 1948, 5 stable not working, 8 continue treatment at home, 2 have been accepted by the Army, 11 have died (6 of tuberculosis), 30 have left the state (16 report well and working), of 22 we have no record since discharge from sanatoria.

316 of the 592 reinfection cases were apparently not thought to be in need of sanatorium treatment. 194 are well and working, 45 well and working in 1947 or 1948, 1 has been accepted by the Army, 9 have died (4 of tuberculosis), 44 have left the state (16 report well and working), of 23 we have no further record.

Subsequent Diagnosis.—Primary phase: 83 (45 in Table I and 38 in Table II).

66 are stable and working, 1 has died of coronary occlusion, 3 have left the state (1 is in a sanatorium), of 13 we have no further record.

Subsequent Diagnosis.—Other lung pathology: 23 (31 in Table I and 2 in Table II).

12 definite diagnosis made: 2 atypical pneumonia, 1 bronchiectasis, 3 bronchitis, 1 cystic disease, 2 histoplasmosis, 1 Loeffler's syndrome, 2 silicosis. 1 left the state, died, and cause of death unknown.

20 diagnosis not established, no further record.

Subsequent Diagnosis.—Negative: 72 (63 in Table I and 9 in Table II).

Only 9 were negative by interpretation of roentgenograms and of 2 others roentgenograms were not received for interpretation.

51 are well and working, 7 well and working in 1947 or 1948, 1 has died (nephritis), 3 have left the state (1 reports well and working), of 10 we have no further record.

No Record of Subsequent Diagnosis: 175 (136 in Table I and 39 in Table II).

Of this number (175), roentgenograms were not received for interpretation in 5 cases.

Interpretation of Roentgenograms Only.—170.

Reinfection phase: 92 (89 in Table I and 3 in Table II). 37 stable and working, 15 stable and working in 1947 or 1948, 4 have died (not of tuberculosis), 1 has been accepted by the Army, 19 have left the state (2 have died of tuberculosis and 4 report well and working), of 16 we have no further record.

Primary phase: 47 (17 in Table I and 30 in Table II). 27 stable and working, 1 has died (not tuberculosis), 1 has been accepted for the Army, 6 have left the state (1 reports well and working), of 12 we have no further record.

Other lung pathology: 25 (21 in Table I and 4 in

Table II). 14 well and working, 5 have left the state, of 6 we have no further record.

Negative: 6 (5 in Table I and 1 in Table II). All are well and working.

Roentgenograms not received for interpretation: 5 (4 in Table I and 1 in Table II). 4 well and working, of 1 we have no further record.

Extrapulmonary Tuberculosis: 5.

Of the 5 cases, 3 were of the spine, 1 of the leg and 1 of the ankle. We have no record of subsequent diagnosis. The disease in all of them is apparently stable. Three report well and working.

Suspected Tuberculosis.—10.

3 admitted to sanatoria for observation: 2 diagnosis reinfection phase far advanced (1 died at the sanatorium, 1 in the sanatorium 1 year left the state following discharge, no further record); 1 diagnosis moderately advanced, in sanatorium 14 months now well and working.

3 subsequent diagnosis: 1 cystic disease, 1 bronchiectasis, 1 healed tuberculous pleurisy. All well and working.

1 subsequent diagnosis negative, no further record.

3 diagnosis not established, no further record.

Summary, June 30, 1949

In 659 the disease is stable or apparently stable.
- 528 stable and working.
- 80 stable and working in 1947 or 1948, no recent record (many of these two groups have continued in their former occupations).
- 8 stable, not working.
- 5 have been accepted by the Army.
- 38 have left the state and report well and working.

70 have left the state, no record regarding work.

43 have died of tuberculosis (31 in sanatoria).

18 have died of other causes.

34 are in sanatoria.

8 continue treatment at home.

22 no record since discharge from sanatoria.

81 have had follow-up examinations, no further record.

35 have not had follow-up examinations, no further record.

Total 970 selectees disqualified for the Army because of tuberculosis or suspected tuberculosis, 1942-1945.

Acknowledgments

The writer wishes to record his appreciation of the courtesies and ready assistance of General J. E. Nelson, former director, and Col. L. E. Lilygren, present director of the Minnesota Selective Service System, and their associates, Col. R. A. Rossberg, Col. Richard B. Hullsiek, and Col. Robert B. Radl. (The latter two officers were successively chief of the Medical Division, Minnesota State Headquarters.) He is also deeply grateful for the interest and the advice of Alan E. Treloar, professor of biostatistics, University of Minnesota, in the presentation of the statistical material.

HEMANGIOPERICYTOMA

(Continued from Page 684)

shows nicely the reticulum sheaths of the many blood vessels so that I feel satisfied that the pattern is correct for a hemangiopericytoma. Of the two Laidlaw impregnations and the one Masson trichrome stain, it will be noted that the last shows the absence of myofibrils in the tumor cells, thus excluding the possibility that the tumor cells are ordinary smooth muscle cells. The stain is adequate for smooth muscle by observing the reddened myofibrils in the walls of the few veins present in the tumor."

Comment.—The tumor has the appearance of a highly vascular, mesenchymal neoplasm. The problem presented is whether the vessels are an integral part of the tumor, or whether they represent merely the blood supply of the neoplasm. Because of the cytologic appearance of the tumor, and its striking vascularity, it would seem that the neoplasm most probably is of an angiomatoid nature. As such it may belong in the group of so-called "hemangiopericytomas." The course may be benign since the tumor appears to have been completely removed, both grossly and histopathologically.

Diagnosis—Vascular mesenchymal tumor, probably "hemangiopericytoma."

Summary.—An unusual extrarectal tumor is reported.

AN UNUSUAL TYPE OF PULMONARY DISEASE INVOLVING SIX MEMBERS OF A FAMILY

L. H. RUTLEDGE, M.D., F.A.C.S.
Detroit Lakes, Minnesota

THIS UNUSUAL pulmonary disease involved an entire family of six people of Scandinavian ancestry. The father, J. P. L., aged seventy-six, was a rather debilitated old man; Mrs. J. P. L., aged sixty-seven, the mother, was a healthy, well-nourished, well-preserved woman; T. L., the older daughter, aged forty-one, was a well-nourished, middle-aged spinster; R. L. aged thirty-one, the older son, was a husky, well-built, physically rugged specimen; D. L., aged twenty-four, the younger son, was only slightly less robust than his older brother; and lastly M. L., aged twenty-seven, the younger daughter, was a fine specimen of young womanhood. All lived in a good, clean, roomy farm home in rural Becker County, near Detroit Lakes, Minnesota.

The father, J. P. L., was critically ill for a long period of time. R. L., the older son, was acutely ill for nearly two months, made a good recovery, but still showed residual of the disease in the radiograph of his lungs twenty-five months after its inception. T. L., the older daughter, had a prolonged illness requiring nearly complete bed rest for over a year and developed some very unpleasant nervous symptoms during convalescence. Mrs. J. P. L. was not very ill and made a good recovery in a shorter length of time. D. L., the younger son, was ill a short time, was not hospitalized, and would not have been seen had he not come in over a year later with a cold. M. L., the younger daughter, was not examined until March, 1950. Cases are offered here in the order that they were seen.

Case Histories

Case 1.—R. L., male, aged thirty-one, became suddenly and acutely ill at noon, January 26, 1948, with severe chills, a sharp rise of temperature and a dry, unproductive cough. He had general malaise but no acute or localizing pain. The family reported a temperature of over 103° F. the night before admission, and the patient himself stated that he had a "bad case of flu." There was no nausea, vomiting or other gastrointestinal symptoms. There were no upper respiratory symptoms and no associated urinary complaints.

His past history was noncontributory and he had enjoyed very good health until the day before his admission, having never been hospitalized until January 27, 1948.

Physical examination showed a young, white man, well nourished, well developed, height 5 feet 10 inches, weight 180 pounds, lying quietly in bed perspiring profusely but in no immediate distress. He was alert and there was no delirium. The temperature was 103.6° F., pulse 84, respirations 20, blood pressure was 125 systolic and 65 diastolic. There was no acute tonsillar infection and there was no exudate in the throat or nasopharynx. The breath sounds were a little more distant at the base of the right lung. There were no râles; fremitus and percussion were normal. The heart showed no evidence of disease.

Course.—The patient ran an irregular temperature for eight days, varying from 100° to 104° F., then the fever gradually subsided, reaching normal on the thirteenth hospital day. He went home, against advice, on the fifteenth hospital day because he felt so well. He was home five days, and on the twentieth day of his illness he was readmitted to the hospital with a temperature of 101° F., and pain in the right lower chest, aggravated by deep breathing or coughing. Physical findings were much the same as on the former admission except that respirations were grunting, painful and shallow; the rate was 32 as compared with 20 per minute on previous admission. The percussion note over the right lower chest was less resonant, and tactile and vocal fremitus were decreased over the same area. The acute symptoms subsided in five days and a small amount of fluid was obtained at this time by thoracentesis. The fluid was serosanguinous and no bacteria were found by direct smear. From this point on, he ran a favorable course with a low grade temperature up to 100° F. until the thirty-fifth day of his illness and after that his temperature never rose above 99° F. On the twenty-eighth day of illness he developed a thrombophlebitis of the left femoral vein. Recovery from this was good and did not affect his hospital stay. He was discharged from the hospital on the fifty-fourth day after the initial onset and, except for a dry cough and being a little weak, was asymptomatic. The dry cough is still present in the morning after twenty-five months.

The routine laboratory tests were followed closely during the first two months with the hope of finding some trend or clue that would throw light on the actual diagnosis or yield something that was characteristic in this series of cases. The urine examinations were the same as would be found in any febrile, respiratory infection. Routine blood examinations with differential counts showed normal hemoglobin and red count findings in all cases, the white blood count was normal or slightly elevated and the differential was variable with no definite pattern. Repeated agglutination tests failed to show evidence of typhoid, paratyphoid, brucellosis and tularemia. Complement fixation tests were nega-

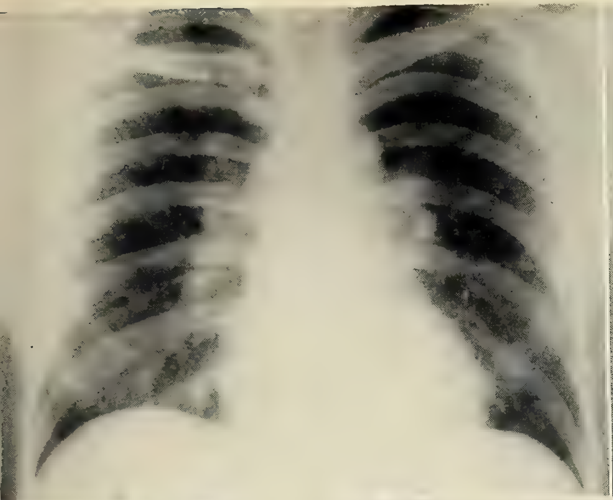

Fig. 1. (*Upper left*) Case 1. Radiograph of lungs taken on second day of illness. There is some infiltration of both lungs. Shadows about hili.

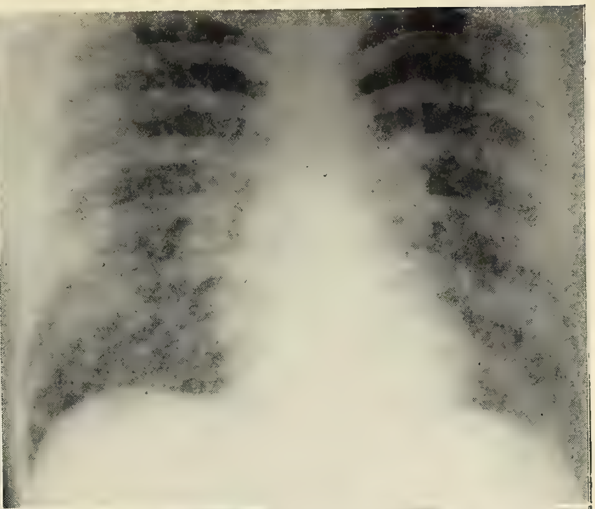

Fig. 2. (*Upper right*) Case 1. Radiograph taken on thirteenth day of illness. There is extensive involvement of all lobes in both lungs, definite nodular infiltration with coalescence of nodules, much like Case 2 and more rapid than Case 4.

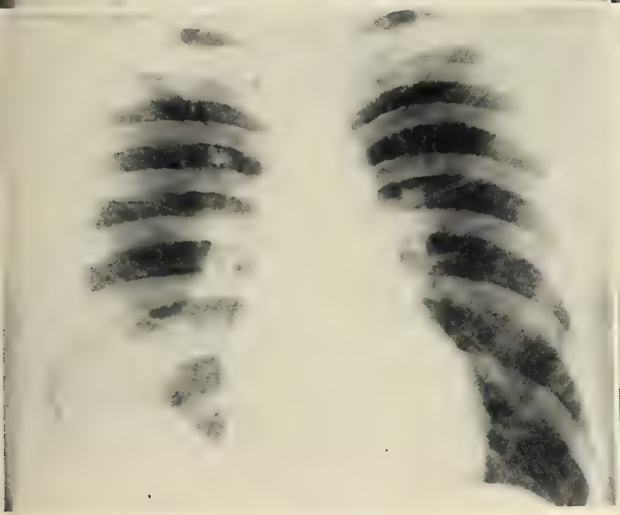

Fig. 3. (*Lower left*) Case 1. At the end of two months (March 31, 1948) radiograph shows definite clearing of both lungs. Pleurisy at right base evident.

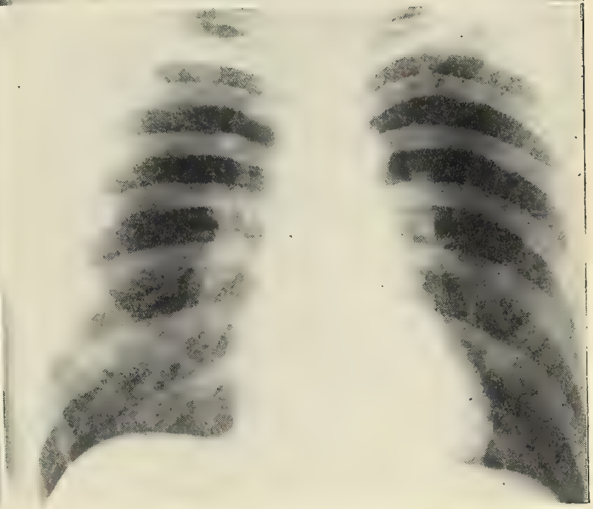

Fig. 4. (*Lower right*) Case 1. Radiograph taken March 13, 1950, or twenty-five and a half months after inception of disease. There is almost complete recovery but a few nodular areas are visible with fibrosis, particularly at right base.

tive for "Q" fever and ornithosis. The Kline exclusion test for syphilis was negative. Sputum was not obtained until the twenty-third day of illness when it showed many red blood cells, leucocytes and Gram-positive cocci occurring in pairs and chains. No acid-fast bacilli and fungi were found. Special cultures showed yeast-like organisms which were morphologically and culturally identical to Candida (monilia) ablicans. Guinea pig inoculations from the sputum were negative for acid-fast bacilli.

The radiographs (Figs. 1 to 4) taken of this patient's lungs at the onset and followed for twenty-five months, as in Case 4, tell an interesting story of minimal pulmonary infiltration initially, gradual development, pleurisy, massive involvement of both lungs with gradual clearing and partial resolution. The first film of the lungs on admission, the second day of the disease, showed an increase in the bronchovascular markings throughout both lungs with a few tiny nodules on the right side and a few on the left side in the middle portion. A week later there were numerous nodular densities extending from the apex to the base on both sides. Later, at the second admission, there was marked coalescence of the process with fluid in the right pleural cavity and diffuse nodular and infiltrative processes in both lungs from apex to base. Two months after onset, on March 31, 1948, radiographs showed the first clearing of the pulmonary condition. From then on, improvement was gradual but steady, and after twenty-five months the last radiographs of the lungs showed practically complete resolution of the old inflammatory process in the lung fields. Fibrosis was present in the right lower lung field, but nodularity had cleared.

Case 2.—Mr. J. P. L., aged seventy-six, was admitted to the hospital January 30, 1948. He was taken ill one day earlier, just three days after the onset of R. L.'s illness (older son). He had a rise of temperature, a dry cough, was weak and confused. His past history was of no consequence, except that he had had pneumonia following influenza in 1918; otherwise, he has always been well.

Examination showed his temperature to be 103.6° F., pulse rate 100, respiratory rate 40. The respirations were shallow with râles at the end of inspiration heard at the posterior bases of both lungs with more involvement on the right side. Vocal fremitus was decreased at the right base. His blood pressure was 150 systolic and 90 diastolic with marked arrythmia; peripheral sclerosis was considerable. The urine was involuntary with a residual urine of 30 c.c. The skin showed a red, indurated area on the bridge of the nose which spread out on the cheeks in a circle 2 inches in diameter and gave the impression of being erysipelas and not connected with the respiratory condition. He had a marked hypertrophic arthritis with general distribution. He was conscious most of the time but acutely ill with the outcome in doubt for several weeks. He was in no pain but presented the appearance of an exhausted, worn out, old man.

The course of disease was prolonged. This was partially due to heart disease, advanced arteriosclerosis and poor general condition. The first two days in the hospital, his temperature was 103.6° F., all readings being rectal in this case. From then on the readings were 101° to 102° F. with one chill. The temperature receded on the twenty-first day and reached normal on the twenty-seventh hospital day. At this period he did very well for ten days, but on the thirty-seventh day of hospitalization, he had a chill, with a sharp rise of temperature to 103° F. The elevation of temperature persisted with a daily low of 100° F. and daily high of 102° F. On his fiftieth hospital day it began to recede slowly and on the seventieth hospital day he became afebrile. His improvement was slow but constant and he went home on the ninety-eighth day of illness in fair condition. His general health is now good at the end of twenty-five months.

The laboratory findings in this case were noncontributory to the diagnosis. Urine examinations were well within normal limits. The blood examinations showed a negative Kline exclusion test. Red blood count was 4,600,000; hemoglobin, 14.4 gm.; white blood count, clear; polymorphonuclear, 65; lymphocytes, 32; mononuclear 3. Serum protein, 6.4 gm.; albumen, 2.4 gm.; globulin, 4.0 gm. Serological tests were negative for "Q" fever and ornithosis. Agglutination tests were negative for typhoid, paratyphoid, brucellosis, and tularemia. The sputum yielded nothing significant on direct smears or guinea pig inoculation.

The radiographs (Figs. 5 and 6), taken at frequent intervals, showed a well developed, diffuse infiltrative process with definite nodules as seen in Case 1 (Figs. 1 to 4) and Case 4 (Figs. 7, 8 and 9). This involved all lobes of both lungs, reaching a peak at about the end of six weeks, and began clearing slightly at the beginning of the ninth week, with marked clearing at the end of three months.

Case 3.—Mrs. J. P. L., aged sixty-seven, became ill January 29, and was admitted to the hospital on February 10, 1948. The onset of her illness was gradual with a nonproductive cough, chills and rise of temperature. The chills were not severe and usually occurred in the afternoon on succeeding days. She was gradually weakened by the disease and was hospitalized on the thirteenth day of her illness. Physical examination showed a white female, well developed, well nourished with no evidence of being severely ill or prematurely old. The temperature at admission was 98.6° F., heart rate 80, respiratory rate 20 with good mobility of the lungs and diaphragm. There was a moderate nonproductive cough with râles heard at the left posterior base during the entire inspiratory phase. There were scattered râles at the right base. The blood pressure was 140 systolic and 80 diastolic. The heart findings were normal. There was a moderate degree of hypertrophic arthritis.

She remained in the hospital sixteen days and did very well, running a much milder course than Cases 1 and 2. Her improvement continued at home and when last seen, in December, 1949, felt quite well and general physical examination was normal.

The same laboratory procedure was followed as in previous cases with essentially the same results. In this patient no sputum could be obtained.

Radiographs were obtained on admission, at the end of the first month's illness, near the end of the first year, and a last film on March 4, 1949. The findings were similar to cases previously recorded, but less extensive although all lobes of both lungs were involved. The last film taken March, 1949, showed considerable clearing as compared to films taken in 1948. The shadows at the lung roots were less dense.

Case 4.—T. L., aged forty-one, an unmarried, older daughter, was taken ill the last week of January, 1948, three days after R. L. (Case 1). The onset was not so acute as his. She went to bed with chills, fever, night sweats, malaise and general weakness. She improved after two weeks and was doing well until the first of March, 1948, when she reported to the office with a severe dry, nonproductive cough and pain in the right side of the chest. Radiographs of the lungs (Figs. 7, 8 and 9) at that time indicated findings similar to her brother, R. L., with nodular infiltration into both lungs. This, however, was not extensive at this first examination. Her temperature was 98.2° F. in the afternoon and the pulmonary findings were well within normal limits. During the following month (April, 1948) the cough grew worse, developed into severe paroxysms but was nonproductive and all attempts to collect sputum failed. The treatment was rest in bed at home until May 13, when she entered the hospital as she was having slight rises of temperature up to 100°F. with chills and night sweats.

Physical examination at admission showed temperature 100° F., pulse 90, respirations 22, blood pressure 112 systolic and 70 diastolic. She was well developed and well nourished, coughing and apprehensive but in no great distress. No râles were heard. All other phys-

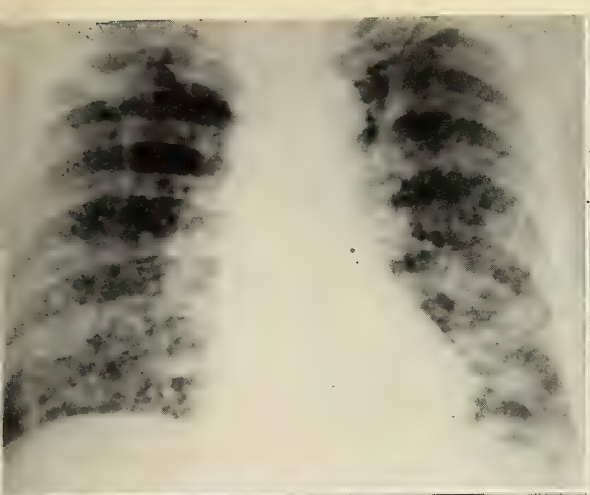

Fig. 5. (*Upper left*) Case 2. Radiograph taken four and a half weeks after manifestation of symptoms shows extensive nodular infiltration in all lobes of both lungs.

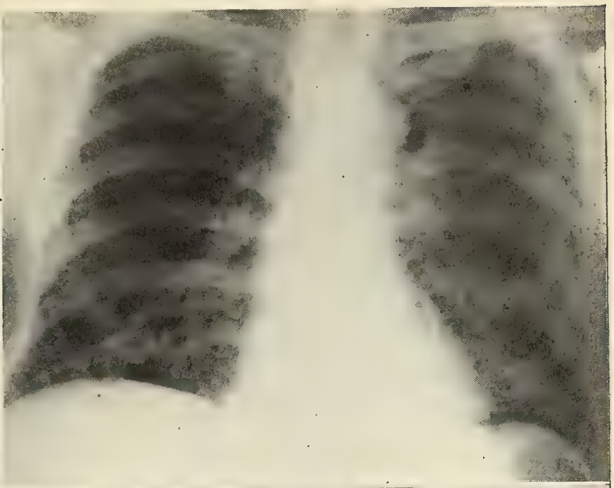

Fig. 6. (*Upper right*) Case 2. Radiograph taken April 30, 1948, shows good resolution after three months. Patient left hospital a week later.

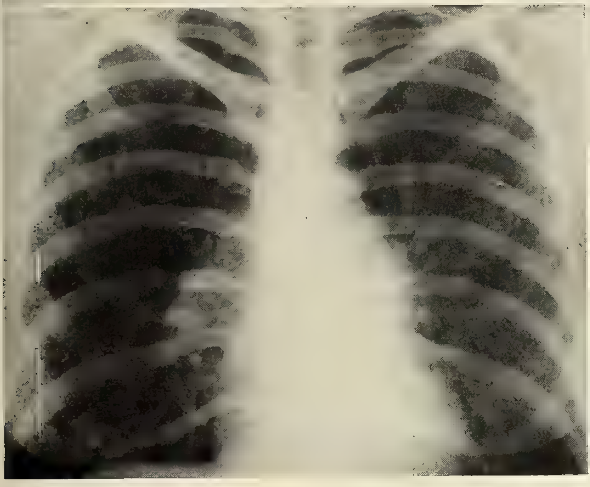

Fig. 7. (*Lower left*) Case 4. Radiograph taken March 31, 1948, a little over two months after onset of symptoms shows lesions similar to Cases 1 and 2 but not extensive. The two later cases showed resolutions at a similar period in the disease.

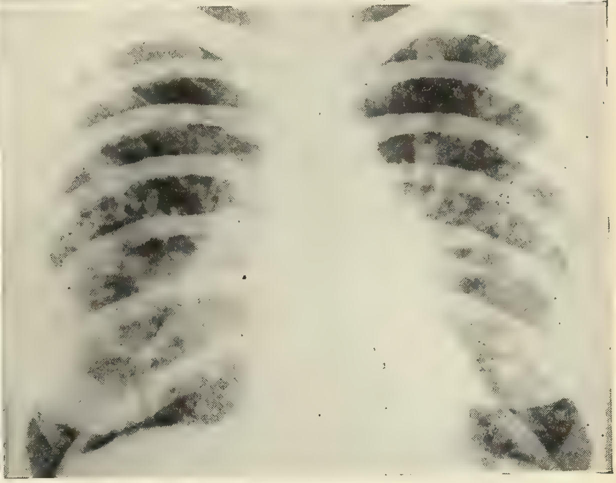

Fig. 8. (*Lower right*) Case 4. Radiograph taken June 30, 1948, near the height of disease, and five months after symptoms began.

ical findings of the respiratory system were well within normal limits. The laboratory and x-ray findings are summarized below.

She remained in the hospital thirty-two days and was sent home on bed rest except for bathroom privileges. Through June and July (1948) she showed slight improvement but still had night sweats and an afternoon temperature of 99.6° F. There was little change in August and September, and the last week of the latter month she was sent to the University Hospital for further consultation and study to see if the cause of this unusual condition could be found. From there Dr. Wesley Spink reported the following: Urine normal; blood: Hemoglobin, 13.7 gm.; white blood count, 6.700; polymorphonuclear, 63; lymphocytes, 29; mononuclear, 7; eosinophil, 1. Sedimentation rate was normal. The tuberculin skin test was negative; a skin test carried out with triple antigens of histoplasmin, blastomycin, and coccidioidin gave a one plus reaction. The vital capacity was 3200 c.c. Electrocardiogram showed a tendency towards right axis deviation; otherwise it was normal. X-ray showed a definite subsiding of the nodular lesion as compared to previous films. Dr. Spink gave the following impressions: "I reviewed the x-rays of the whole family with Dr. Leo Rigler and he is of the opinion that this family had a pulmonary fungus infection, probably aspergillosis. He felt the nodular type of lesion was in favor of a fungus infection rather than a complication of a virus pneumonia. I feel absolutely certain this patient will recover from her illness with little or no residual."

Following the consultation with Dr. Spink and Dr. Rigler (September, 1948) the sweats and cough continued to improve but she became extremely nervous, apprehensive and developed a severe insomnia which seemed to be related to her thoughts regarding sex and suppression of the sex impulse. She frequently expressed a fear of insanity and was greatly depressed

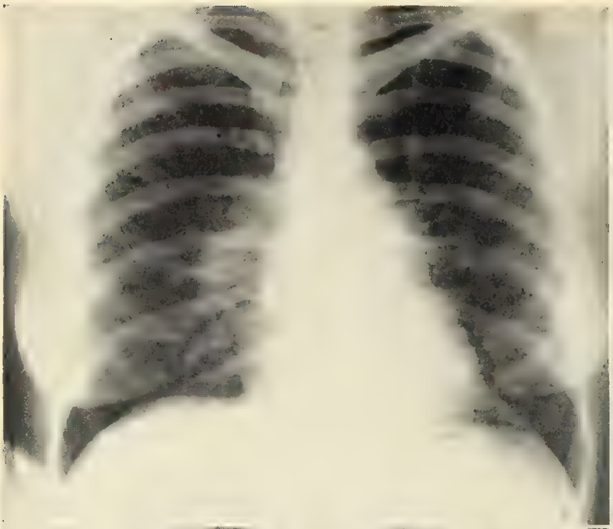

Fig. 9. (*Upper left*) Case 4. Last radiograph taken on March 13, 1950, twenty-five and a half months after patient became ill. Fibrosis and nodules remain. The hilar shadows are prominent.

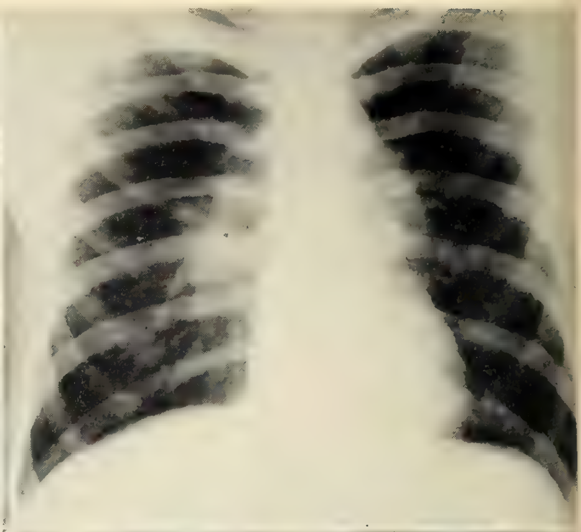

Fig. 10. (*Upper right*) Case 5. Radiograph taken April 13, 1949, about fifteen months after beginning of family epidemic. There are nodules as in other cases, and considerable hilar shadows.

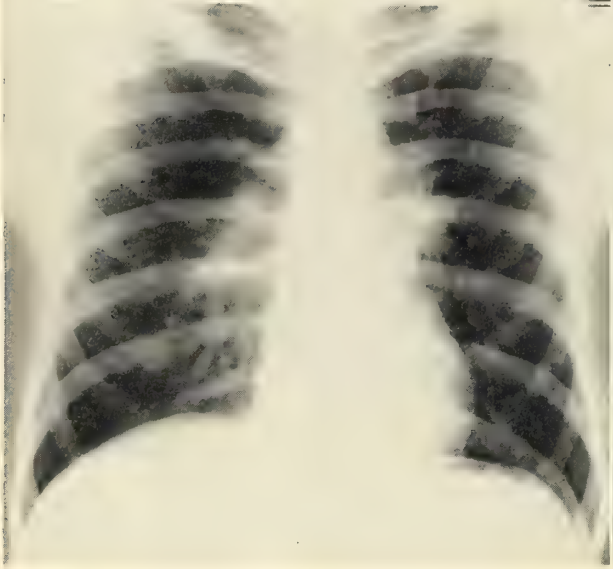

Fig. 11. (*Lower left*) Case 5. Radiograph taken June 25, 1949, as patient improved. This shows the hilar shadows are improved.

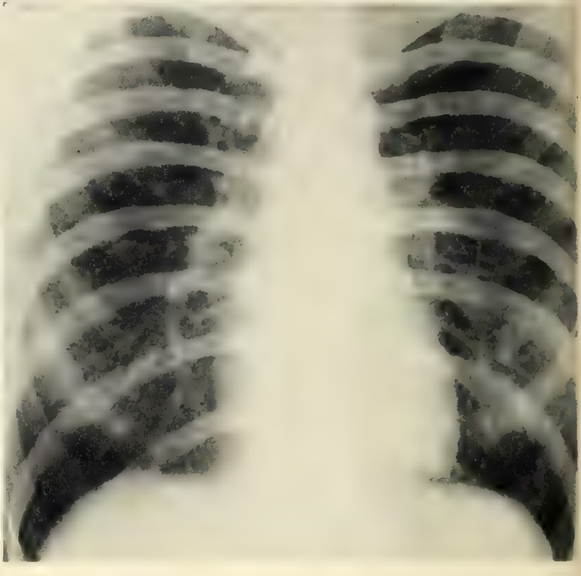

Fig. 12. (*Lower right*) Case 6. Radiograph taken March 1950. The patient was asymptomatic but showed fibrosis and nodules seen in other cases in family. This corresponds to findings in radiographs of Cases 1 and 4 taken at the same time.

during the winter of 1948-1949. She had a daily rise of temperature to about 99.5° F. until June, 1949. After that she became less nervous, gained a little weight (the loss had not been great) and the rises of temperature were less frequent. By the last of August, 1949, she admitted she was definitely improved and radiographs of the lungs confirmed this. By the last of November, twenty-two months after her illness began, she still had an occasional rise of temperature in the afternoon, as high as 99.7° F., had a slight aching pain in her chest and abdomen, a dry cough in the morning, but was able to be up most of the day and to do light housework in the farm home. She weighed 142 pounds which was about five pounds more than she weighed when she first came to the hospital. The nervous symptoms were much improved. The lungs were normal to physical examination and there were no sweats during the day or night. By March, 1950, she felt she was entirely recovered except that she admitted a mild dry cough on arising in the morning.

All laboratory tests used in Case 1 were tried and were devoid of positive results. The sputum could not be obtained.

Radiographs of the lungs showed the same nodular densities as in the other five cases and perhaps were more like Case 1 than any other member of the family. However, there was a difference in the progress of the pulmonary shadows. In Cases 1 and *2*, a peak of the disease seemed to be reached in about six to eight weeks, and at the end of the two months resolution began. In this case, the maximum findings in radiographs of the lungs occurred in June and July, 1948, about five or six months after the inception of the disease and there was no resolution noted until the last of August, 1948 (seven monhs). The last radiograph taken was in March, 1950, and showed nodular infiltration in the lung fields had almost cleared, some fibrosis and nodularity remaining but resolving. The hilar shadows were still prominent.

Case 5.—D. L., younger brother, aged twenty-four, was first seen in April, 1949, about fifteen months after Case 1. He complained of a racking nonproductive cough, had slight rises of temperature, felt weak and tired. His past history was significant. He was taken ill in January, 1948, three days after his brother R. L. (Case 1). At that time, he was in bed at home for one week, was convalescent at home for a week and had been well until the present complaint. A Mantoux skin test gave a positive reaction and radiographs of the lungs taken April 14, 1949, were strongly suggestive of the same nodular infiltration shown in Cases 1 to 4. The findings in Case 5 were much less extensive. He ran a temperature of 99.5° F. for six weeks but by the first of July, 1949, was afebrile and asymptomatic. The laboratory findings failed to throw any light on the family epidemic. His sputum was negative for acid-fast bacteria, and the study for the various fungus infections revealed nothing. This may well have been a new respiratory infection superimposed on the old one that had occurred simultaneously with the other five cases in January, 1948, and the new infection provoked a slight flare of the previous symptoms as the radiographs (Figs. 10 and 11) indicated the old process was there and had been for a considerable length of time. He still had a mild, dry cough in March, 1950.

Case 6.—M. L., the younger daughter, aged twenty-six, was not seen until March, 1950, over twenty-five months after the family epidemic occurred. She gave the history that she had been taken ill three days after her brother (Case 1) and was ill with something resembling the "flu" for over a week. She was in bed at home the greater part of ten days. She was married four months later and now has a baby ten months old, that is well so far as the mother and her family physician know.

A radiograph (Fig. 12) of the lungs on March, 1950, showed some fibrosis and nodularity of the lung fields, particularly on the right. These lesions are similar to the disease shown in radiographs taken of the other patients at this same time.

Treatment

Aside from the routine nursing care and symptomatic treatment accorded these patients, they were given first sulfadiazene or sulfamerazine in one gram doses every four hours. Later potassium iodine in saturation doses was given alone and with the sulfa drugs. Then penicillin and streptomycin were tried in the usual doses. The iodine was given on the ground that Monilia were present in the sputum. R. L. (Case 1) felt that he was benefited by the sulfadiazene potassium iodine combination, but my personal observations lead me to believe that all the treatment as given above was ineffective, except the bed rest and general nursing care.

Comment

All six members of the same family who constituted the entire household living on this farm had the same epidemic, pulmonary disease. It should be remembered that the family lived in a clean, well-kept farm home. R. L. (Case 1), aged thirty-one, became ill first and on the third and fourth day following, the other five patients were stricken. The symptoms were similar to influenza, consisting of a temperature rise of varying degree, a rasping nonproductive cough, chills and general malaise. The symptoms may be severe and acute as in Cases 1 and 2, or rather slow with an insidious onset as in Cases 3 and 4. Case 4 reached a peak five months after inception. Recovery from symptoms was slow in three of these patients, Cases 1, 2 and 4. A dry morning cough has persisted in three patients, Cases 1, 4, and 5, for over two years. Radiographs of the lungs show that resolution was slow in all patients followed during the twenty-five months of observation. The nodular infiltration was gradually replaced by linear fibrosis, noted in Cases 1 and 4. R. L. (Case 1), showed yeast-like organisms which were morphologically and culturally identical to Candida (monilia) albicans. In reviewing radiographs of the family, Dr. Leo Rigler decided that they had a pulmonary fungus infection, probably aspergillosis. He felt that this diagnosis was preferable to monilia or virus pneumonia. These cases may well have been aspergillosis with monilia present. Monilia albicans is the only fungus thought pathogenic to man (Smith of Duke) and is frequently an incidental finding in the sputum without causing any apparent disease.

Acknowledgment

Appreciation is expressed by the author to Drs. Wesley Spink, Leo Rigler, S. Friefeld and C. W. Parker for their interest and assistance in the diagnosis and care of these patients.

ACUTE INVERSION OF THE UTERUS

Report of Case

HARRY SHRAGG, M.D.
Elmore, Minnesota

MARCUS KEIL, M.D. and JOHN MIKKELSON, M.D.
Mankato, Minnesota

ONE of the difficulties encountered in country practice is treatment of serious obstetrical complications. Inversion of the uterus, though rare, may prove most difficult to handle, especially outside a hospital.

This condition probably occurs more often than is readily apparent from the figures usually quoted. Figures vary from Findley's estimates[5] ranging from an incidence of one in 400,000 to one in 23,000 labors, and McCullogh's[15] of one in 30,000 down to the statistics at New York Lying-In-Hospital,[15] where inversion of the uterus occurred once in 3,992 deliveries.

There are various degrees of inversion, designated respectively as incomplete, complete, and prolapse of the inverted organ through the introitus. It may also be classified as acute, subacute, and chronic inversion.[9]

There is a diversity of opinion as to the etiology of uterine inversion, but there are several factors involved, such as marked relaxation or thinness of the uterine walls, excessive pressure on the fundus, and traction on the umbilical cord. However, these factors do not explain the occurrence of inversion in those cases where the placenta is delivered with no assistance.[4] Its occurrence is also favored by fundal insertion of the placenta, and it may perhaps occur spontaneously as the result of intraabdominal pressure, or from mere weight of the intestines.[4,15] McKeown and Rankin[11] reported two cases where inversion occurred, in one case on the fifth postpartum day following prolonged efforts to empty a distended bladder, and in the other case on the thirteenth postpartum day while attempting to expel a difficult stool. Usually, however, inversion occurs immediately after delivery.

Complete inversion is usually simple to diagnose, but incomplete inversion may remain unrecognized, unless careful abdominal palpation reveals the absence of the fundus, or shows a crater-like depression above or behind the symphysis. Unexplained shock following delivery should suggest this possibility, and make imperative immediate vaginal examination by which means the diagnosis is readily established.

Mortality rates have been excessively high. If the condition is recognized and the uterus replaced immediately, the prognosis is good.[6] However, if strangulation or gangrene occur, the outlook is very grave, with the cause of death usually due to shock with or without hemorrhage.

Immediate vaginal reposition of the inverted uterus may be accomplished relatively easily at first, if the patient is not in shock;[4] however, if several hours have elapsed, it may be very difficult. If reposition is not possible, immediate treatment of shock is essential.

Barrett[1] and Henderson and Alles[7] in their articles state that shock with its attending morbidity and mortality can be avoided in the majority of cases. Barrett emphasizes and reemphasizes the point that there is usually a period immediately after the inversion when immediate manual reposition can be performed before severe shock and hemorrhage have taken place, but if one does not take advantage of this very short period of time, unfavorable circumstances develop extremely rapidly and dramatically with a very poor prognosis. An excellent prognosis follows immediate reposition of the uterus.

Clahr and Wurzbach[3] reported a case of their own and of only one other previously reported case where, coincidentally, the uterus was reduced following intravaginal packing for control of the bleeding. It was suggested that where vaginal packing was indicated, a large amount of packing be employed.

O'Sullivan[14] reported his experience in two cases, where the uterus was replaced by hydraulic pressure, when attempts at simple replacement failed, by distending the vagina to capacity by means of a dettol-and-proflavine douche, retained by blocking the vaginal outlet with his forearm aided by his assistant's hands.

Several operative procedures for acute and chronic inversion have been devised for vaginal and abdominal reposition of the uterus.[8,12,13]

Recently, however, more conservative management has been advocated, when immediate reposition was not possible, consisting of treatment of shock, control of bleeding and infection, and postponement of surgical correction of the abnormal uterus for some weeks.[2,10,12,16]

The following is the report of a recently treated case, which we present as an addition of one more case of this very uncommon obstetrical complication:

Mrs. O. H., aged thirty-five, para 2, was seen on August 16, 1948, and complained of vaginal itching, intermittent spotting, and "morning sickness" of three to four weeks' duration. Because of this intermittent spotting, she did not remember the exact date of her last menstrual period. Her periods previously were regular but always very scanty and of only two to three days' duration. Examination revealed the uterus to be enlarged in size consistent with a two months' pregnancy.

The patient's past history is as follows: On August 9, 1943, she was delivered of her first child, a full-term infant, followed by a normal convalescence. She began bleeding profusely after getting up on the ninth postpartum day, and was soon transferred to a larger hospital, exhibiting marked pallor, weakness, cold extremities, weak pulse, and a blood pressure of 78/?. The patient was given 500 c.c. of whole blood followed by 1,000 c.c. of 5 per cent glucose during the dilatation and currettage, which yielded a piece of placental tissue 3 x 4 x 5 cm., reported by the pathologist to be degenerative decidual and placental tissue. Postoperatively, her temperature ranged from 102 to 105 degrees, for which she received sulfadiazine until it fell gradually to normal on September 1. Following transfusion, because of a persistent anemia, she was discharged on September 7.

On November 2, 1945, she was delivered of an infant weighing 4 pounds 9 ounces after seven and a half months' gestation. Very little bleeding followed, but the physician who attended her previously, packed her uterus and transferred the patient to the same hospital, with the statement that "only half of the placenta was expressed following a normal delivery." With a suspicion of a retained placenta, a dilatation and currettage was performed, and the surgeon stated, "Many small fragments of placental tissue were removed, but no large pieces of tissue were found." The pathologist reported the tissue from the uterus to be blood clots, so we are left with the possibility either that the entire placenta was delivered initially, or that any remaining fragments were removed on the pack. Postoperatively, her temperature rose to 104° which quickly subsided with the administration of penicillin, and the patient was dismissed from the hospital on November 11.

At the time of her last pregnancy the patient intended to be delivered at the hospital and by the group to which she was referred before. As a result, she was followed prenatally by them as well as by myself. Her prenatal course was normal. On March 16, 1949, a flat plate of the abdomen revealed a breech presentation with the placenta on the posterior wall of the upper uterine segment. Attempted external version by them that day was unsuccessful.

At 2:15 a.m., on March 21, 1949, the patient's membranes ruptured following one pain, and almost immediately, pains of moderate intensity continued to recur every four minutes. Not having time enough to go to the hospital of her choice, she entered the local community hospital. Examination was negative except for the breech presentation. Using drop ether anesthesia and 1 per cent novocaine infiltration at the site of the left mediolateral episiotomy, a complete breech, S.L.A., was delivered without too much difficulty, at 3:45 a.m. The baby, a normal male infant, breathed spontaneously; bleeding was average.

A few minutes later, while I was attending the baby, the patient complained of more severe "labor-like" pains. The placenta was presenting at the introitus and was delivered easily with minimal gentle massage of the uterus, but it was followed by the completely inverted uterus, through the vagina. The placenta was separated a little and the uterus bled moderately. After giving the patient 1 c.c. of ergonovine intravenously, the placenta was removed without any apparent increase in bleeding. However, in about one minute, the patient began complaining of severe abdominal and back pain, at which time she turned pale, became pulseless, her blood pressure was unobtainable, and she became very dyspneic, fighting for air. There being only the nurse and myself present, the nurse administered oxygen while I replaced the uterus, still inverted, into the vagina, and concentrated my attention solely on treating the shock. I started plasma intravenously, since there was no blood immediately available, and hastily and temporarily repaired the episiotomy. The slight manipulation of the uterus aggravated the shock. The patient was also given morphine sulfate gr. 1/4 and atropine sulfate gr. 1/150 intramuscularly, another cubic centimeter of ergonovine intravenously, and 1 c.c. of pitocin intramuscularly.

After about an hour and a half, during which time the patient received 1,250 c.c. of plasma intravenously, the blood pressure finally began to rise to 70-80 systolic, pulse became perceptible but thready at 120 per minute, and she was breathing easier. She was then transferred, by ambulance, to a larger hospital 45 miles away, where we arrived about 6:15 a.m., her pulse and blood pressure remaining the same during the trip.

When we arrived at the hospital, the patient's blood pressure was 94/50, pulse was 120 and thready, hemoglobin was 44 per cent (17 gms. 100 per cent), and she was breathing fairly easily. The foot of the bed was elevated and her blood pressure rose to 110. While waiting for cross matching, the patient suddenly became dyspneic again, passed more blood vaginally, her blood pressure began to fall, and the pulse became weaker, so plasma was started. During the transfusion, she continued to do poorly and continued to bleed. It was then decided that the patient needed surgery, even though she was in shock, and she was taken to the operating room at 9:15 a.m.

A low midline incision was made and the inverted uterus converted to a normal position by grasping the uterus with a ring forceps, beginning at the edge of the crater until the apex was reached, and applying both traction from above and pressure from below. The ovaries and tubes had not been drawn into the crater, but there was marked hemorrhage into the left broad ligament with some difficulty in establishing landmarks. A subtotal hysterectomy was accomplished. Anesthetic used was ether by drop method as well as by machine. During the operation, the patient received 3,000 c.c. of citrated whole blood, 250 c.c. of plasma, and 500 c.c. of 10 per cent glucose in normal saline. Time for narcosis was two hours and thirteen minutes, and time for the operation was one hour and twenty-four minutes. No stimulants were given.

Her blood pressure which was unobtainable during the entire procedure, suddenly rose to 110/60 during the last fifteen minutes of the procedure, and her pulse suddenly slowed down to 80 to 92 per minute, but became intermittent and remained weak. When the patient was returned to her room, her hemoglobin was 66 per cent and respirations were 18 to 24 per minute. An additional 2,000 c.c. of normal saline was given intravenously, and within one-half to one hour, the patient passed about 1,000 c.c. of clear urine.

She was given penicillin and streptomycin and remained afebrile except for the day following the operation, when her temperature rose to 99.6°. The patient made an uneventful recovery, and was discharged on March 30, 1949, the ninth postoperative day.

Pathological examination of the uterus revealed no malignancy, but there was some intergrowth of the placental and muscle fibers consistent with retained placenta.

Summary

Acute inversion of the uterus is a rare obstetrical complication representing a very acute emergency. Its etiology and treatment are still controversial subjects. If immediately recognized, it can usually be manually reposed to its normal position relatively easily with an excellent prognosis; but if delayed for only a short time, the prognosis becomes very poor, with the necessity of shock being treated immediately, thereby delaying surgical reposition of the uterus for from several days to several weeks.

This is the case of a woman, with a history of having had a retained placenta with her first pregnancy and a clinical suspicion of a retained placenta with her second one, who had a breech delivery followed by an acute and complete spontaneous inversion of the uterus. Plasma and oxygen were the only things available for treatment of shock until the patient was transferred to a larger hospital, where she remained in shock for more than five hours, when operation as a desperation measure was attempted, and a subtotal hysterectomy successfully accomplished. The patient received about 3,000 c.c. of type A and type O blood without the slightest suggestion of renal impairment, and made a very rapid, successful, and uneventful recovery.

CHRONIC ILLS STUDIED

Chronic illness was designated "the nation's number one health problem" by a group of experts meeting in Chicago in May to discuss the prevention and treatment of such ailments as heart diseases, cancer, tuberculosis, hardening of the arteries, apoplexy, diabetes, arthritis, rheumatism, paralysis, and long-term disabilities resulting from disease or accident. Community-wide planning and action were recommended for the better control of chronic diseases.

Such diseases constitute one of the major health problems in Minnesota today, since they include six of our ten leading causes of death—heart disease, cancer, and intracranial vascular lesions being the first three, and diabetes, nephritis, and arteriosclerosis ranking sixth, seventh, and eighth, respectively.

The group meeting in Chicago was the Commission on Chronic Illness, established in May, 1949, by the American Medical Association, American Hospital Association, American Public Welfare Association, and American Public Health Association. Information on the chronic disease programs now in operation in various states and cities may be obtained from the Commission offices at 535 North Dearborn Street, Chicago 10, Illinois.—*Minnesota's Health*, June, 1950.

PAROXYSMAL TACHYCARDIA WITH ATTACKS OF UNCONSCIOUSNESS

Report of a Case

MELVIN D. MILLS, M.D., and HARRY L. SMITH, M.D.
Rochester, Minnesota

SYNCOPE with prolonged unconsciousness is an infrequent manifestation of paroxysmal rapid heart action. Seldom does it occur in youth in the presence of a normal heart. Such a situation came under our observation recently, and we felt it of sufficient interest to warrant a report. A review of the literature reveals only occasional mention of this particular occurrence.

Barnes[1] credited Savini with speaking of a syncopal form of paroxysmal tachycardia in 1912. In 1926, Barnes called attention to cerebral symptoms as manifestations of rapid heart action when he reported fifteen instances in a review of 104 cases of paroxysmal tachycardia. Four of these patients had syncopal attacks during seizures.

In reviewing the general subject of syncope, Williams[3] commented on a series of 100 cases of paroxysmal tachycardia. Fifteen patients had cerebral symptoms; of these, four experienced syncopal attacks; two had convulsions.

White,[2] without giving figures to indicate incidence, mentioned convulsions along with angina pectoris, congestive failure and persistent electrocardiographic changes as manifestations of paroxysmal rapid heart action.

Wolff,[5] in an extensive review of the cardinal manifestations of paroxysmal tachycardia, reported on a series of 253 patients. Of these, forty (16 per cent) experienced vascular collapse. Twelve patients of this group had normal hearts. Only one patient was in an age group under the fourth decade. The factor of age was not considered important, except that circulatory failure may be induced by somewhat slower rate in the aged than in younger patients. In 1942, in an earlier report, Wolff[4] reviewed six cases of central nervous system manifestations secondary to paroxysmal rapid heart action. Four of the patients had hypertension and two had coronary heart disease. Unconsciousness occurred as a transitory phenomenon in two cases.

Report of a Case

A farmer and former high school athlete, twenty-one years old, came to the clinic for evaluation of "convulsions." The patient was accompanied by his father (the father had witnessed three of nine attacks). During the three years prior to his registration at the clinic the patient had experienced nine attacks of unconsciousness, with loss of memory for the event. Sedative agents had been tried without benefit. An aunt had migraine. There was no familial history of allergy or of a convulsive disturbance. Previous infliction of trauma to the head was denied.

The initial attack had occurred in May, 1946. At the end of a 100-yard dash in high-school competition, the patient had collapsed and fallen motionless to the ground. In the ensuing half-hour to an hour, repeated efforts to arouse him were unsuccessful. He was flushed and breathed heavily. The pounding of his heart was noted by his coach, but no undue significance was attached to it. He recovered spontaneously. He was "groggy," but after ten to fifteen minutes felt able to remain at the field to watch further competition, and did so. The episode was dismissed as "runner's fatigue."

Five months later while the patient was playing basketball, a second episode occurred. The patient sensed that there was "something wrong" because his heart abruptly started to beat unusually fast. He left the game of his own volition; on reaching the sidelines he slumped to the floor. He was motionless, and remained unconscious for ten to fifteen minutes. When he aroused, he was assisted to the showers. The pounding of the heart continued for an additional ten to fifteen minutes, then suddenly and spontaneously returned to its usual rate.

A review of each subsequent episode then disclosed that rapid heart action and exertion or excitement were consistently present. At no time had there been loss of sphincteric control, an aura or an observed convulsive movement. No attacks had occurred during sleep. Injury had been limited to a laceration of the scalp received at the time of the initial attack when the patient had fallen on the cinders of the track. Readings of blood pressure had been taken during attacks, but they were not available.

On several occasions rapid heart action, characterized by a precipitous onset and sudden return to normal, lasting three minutes to three hours, had occurred without syncope. An occasional attack had been accompanied by a dull aching sensation in the left part of the thorax, without extension. During one attack the patient's local physician had been unable to terminate the attack by "neck or eyeball" pressure. An electrocardiogram made at the time of the attack was interpreted as show-

Dr. Mills is a Fellow in Medicine, Mayo Foundation, and Dr. Smith is in the Division of Medicine, Mayo Clinic, Rochester, Minnesota.

ing "the lower half of the heart beating twice as fast as the upper half." We did not witness an attack, nor were we fortunate enough to get an electrocardiogram during a period of rapid heart action. No other significant symptoms were elicited.

Examination revealed a husky, muscular, 6-foot, 177-pound youth in no apparent distress. The blood pressure was 114, systolic, and 80, diastolic, expressed in millimeters of mercury. The heart was not enlarged. No murmurs were heard. An occasional premature contraction was noted. Results of funduscopic examination and examination of the gross visual fields were normal. A neurologic examination did not reveal significant abnormalities.

Leukocytes numbered 6,800 per cubic millimeter of blood. The value for hemoglobin was 13.7 gm. per 100 c.c. of blood. Serologic tests gave negative results for syphilis. Urinalysis disclosed nothing significant. A roentgenogram of the thorax revealed the size and contour of the heart to be normal. An electrocardiogram showed a rate of 56, sinus arrhythmia with an occasional ventricular premature contraction, low amplitude QRS waves in leads I, II and III, inverted T waves in leads III, V-1 and V-3 and positive T waves in lead V-5. The pattern of the electro-encephalogram was essentially normal, with a regular and well-defined alpha rhythm of 10 cycles per second. There was no change with hyperventilation.

The patient was dismissed from our care on July 11, 1949, and advised to take 3 grains of quinidine four times a day. He was re-examined seven months later, on February 8, 1950. He had taken quinidine for four months, but had had none for three months prior to the last examination. At this time he complained chiefly of exhaustion, that his heart beat hard when he worked and that it was difficult for him to take a deep breath. He had had no episodes of fast heart or of unconsciousness since the first admission. We felt that his complaints at the time of his last admission were largely due to an anxiety state.

Summary

A case of syncope with attacks of prolonged unconsciousness, in which the heart was normal, has been presented. The clinical history and course were consistent with a diagnosis of paroxysmal tachycardia. The relative infrequency of occurrence of this manifestation of paroxysmal rapid heart action is of interest.

PHYSICIANS' OBLIGATION TO REDUCE COSTS

A tangible service to patients is within the control of many physicians; namely, lowered costs for laboratory work. Says the President of New York County Medical Society, in part:[1]

> Many a patient finds that his total bill for an illness may involve a very considerable charge for a battery of tests performed to accumulate a voluminous mass of diagnostic data. The new trend, too, is to have the patient undergo an entire "checkup" in diagnostic centers—even when critical illness is not at hand—as a measure of preventive medicine. This, again, is as it should be. Yet, again, there is no doubt that such a comprehensive series of laboratory procedures all adds to the price paid by someone for medical care . . . by the public, by health agencies, by the hospitals, or by the private patients.
>
> Without trying to fly against the advancing winds of medical progress, one may reasonably ask for a bit of reflection on the blanket orders sometimes issued for laboratory tests which—on second thought—promise to aid the diagnostician only slightly, which may sometimes by their very abundance confuse the issue, and which always increase the cost of illness for the patient.
>
> There is an understandable emphasis on elaborate clinical diagnostic procedures among younger physicians—fresh perhaps from a residency in a major university teaching hospital where they had only to lift a finger to have harassed technicians turn out the work. That was part of their postgraduate medical education and gave them the training and experience they will need later. Moreover, this reliance on the objective information thus available is a desirable thing . . . as information.
>
> But diagnosis is a mixture of information plus judgment. As these younger physicians come to work with their own patients in their private practice, they gradually learn that a second and a third look at the patient and their experience in physical diagnosis will often reap rewards in attaining the correct decision without confusing the issue with a host of laboratory data and at a considerable saving in cost to their patients. Never forget that the cost of medical care is a major issue of medicine today.
>
> One must add, immediately, that laboratory work, if it is truly needed, must never be sacrificed merely on the basis of cost. Admittedly, too, the margin between enough laboratory work and an overabundance is sometimes a narrow one. Nevertheless, for those who err on the side of ordering too much laboratory work it is well to remember that the world had good diagnosticians before they were born.[2]

While no one contends that the patient's financial interest is paramount, it is a definite and, we believe, a growing, obligation of the physician to assist in cutting costs in his patient's behalf wherever possible. This cannot be emphasized too often. Excessive fees and indiscriminate prescribing of expensive drugs, as well as unnecessary laboratory procedures, open the profession to justifiable criticism. There is, as Dr. Keating remarks, an art and science to the practice of medicine. The best over-all care of the patient—medically and economically—is the proper blending of the two.

Anything which physicians can do to help lower the cost to the patient without sacrificing the quality of medical care is most meritorious. Sensible planning in the numbers and types of diagnostic tests to be ordered for the patient is one starting place to achieve this end.—Editorial, *N. Y. State J. Med.,* July 1, 1950.

History of Medicine In Minnesota

MEDICINE AND ITS PRACTITIONERS IN OLMSTED COUNTY PRIOR TO 1900

NORA A. GUTHREY

Rochester, Minnesota

(Continued from June issue)

Elisha Wild Cross (continued)

His professional record was without blemish. Well educated, a student and traveler at home and abroad in the interest of professional improvement, he faithfully and generously gave his best in the nearly thirty years of his practice in Olmsted County. He held the affection of children and grown persons alike, and to his patients he was as much friend and temporal adviser as physician. He was a preceptor of medical students, medical examiner for fraternal lodges, and often a county physician. He served on the city board of health, for several terms as health officer, and in 1887 was a member of the Minnesota State Board of Health.

A founder of the early Olmsted County Medical Society, in 1868, he was in that year vice president, head of the committee on surgery and, with his brother and other members, a drafter of the first fee bill; when the society was reorganized in December, 1885, he was a charter member. Enrolled in the Minnesota State Medical Society from February 1, 1869, he was an active worker, several times a delegate to annual meetings of the American Medical Association. Under the "Diploma Law" of 1883 of Minnesota he held certificate No. 674 (R), dated December 31, 1883.

A progressing nervous disability that dated from the rigors of military service was aggravated by the demands of pioneer practice and in 1894 resulted in invalidism. A fall in January, 1899, while Dr. Cross was walking in his rooms, hastened his death, which occurred on the following November 21. At the funeral services the pallbearers were Dr. Cross's friends of many years: Drs. F. R. Mosse, H. H. Witherstine and Christopher Graham, of Rochester, and Dr. E. D. Stoddard, then of Stewartville, who had been one of his students. Special tribute to the memory of Major Cross was paid by Colonel John B. Sanborn, of the Fourth Minnesota Regiment: "One of the best of men and most faithful of officers"; and by the Loyal Legion, Commandery of Minnesota. Tribute to him as citizen, businessman and physician was paid by the Olmsted County Medical Society; the memorial, drafted by Drs. Witherstine, W. J. Mayo, and F. J. Halloran (of Chatfield), ended, "He was a good man. As such he will live in our memories."

Elisha Wild Cross was survived by his wife, Martha Peckett Cross, and by a son and a daughter. Mrs. Cross was a woman of culture and intelligence; she was a founder of the Rochester City Library in the sixties and until her retirement, in 1903, when her daughter succeeded her, she was a member of the board of directors; she died on February 19, 1907. The son, Maitland E. Cross, engaged in business in Rochester and later in Minneapolis; he was married in July, 1885, to Elva C. Daniels, of Rochester. Martha Helen Cross, the daughter, a graduate of Vassar College, was married on December 21, 1880, to Henry M. Nowell, a banker of Rochester, and spent her life in this city. She died on April 27, 1941, survived by a son, Reuben Nowell, of Rochester, and a daughter, Kate Theodate (Mrs. George Chute) Reid, of Rome, New York. The late Dr. G. C. Reid was from 1905 to 1908 a surgical assistant in what was soon to be known as the Mayo Clinic. The children of Dr. and Mrs. Reid are (1946) Dr. Henry Nowell Reid, a surgeon of Rome, New York, and Louise Reid Smith, of Gorham, Maine.

John Albert Grosvenor Cross (1870-1928) the sixth and youngest child of Dr. and Mrs. Edwin Childs Cross, was born in Rochester, Minnesota, on May 8, 1870, and there spent his youth and the first seven years of his professional career. His early education he acquired in the grade schools, high school and Niles Academy in Rochester; the degree of bachelor of science he received from the University of Minnesota in 1892 and, honor student and second in his class, the degrees of master of science and doctor of medicine from Northwestern University in June, 1895. One of four graduates appointed on the basis of scholarship to internship at Mercy Hospital, Chicago, under Dr. Frank Billings, he refused the opportunity because of his mother's failing health, and returned to Rochester, accompanied by his wife, to begin general medical practice. He was married on September 4, 1894, to Frances Montgomery; Mrs. Cross was a native of St. Cloud, Minnesota, a graduate of the University of Minnesota in 1891 with the degree of master of science, and previous to her marriage was a teacher and a supervisor of primary instruction in the schools of Saint Paul.

Dr. Cross became a member of the Olmsted County Medical Society in 1895, was secretary and treasurer in 1896-1900, and president in 1902. In 1897 he was enrolled in the Minnesota State Medical Society and in 1898 in the Southern Minnesota Medical Association.

An outstanding feature of his seven years as a physician in Olmsted County was his study and clinical application of the x-rays, which were announced to the world by Roentgen in 1895. The first physician in Rochester to give serious attention to the discovery, by the early summer of 1896 Dr. Cross had assembled a workable "apparatus for using x-rays in photography"; his first successful picture, which had wide publication, was of his wife's hand; Mrs. Cross sat for three hours while the picture was made. At the August, 1896, meeting of the Southern Minnesota Medical Association he gave a showing of x-ray pictures in diagnosis. His new science repeatedly was put to clinical use by local surgeons to determine skeletal defects and to locate foreign bodies. Taken with his sound professional knowledge and personal integrity, his initiative and ability in roentgenography attracted attention in the Northwest and brought him due recognition.

In October, 1902, relinquishing his practice to Dr. John E. Crewe, who had been his partner since May of that year, Dr. Cross left Rochester with his family for Europe, where he spent a year, studying in many different cities but chiefly in Vienna with Edmund von Neusser. On his return to Minnesota he began his career as an internist in Minneapolis. The detailed story of his subsequent work belongs to the history of medicine in Hennepin County.

Dr. Cross was a cultured gentleman of personal charm, sympathy and warm sense of humor, a musician and student, a member of the Episcopal Church. He was a skilled physician, a sound writer on medical subjects, a worker for medical education and organization and the elevation of medical ideals and standards. For several years he was on the teaching staff of the medical school of the University of Minnesota; long on the clinical staff of four hospitals, Northwestern, Hillcrest, Abbott and St. Mary's, some time with St. Barnabas Hospital, and chief of the medical staff of the City Hospital. He was a member of the college fraternities Chi Psi and Nu Sigma Nu (medical) and of many medical societies, county, state, national and special.

John Grosvenor Cross died on March 3, 1928, at the age of fifty-seven years, from a cerebral hemorrhage brought on by an automobile accident, and was survived by his wife, a daughter and two sons. In 1946 Mrs. Cross and Miss Louise Cross, the latter a sculptor, medical illustrator and writer, were living in New York. Grosvenor Montgomery Cross, a mechanical engineer, was in New York and Connecticut, in work that took him into Latin America; Roderic Marcy Cross, an engineer, was in Torrington, Connecticut, a member of the board of directors of Torrington Manufacturing Company; during World War II both sons were engaged in defense work. Mrs. J. G. Cross died in New York on February 20, 1949. She was survived by the three children and by nine grandchildren, six girls and three boys, of whom one was John Grosvenor Cross.

Nathaniel (commonly **Nathan**) **S. Culver,** a small, energetic man, who was born in Rock County, Wisconsin, about 1843, came to Minnesota in 1866 and to Rochester in early 1867. His first announcement, published in the *Rochester Post* of June 15, 1867, served to introduce him:

> Dr. N. S. Culver, Eclectic Physician. Office: Broadway, opposite Heaney's Brick Block. Special attention given to Chronic Diseases, such as rheumatism, liver complaint, throat diseases, dyspepsia, bronchitis, diabetes, diseased kidneys, scrofula, weak spines, asthma, loss of voice, and nervous debility.
>
> Mild medicinal remedies will be used, and each patient will be insured the proper treatment, whether by Magnetism, Electricity, or Eclectic Medicine.
>
> Tape worms successfully removed. A cure warranted.
>
> Patients at a distance can send for circular and copy of "Questions to Invalids." References: Dr. A. Castleman, Milwaukee; Dr. R. W. Hathaway, Milwaukee; Dr. N. G. Storrs, Milwaukee; E. G. Crandall, Esq., W. S. Alexander, Esq.

In September, 1868, Mr. J. D. Blood, an established druggist of Rochester, took Dr. Culver into partnership in the Union Drugstore on Broadway. After Mr. Blood's death in 1870 Dr. Culver carried on the expanded drugstore with great success, first alone, and later with his brothers George and John. He traveled considerably and often brought back objects of interest, which he exhibited in the drugstore; on his return from a clinical visit to Chicago in November, 1871, he displayed a collection of curious specimens of fused metal and glass from the ashes of the Great Fire. Dr. Culver's drugstore, incidentally, was one of the pharmacies in Rochester in which Henry W. Wellcome (later Sir Henry, of London, England) worked for a time as a clerk. An elderly lady of Rochester, then a young girl, has said of Henry Wellcome, "I didn't know the word *personality* then, but he had personality if any one ever did."

Dr. Culver was among the eclectic practitioners who met in Owatonna on May 26 and 27, 1869, to organize the Minnesota State Eclectic Medical Society; he was elected recording secretary and at the next annual meeting, in June, 1870, also at Owatonna, he was re-elected. Although Dr. Culver thus furthered eclectic medicine, and made trips to Chicago and Philadelphia to attend medical lectures for the improvement of his knowledge, it is believable that his undoubted success and popularity were due as much to his personal traits and his activities as business man, church worker and ardent exponent of temperance, as to his skill as a physician.

Nathaniel S. Culver was married on May 19, 1870, to Mattie A. Nicholson, only daughter of B. Nicholson, of Watertown, Wisconsin, and brought his wife and his father-in-law to a new home at the corner of Grove and Third Streets. Mr. Nicholson died in April, 1871; Mrs. Culver died in August, 1872, at the age of twenty-nine years, leaving an infant son. In the winter of 1873-1874 Dr. Culver because of his own failing health and the child's illness, sought the salubrious climate of Colorado, which had begun to attract popular attention, in company with other citizens of Rochester.

By October, 1874, he was established in Colorado Springs, although he continued for some years to own his drugstore in Rochester, and thereafter for seventeen years, during which he made periodic visits in Rochester, reports came back of his multiple interests and his prosperity. He discovered fire opals near Colorado Springs; struck a bonanza gold vein, the Ute Pass Lode, at Manitou; organized a stock company for silver mining. In 1875 he presented to the Rochester High School a large collection of mineralogic and geologic specimens that he had gathered in Colorado and had exhibited in the Union Drugstore in Rochester. In 1876 he was candidate for alderman on the temperance ticket; in 1878 he was elected state treasurer of Colorado.

On January 30, 1891, the *Rochester Post* made the following announcement: "Dr. Nathaniel S. Culver, at one time a resident of this city, died recently at Colorado Springs, Colorado, aged forty-eight years. His business in that state was that of mining director. For some years he was one of the directors of the First National Bank of that city and was president of the First Congregational Church of Colorado Springs."

Eugene C. Davis, son of Mr. and Mrs. Ezra Davis, of Viola Township, Olmsted County, and at one time a medical student under Dr. Hector Galloway, of Rochester, returned home from New York City in March, 1876, a qualified doctor of medicine. After practicing in the community of Viola a few weeks, he rented his farm (*Rochester Post,* April 15, 1876) and removed to the village of Plainview, Wabasha County, to enter partnership with Dr. Nathaniel S. Tefft, a highly respected pioneer physician.

Dr. Davis was married on January 2, 1881, to Miss Mattie Champine, daughter of Mr. and Mrs. C. Champine, of Plainview.

The career of this young physician was cut short by his untimely death, in Plainview, from typhoid fever on November 27, 1881.

A **Dr. Davis,** of Rochester, in April, 1885, cut a cancer from the lip of a citizen of Marion. "It was a neat job and left a little of the lip." Other than this item, information about this Dr. Davis is lacking.

Paul G. Denninger (1848-1927), a homeopathic physician, practiced medicine in various localities of southern Minnesota between 1870 and 1890. Eckman mentioned him, in 1941, in an article on homeopathic and eclectic medicine in Minnesota. A sketch of this practitioner appeared in an article on the history of medicine in Fillmore County (Guthrey).

A native of Germany, born in 1848, Paul G. Denninger in 1862 came with his parents to the United States. In 1870, twenty-two years old and a physician, he arrived in Minnesota, and in Eyota, Olmsted County, began the practice of medicine, succeeding Dr. Benjamin F. La Rue. His office first was in the building of C. S. Andrews, later over the Wagner shoe store, and finally in his residence on the corner of Fourth and Lafayette Streets, opposite the Presbyterian Church.

In Eyota Dr. Denninger was married on June 12, 1871, to Susie A. Wagner, of Eyota, daughter of the local shoe merchant. In 1876 he removed to Spring Valley to enter partnership with his brother-in-law, Dr. C. H. Wagner. After a few years in Fillmore County during which he took a degree, in 1879, at the Hahnemann Medical College and Hospital of Chicago, he settled in Faribault about 1881. From Faribault he removed to California in 1890 and there practiced successfully at various places; he died in San Jose on December 10, 1927.

William M. Dodd (1853-1883), of brief professional career, was born in Cortland County, New York, on December 20, 1853, the eldest of the three children of Isaac Dodd and Margaret Johnston Dodd. Both Isaac Dodd and his wife were natives of Cumberland County, England, who came to the United States in their youth; they were married in Elgin, Illinois, later farmed in Cortland County, New York, where Isaac Dodd first had settled, in 1849. In the spring of 1855, members of a group of travelers seeking new homes, they arrived in southern Minnesota and opened a farm in section 23, Kalmar Township, Olmsted County. Margaret Dodd died in 1858, and in 1862 Isaac Dodd was married to Helen Ranson, a relative of the Ranson family of Dodge County, three members of which have been well known in Minnesota medicine. Of this second marriage there were ten children, of whom four were living in 1883.

William Dodd, after attending the district school near his home, studied academic branches at Niles Academy in Rochester and medicine under Dr. Hector Galloway of that city, preliminary to a formal medical course. In March, 1880, he returned home, a qualified graduate of the Chicago Medical College, and for the next three months practiced medicine in Byron, as locum tenens for Dr. Isaac Hall Orcutt, who was taking a postgraduate medical course at the University of Pennsylvania. From Byron Dr. Dodd went to Austin and soon after to Brownsdale, also in Mower County, where he practiced until his health failed: an attack of lung fever in August, 1882, was followed by tuberculosis. In January, 1883, with his wife, Nona Hitchcock Dodd, to whom he had been married at Milan, Minnesota, in July, 1880, he went to Napa City, California, the home of Mrs. Dodd's parents, seeking a beneficial climate. The only child of the young couple, a little boy, died en route. Dr. Dodd's death occurred at Napa City on April 20, 1883.

William Doms (1858-1928), who was born on July 15, 1858, and who held an exemption certificate to practice medicine in Minnesota under the medical practice act of 1887, died in Woodstock, Minnesota, on July 21, 1928, after a residence there of twenty-six years. A note has appeared that he was married on March 19, 1879, to Anna Ingle, of Rochester, Olmsted County, and that in the following October he removed to Pipestone.

Rollo Carlton Dugan (1865-1927), a son of Elijah S. Dugan and Calista Griffis Dugan, was born in Eyota Township, Olmsted County, on February

12, 1865. Elijah Dugan was a native of Ohio, Calista Griffis, of New York. After their marriage Mr. and Mrs. Dugan in 1857 went to Stark County, Illinois, where their two elder sons, Nathan F. and Charles, were born. In 1862 the family came to Minnesota and settled on a farm near Eyota. At one time Mr. Dugan operated a traveling merchandise van; in the seventies this rig, an enclosed vehicle drawn by a pair of sturdy roan ponies with black manes and tails, was a familiar and welcome sight to farm families in various parts of the county. Mr. Dugan and his wife in their last years made their home at Compton, California.

Rollo C. Dugan went to district and village schools of Eyota Township, to high school in Rochester, and to the University of Minnesota. He took his degree of doctor of medicine in 1890 and returned to his native locality, with his headquarters in Dover, to begin a general medical and surgical practice. In near-by Eyota, from 1873 to 1892, Dr. Augustus W. Stinchfield with distinguished success carried on a practice that was for those years unusual in size and scope. When, in February, 1892, he removed to Rochester on the invitation of the Drs. Mayo to join their group, young Dr. Dugan transferred to Eyota, to take the older doctor's practice and to carry on in his tradition. At the same time Dr. Dugan held his practice in Dover, avowedly for the benefit of his undergraduate friend, Melvin S. Millet (M.D., University of Minnesota, 1895), whom he encouraged and coached in the study of medicine.

On February 20, 1892, Rollo C. Dugan was married at Dover to Isabelle Styles, daughter of William and Elizabeth Styles, pioneer settlers in Dover Township. Mrs. Dugan's sister Agnes was Mrs. Nathan F. Dugan; a second sister, Miss Lucy Styles, a trained nurse, was Dr. Dugan's personal assistant for more than thirty years. Dr. and Mrs. Dugan had four children: Rollo C., Jr., Catherine, Nathan Clay, and Melvin Millet.

Well-qualified, well-liked, ethical and progressive, with a bent for surgery, Dr. Dugan became an outstanding member of Olmsted County's medical profession. He was of medium height, heavy, possessed a keen sense of humor and a notably guarded tongue. When he started practice, it was said locally that he would not be a success because he would not talk; when unduly pressed for information about a case, his defense mechanism was to mutter amiably and indistinctly, edging the while to the door and, apparently about to make a decisive statement, make his escape. It is recalled by his relatives that Dr. Dugan spent as many mornings as possible each week in Rochester observing and studying the work of his friends Drs. W. J. and C. H. Mayo at St. Mary's Hospital; he always said that he learned surgery from the Drs. Mayo. By 1896 Dr. Dugan had equipped part of the old Dugan home in Eyota, which was his residence and office, as a small surgical hospital, although it was not until October, 1900, that he increased its capacity to eight beds and called it the Eyota Hospital.

Dr. Dugan was a member of the Olmsted County Medical Society, the Southern Minnesota Medical Association, the Minnesota State Medical Society, the American Medical Association, and other professional groups, among them the American Association of Railway Surgeons. He took an active part in the work of all, serving on committees and contributing scientific papers on a wide range of subjects. Concerning one paper an incident, still cited, occurred at a meeting of the American Medical Association, when Dr. Dugan was to make his first appearance before the surgical section of that assembly: Dr. W. J. Mayo was chairman of the section, Dr. Dugan was on the program for one o'clock, Dr. Mayo had introduced him and he was starting to read, when there was a rush at the door and a murmur through the hall that Dr. ...., a famous surgeon of Chicago, listed on the program much later, was here, wished to read his paper now, could not wait. Dr. Dugan, paper in hand, was much embarrassed and turned to leave the platform as the Chicago surgeon walked confidently forward amid enthusiastic applause. Dr. Mayo quietly announced once more that Dr. Rollo C. Dugan, of Eyota, Minnesota, would now give his paper, and the country surgeon gave it.

Dr. Dugan was health officer and county physician, postmaster at Eyota from 1903 to 1904, and was active in civic and social organizations. He was a Republican, a member of high standing in Masonry in St. Charles and Winona lodges. He drove fine horses, was a member and founder of the Eyota Driving Park Association, enjoyed fishing, was a good shot and annually went hunting in the years when prairie chickens were plentiful in Minnesota and the Dakotas.

In 1913 Dr. Dugan and Dr. Dorr F. Hallenbeck, then of Goodhue, planned to enter partnership for practice in Nebraska, and Dr. Dugan was to be replaced in Eyota by Dr. Fred L. Smith, then of Chatfield (since 1917 Dr. Smith has been with the Mayo Clinic in Rochester). Because of unavoidable delay in arrangements, Dr. Dugan urged Dr. Hallenbeck to take an opportunity that offered with the Drs. Mayo at Rochester. He himself was in Valentine, Nebraska, briefly, later was a few months in Winona. In 1914, "after making a success of a surgical hospital for eighteen years in a town of less than 500 inhabitants" (Eyota), he settled in Ottawa, Kansas, where he spent the remaining thirteen years of his life in active surgical practice, the greater part of that period with the Ransom Memorial Hospital. He was a member of the Franklin County Medical Society and the Kansas State Medical Society and continued to be a worker for civic improvement.

Rollo Carlton Dugan died at Ottawa, Kansas, on June 10, 1927, aged sixty-two years, from carcinoma of the jaw and throat, survived by his wife, four children, several grandchildren, and nieces and nephews. The one daughter died some years later. In 1945 Mrs. Dugan and her son Melvin Millet Dugan, a chemist, were in Chicago; Nathan Clay Dugan was in Wichita, Kansas; and Rollo C. Dugan, in Fort Wayne, Indiana. A nephew, William J. Dugan, was a resident of Rochester, Minnesota.

M. N. Dyer, aged forty years, died in Rochester, Minnesota, on April 18, 1863. The *Rochester City Post* of May commented as follows: "Dr. Dyer was a physician of large practice and great skill and during his brief residence in this city he had won by his generous impulses and warm heart a large circle of friends."

(To be continued in the August issue)

President's Letter

NO AGENDA OF PROMISES

Totalitarianism, it has been said, begins with promises, ends with control. The American people have been looking closely at this historical truth during the last several years, as promises of security have beckoned them down the path to government control.

Dominant have been the promises of universal medical care, promises which apparently entail no thought or effort on the part of the recipients in making them reality.

The American Medical Association, meeting in annual session at San Francisco, made no promises, offered no effortless solution to the problems that remain in the field of medical care and those that will emerge with the shiftings of economic, sociologic and political developments. But in seventy-four definitive and aggressive actions, American medicine offered the public an opportunity to work with the profession in raising even higher the standards and application of medical science. Medicine demonstrated again its acceptance of the responsibilities of leadership contingent upon the practice of this profession.

This recently concluded meeting of the nation's physicians has been an historic one, particularly from the standpoint of public interest and participation. As Dr. Elmer Henderson, AMA's new president, said June 27:

> "There is a vital reason for this new policy. Our affairs are no longer just medical affairs. They have become of compelling concern to all the people.
>
> "American medicine has become the blazing focal point in a fundamental struggle which may determine whether America remains free, or whether we are to become a Socialist State, under the yoke of a government bureaucracy, dominated by selfish, cynical men who believe the American people are no longer competent to care for themselves."

We have taken the public into our confidence, setting forth our ideals, our objectives, the methods we feel to be most effective, as well as most analagous to the traditional freedom-respecting and evolutionary action that has characterized this nation and made it unique in progress and strength.

The results of combined medical thinking at the AMA meeting are of profound importance, and every physician should familiarize himself with the policies which have been developed so that these policies will culminate in early, unified action.

F. J. Elias.

President, Minnesota State Medical Association

STATE OFFICERS ELECTED

At the annual meeting of the Minnesota State Medical Association, convened at Duluth June 12, 1950, the following officers for 1951 were elected by the House of Delegates:

President-Elect—Dr. J. F. Norman, Crookston.

First Vice-President—Dr. Willard White, Minneapolis.

Second Vice-President—Dr. A. E. Brown, Rochester.

Secretary (reelected)—Dr. B. B. Souster, Saint Paul.

Treasurer (reelected)—Dr. W. H. Condit, Minneapolis.

Speaker of House of Delegates(reelected)—Dr. C. G. Sheppard, Hutchinson.

Vice-Speaker of House of Delegates (reelected)—Dr. Haddon Carryer, Rochester.

Dr. John Francis Norman, the newly chosen president-elect is a native of Minnesota and received his medical degree from Hamline Medical College in 1907. He has practiced surgery at Crookston since graduation and has been active in local and state medical affairs, having served on numerous state medical committees.

TERRAMYCIN

A NEW ANTIBIOTIC, terramycin, has been added to the list of agents used in the treatment of infectious diseases. Terramycin was isolated from cultures of Streptomyces rimosus and first reported by Finlay and his colleagues in January of this year. Its name was derived from the fact that the growth presented a cracked appearance on the surface of the agar medium. Terramycin is a yellow crystalline amphoteric substance which is highly stable in the dry form. It was established that this antibiotic possesses antimicrobial activity against a wide range of pathogenic organisms, and at the same time a low degree of toxicity in laboratory animals was demonstrated. In March, Hobly and co-workers published reports containing more detailed information concerning the antimicrobial activity of this drug. It was found to be effective against a wide variety of aërobic and anaërobic Gram-negative and Gram-positive bacteria and certain of the rickettsiae. The observation that this substance possesses an extremely low degree of toxicity was again affirmed. Extensive studies on absorption and excretion in animals reported at the same time indicated that terramycin is absorbed readily after either oral or parenteral administration and is excreted in a biologically active form. The first studies directed toward the use of terramycin in man were reported in April from the Mayo Clinic. It is apparent from this report that terramycin is readily absorbed after oral administration of 1 gm. and that rather constant blood levels are maintained for approximately six hours. After this six-hour period there is a gradual decline with minimal activity still demonstrable in some instances after twenty-four hours. The therapeutic adult dose was therefore established at 1 or 1.25 gm. administered orally every six hours.

Terramycin for intravenous use is under investigation at present. It was found that this antibiotic diffuses readily through the placenta into the fetal circulation and into the pleural fluid; however, unlike aureomycin, little or no terramycin crosses the barrier between the blood and the brain.

Large quantities of terramycin are excreted in the urine. Smaller but significant amounts appear in the bile. When administered by the oral route large amounts are not absorbed but are excreted in the feces.

Clinical experience based on the report by Herrell and co-workers and on recent reports in the *Journal of the American Medical Association* indicate that this antibiotic is therapeutically effective in a wide variety of infectious diseases. In this respect its action is similar to that of aureomycin. It is apparent, however, that although these drugs are similar in many respects there are significant differences. Many of the common infections of the upper part of the respiratory tract including septic sore throat, acute follicular tonsillitis and acute laryngotracheitis have responded to its use. Terramycin is extremely efficient in the treatment of the bacterial pneumonias, and the results in whooping cough are promising. Infections of the urinary tract due to susceptible organisms are rapidly brought under control; these organisms to date include Escherichia coli and Aerobacter aerogenes. Undoubtedly, with further clinical experience more of the bacteria causing infections of the urinary tract will be added to the list of those already mentioned as being effective. Similarly, pyelonephritis responds in a satisfactory manner to the action of this drug. Septicemia owing to Escherichia coli and bacteroides has been treated with excellent results. Terramycin produced no demonstrable effect in one case of herpes zoster. It is certain that as clinical experience with this new antibiotic widens it will be found that its therapeutic range of activity is much greater than indicated above.

Terramycin is a relatively nontoxic substance. This statement is supported by the fact that to date the only toxic reaction ascribed to its use is occasional gastrointestinal irritation manifested by nausea and, on occasion, vomiting. Usually these symptoms can be obviated by the simultaneous administration of milk. Furthermore, it has been established that milk does not interfere with the absorption of this drug.

W. E. Wellman, M.D.

CLOAKING OF SIGNS AND SYMPTOMS BY CORTISONE AND ACTH ADMINISTRATION

THE wonder drugs, Cortisone and ACTH, are finding a limited place in therapy. There is accumulating evidence that the acute reaction to rheumatic fever may be limited in extent of invasion and distortion (valves of the heart or its musculature); and the obvious allergic reactions of hay fever are held in abeyance while the season passes over. No one, so far, has indicated clearly whether this withholding of the symptoms and signs of such definite entities as rheumatic fever has any limiting influence upon their natural course, or the development of natural remissions and immunity. Whatever these sequences are that restore body balances and constants in the sense of Walter B. Cannon's homeostasis, the supposition has been that this interaction of attacking agent (whatever type) and the mechanisms of bodily resistance (fever, leukocytosis, connective tissue reaction and healing) represents on the whole a salutary conflict.

Now come reports from various sources, conspicuously from McGill University,* Montreal, Canada, presenting some unlooked-for side-effects in terms of the masking of common disease entities and the possible inhibition of healing due to faulty collagenous tissue activity. Two instances of diffuse peritonitis developed while the patients were under treatment with ACTH. The first was an instance of Hodgkin's lymphoma where an upper respiratory infection developed into a questionable pneumonia of the right lower and middle lobes. While the patient's symptoms and reactions were mild, nevertheless at post-mortem a "heavy growth of pneumococci" was cultured from the blood of the heart and the fluid in the peritoneum was part of a diffuse peritonitis. In another instance, a patient under treatment with ACTH for severe asthma suffered a vague abdominal attack where it was found that an ulcer of the duodenum had perforated.

Such experiences may call for extra watchfulness in the exhibition of Cortisone and ACTH. Indeed, our entire concept of nosology may need revamping. When the symptoms of pneumonia abate meanwhile systemic bacteremia develops; and when there is a response to conditions as different as is Addisonian anemia (responding in an exacerbation quite as definitely as does the rheumatoid arthritic), it would appear that these novel agents need the closest checking, not only when used therapeutically but in investigative research.

E. L. Tuohy, M.D.

A ROSE BY ANY OTHER NAME

IN AN EDITORIAL entitled "Defeat of Reorganization Plan No. 1," which appeared in our September, 1949, issue, we explained how Plan No. 1 was defeated by vote of the Senate on August 16, 1949, largely, we believe, as a result of what amounted to a pilgrimage to Washington by representatives of the State Medical Associations throughout the nation. Plan No. 1 provided for the establishment of a Welfare Department in our Federal Government to be headed by a layman and to include social security, education and most health activities of the Federal Government. The medical profession has been adocating for years a separate Federal Department ncompassing the health activities of the Federal overnment with a medical man in charge as a ember of the Cabinet. We believe that the ealth activities of the Federal Government affect nough people and are important enough to arrant such treatment as recommended by the ask Force of the Hoover Commission. We elieve that to include health activities with social ecurity and education at present with the idea of ater effecting a separation is not likely to be ccomplished, and the profession does not want a ayman and someone who is so obviously a ocialist, like Oscar Ewing, to handle governnental health activities.

---

*Beck, J. S., et al: Canadian M. As. J., 62:423, (May) 1950.

In spite of the opposition of the medical proession—so forcibly expressed in Washington ast August—the President has submitted his eorganization Plan No. 27 to Congress which is ubstantially the same as last year's Reorganizaion Plan No. 1 and, as a matter of fact, the ame as S. 140 in the 80th Congress. Does the President think the profession has changed its nind, or does he expect to wear us down until we are ready to cry quits? This matter of legisation was important enough last summer to warrant a special trip to Washington of repreentatives from the State Medical Associations to nake our ideas known. Such action is expensive, out if need be will undoubtedly be repeated.

* * *

As we go to press, the announcement comes that the House, on July 10, vetoed President Truman's proposal for a new Department of Health, Education and Security by the overwhelming vote of 249 to 71. On the same date, the Senate executive expenditures committee voted 6 to 3 to reject the new department and was set to kill the bill on July 12. It will not be necessary now for the Senate to take action. It remains to be seen whether this demonstration of opposition to President Truman's plan which was the same as that defeated last August under another name will prevent future attempts to cram this undesirable legislation down the throats of the people contrary to the recommendation of the Hoover Commission and the advice of the medical profession.

It should be noted that Representatives McCarthy and Blatnik voted for the proposal and Representatives Andersen, Andresen, Hagen, Judd and O'Hara were opposed.

GENERAL PRACTICE AND GP

GENERAL practitioners outnumber specialists two to one and constitute the backbone of the profession. It merits repetition and emphasis that the challenge of general practice from the standpoint of service to humanity and professional interest, though less spectacular, is fully as appealing as that of specialization. The impossibility of acquiring and keeping up with the mass of medical knowledge already recorded and published yearly has necessitated specialization. Only the most talented and industrious specialist can hope to keep up with the literature in his limited field. The general practitioner must be a voracious reader, indeed, and be able to pick and choose and digest the medical literature available and suited to his needs in order to keep pace with medical progress. This requires an intelligence of no mean caliber.

The general practitioner, especially if he be located in a rural district, probably has the opportunity of knowing his patients better and for longer periods of time than can the specialist. Knowing more of a patient's home environment, habits, and peculiarities is a distinct advantage to the patient and his physician in gauging the significance of early symptoms. Such knowledge has not infrequently warded off unnecessary treatment, both surgical and medical.

In recent years, definite steps have been taken not only to recognize the importance of the place of the general practitioner in providing medical care but in raising their quality. Special postgraduate training for those planning to take up general practice, refresher courses, the mid-winter AMA meeting devoted to the general practitioner, a general practice section in the AMA, and finally, the formation of the American Academy of General Practice devoted to the improvement of the general practitioner, may be mentioned.

The American Academy of General Practice held its second annual meeting at St. Louis in December, 1949. This meeting was attended by over 5,000 general practitioners who exhibited even more enthusiasm and earnestness than at the first meeting in 1948. For some time it has been felt that the Academy should publish its own journal devoted to the needs of the general practitioner. The first issue in attractive format appeared in April, 1950. Just as Volume I was ready to go to press, the editor, Dr. F. Kenneth Albrecht, died suddenly as a result of an automobile accident. This tragic ending of a talented man in his prime before he could see the results of his last labor was particularly distressing. By an especially good stroke of fortune, the services of Dr. Walter C. Alvarez, well-known gastroenterologist and writer, a member of the Mayo Clinic for the past twenty-four years and editor with distinction of *Gastroenterology* and *The American Journal of Digestive Diseases* were obtained. He has moved to Chicago and his name appears as editor in the June issue. The journal has a long list of eminent specialists on its Editorial Advisory Board and in the capacity of Managing Publisher, the able Mac F. Cahal. Dr. Stanley R. Truman of Oakland, California, is chairman of the Publication Committee as well as president of The Academy. The first articles to appear in GP are of high calibre, and the section on Practical Therapeutics is of very special value to the general practitioner. We extend our best wishes for the success of GP,* the launching of which, though beset with tragedy, has been nevertheless most auspicious.

THE AMERICAN JOURNAL OF PROCTOLOGY

The American Journal of Proctology made its debut in March of this year. It claims to be the first authoritative journal of proctology and allied subjects and is owned and published quarterly by the International Academy of Proctology, Inc., with editorial office at 43 Kissena Boulevard, Flushing, New York, and business office at 1819 Broadway, New York 23, New York. Subscription price is $2.50 per year. Members of the International Academy of Proctology receive the journal in return for the payment of membership dues.

As explained editorially in volume one of this new publication, the International Academy of Proctology was formed on June 9, 1948, to unite in one association, physicians who are interested in this specialty. The American Board of Proctology incorporated in 1935 has remained dormant ever since but was approved by the Council on Medical Specialties at a recent meeting. Thus this Board becomes the eighteenth Examining Board in the specialties. An organization meeting was held in conjunction with the American Medical Association meeting in Atlantic City in June, 1949. The Academy's first sceientific meeting also was held on this occasion and its second meeting was held at the Hotel Bellevue in San Francisco on June 23, 24, 1950.

The articles and abstracts appearing in the first number of this infant journal indicate the worthy purpose of the editors. MINNESOTA MEDICINE extends its best wishes for the growth and success of *The American Journal of Proctology.*

BE JUST BEFORE YOU ARE GENEROUS

The various communities of the State, ranging from hamlets to large cities, face a serious problem of financial drainage. It is a matter of great pride to self-respecting citizens to be able to assist in the maintenance and betterment of local charitable enterprises and institutions such as district nursing associations, the local hospitals, day nurseries or child care centers, for example, as well as various local religious institutions. Latterly, it seems to be more and more difficult to raise sufficient money to keep them going, even on a restricted basis, in spite of unremitting labor by interested citizens. What are the reasons for this difficulty?

High taxes for one thing, increased cost of living for another. Yet another is the multiplicity of organizations other than local whose appeals for aid siphon away small community resources. This is to state a fact and in no way to impugn the worthiness of these larger groups. Physicians will be interested both as citizens and doctors to know why financial support is increasingly hard to obtain for local hospitals, district nursing associations, and other aids to medical practice as well as community assets.

> A check by the National Information Bureau on national nonprofit organizations, nearly all of which solicit public aid, shows an astounding number in existence.
>
> There are, for example, no less than 75 national associations dealing with public health, ranging alphabetically from those concerned with Alcoholism through Hay Fever, Parenthood, Social Diseases, and Veterans.
>
> There are 24 national organizations dealing with the problems of Youth.
>
> There are 31 which are solicitous for continuance of "Free Enterprise" and the "American Way of Life" and the like.
>
> There are five which are anxious about the American Indian Welfare, 10 concerned with Conservation, 19 aroused over Civic Affairs, 29 which deal with International Relations, 23 interested in General Welfare, and no less than 72 seeking to help on matters connected with Foreign Relief Aid and Rehabilitation, with practically every other nation in the world on the receiving end of American charity.
>
> These are not fly-by-night organizations, mind you. Every one of the more than 400 organizations listed by the bureau is either national or international in scope.[1]

It has come to a point where drives for this and that have begun to overlap each other. It is a rare morning when the mail does not contain at least one and often two or three appeals from various sources. To the more than 400 organizations of national or international scope must be added those of less than national but not purely local character. There is, apparently, no limit.

In an expanding economy it is quite possible that all of these appeals can somehow be met, but it is to be kept in mind that the financial assistance asked is *in addition* to the steady, enormous drain through taxes to provide governmental subsidies to specially favored groups, either domestic or foreign. Matters would be much worse if any serious effort were to be made by government to reduce the national debt of some $1,700 for every man, woman, and child in the nation. It will have to be done sometime, somehow.

Meanwhile we hope that some thought will be given to a return to the time-proved maxim, "Be just before you're generous." Be sure your purely local institutions do not lack the financial assistance they merit.—Editorial N. Y. State J. Med., June 15, 1950.

MEDICAL ECONOMICS

Edited by the Committee on Medical Economics
of the
Minnesota State Medical Association
George Earl, M.D., Chairman

ENATOR McCLELLAN BLOWS AWAY THE FOG

Senator McClellan, who spoke at the second nnual Minnesota Medical Press conference in pril, recently reported to Congress on federal pending. His report is the subject of an editorial n the *Wall Street Journal,* which credits him with learing away some of the fog surrounding the overnment-stated reasons for increased federal xpenditures. The *Journal* says:

> "In recent weeks there have been repeated suggestions rom Administration officials at Washington that the reasury deficit is due to tax cuts made by the Re- ublican Congress in 1948. Also, there have been hints hat the fight against Communism accounts for rising overnment expenditures.
>
> "Now Senator McClellan of Arkansas comes along vith a report that blows away the fog that settled round the fiscal situation as a result of such suggestions. he Senator should know about such matters; he's chair- nan of the Senate Committee on Expenditures in the xecutive Department. And, of course, he's a Demo- rat, which removes any possibility that he's only having political tiff with the Administration."

Spending Increases in Four Categories

The Senator's report shows that in the coming fiscal year spending in four categories that can't possibly be related to fighting Communism, will ccount for a rise of more than $4 billion. The four categories are: social welfare, housing, farm price supports and public works. Spending for social welfare will be $845 million greater mostly due to grants to states for public assistance, public health and hospital construction. Spending for housing accounts for a $1,247 million increase. Spending for farm price supports and other aid-the-farmer efforts means an increase of $1,632 million. Spending for public works will rise $458 million due chiefly to river and harbor work.

The Journal "Heartily Agrees"

Seconding the report of Senator McClellan, and realizing where taxes go and why the government is involved so deeply in deficit spending, the Wall Street *Journal* concludes:

> "Those figures add up to $4,182 million. And that would about equal the deficit that's being incurred in the present fiscal year. When a Government is bent on spending money as fast as it can it's almost certain to find excuses for the red ink created. The tax cut of the 1948 Congress is an easy alibi; so is the anti-Communist effort. But the real truth of the fiscal situation is that spending is on the rise almost everywhere you look.
>
> "In submitting his report to the Senate, Mr. McClellan warned that 'this tremendous rising cost (of Government) is indicative of a fixed permanent trend that cannot be ignored or remain unchallenged.' And he added that this provides a 'warning of compelling force against our proceeding with reckless indifference to enact more and more laws expanding present governmental services and instigating new programs creating additional governmental obligations that will add billions annually to the already swollen costs of government.'
>
> "We heartily agree."

PURCHASING POWER NOW LESS THAN IN 1931

Due to taxes and inflationary prices, it was shown in a recent bulletin of Insurance Eoconomics Surveys, that although dollar salaries in 1950 are considerably greater than those of 1931, the purchasing power of 1950's salary is only a little more than half that of the salary of 1931.

Citing the news story of baseball player Ted Williams' recent signing with the Red Sox for a record pay of $125,000, the Survey compared his salary with that of Babe Ruth in 1931.

In a graphic presentation, the article showed that, while the salary of Babe Ruth in 1931 was only $80,000, his take-home pay amounted to more than Williams takes home today—Ruth $68,535, Williams, $62,028. This compares the two after taxes were removed. The Survey says:

> "Inflation has shrunk the buying power of the dollar since 1931, so Williams' real take-home pay is only a little over half of Ruth's—57 per cent. . . . If Ted Williams were to have as much buying power in 1950 as Babe Ruth had in 1931, he would have to be paid $327,451."

Thus, more facts help convince tax-burdened Americans that proposed government bills would increase taxes, thereby lowering take-home pay and lowering the buying power of American salaries.

DEWEY ADVISES AVOIDING NEVER-NEVER LAND

Governor Thomas E. Dewey, speaking recently at Princeton university, took a sober look at the situation causing some people to advocate adoption of compulsory government medicine, and charged that the administration is "making a strong political issue out of support of a compulsory national health bill."

"By this bill," Dewey said, "heavy additional payroll deductions or comparable taxes would be imposed on the entire population. Everyone would then get so-called 'free' medical, dental, surgical and hospital care, as in Great Britain. Mr. Truman says this is not socialized medicine. The British admit that it is. They ought to know."

Believing that not all is perfect in medicine, or in any field, Dewey declared that socialized medicine is not the way to remedy ills which are far less obvious than medical advances:

> "Of course, there are urgent problems still to be met in the field of medical care. There always will be. Many communities need hospitals. The cost of illness can often be disastrous to an individual family. Medical schools are having a tough time meeting their budgets—as who is not? In many areas we could use more doctors and dentists. But to leap from these admissions to the conclusion that socialized medicine is the only cure, is like cutting off your head because you have a headache.
>
> "Let's take a sober look at where we are before we jump into the Never-Never Land.
>
> "The simple fact is that American medicine is today the finest in history. Our entirely free medical profession and its allied scientists have conquered scourges such as diphtheria, smallpox, typhoid and scarlet fever, which once wreaked terror over whole nations. Even pneumonia is on its way out as a killer and significant progress has been made with such stubborn problems as leprosy, infantile paralysis, heart disease and cancer.
>
> "The life expectancy of Americans has been increased twenty years in just the past half century. In the last third of a century the rate of infant mortality has been cut by three-quarters. Insofar as medical personnel is concerned, we have more doctors per capita than any other great nation in the world."

Lenin An Expert on Subject

Dewey then made his to-the-point conclusion:

> "I cannot prove that compulsory medicine is the keystone of the arch of a totalitarian state, but Lenin said that it was and he was an expert on the subject."

COMMITTEE QUOTES WORDS OF WISDOM

Proving again that the wisdom of freedom is time-honored, the committee for Constitutional Government quotes the following:

> "*IT WAS WISDOM AGES AGO:* Men too often, in their revenge, set the example of doing away with those general laws to which all alike can look for salvation in adversity.—Thucydides, 426, B. C.
>
> "*IT WAS WISDOM TWO GENERATIONS AGO:* All socialism involves slavery. What is a slave? We primarily think of him as one who is owned by another. The essential question is: How much is he compelled to labor for other benefit than his own? The degree of his slavery varies according to the ratio between that which he is forced to yield up and that which he is allowed to retain; and it matters not whether his master is a single person or society. If, without option, he has to labor for society and receives from the general stock such portion as the society awards him, he becomes a slave to society. Socialistic arrangements necessitate an enslavement of this kind.—Herbert Spencer, *The Man Versus the State,* 1884.
>
> "*IT IS WISDOM TODAY:* The chief threat to human rights is no longer one of too little government. Freedom's greatest threat today is too much government, that all limits to government action may be swept away. Is there to be no line beyond which government shall not go, as it is in Soviet Russia, and becoming so in socialistic England? The plunder of our natural resources has been largely checked. Are we now to have a system of plunder of the national treasury? Is the old 'let me alone' philosophy to be replaced by nothing better than 'gimme mine' philosophy? —Bernard M. Baruch."

And, additional quotes on freedom from government interference are meaningful and relevant:

> "Today, federal taxation and government borrowing against the future are not merely . . . nuisances, they are major determinants of business policy, and they dominate and shape the course of our economic developments, the level of our prices and the extent of our national wealth. They are a lien of enormous size upon our past savings and upon our future production.—*Monthly Digest of Business Conditions.*
>
> "Freedom exists only where the people take care of the government.—Woodrow Wilson.
>
> "In a socialistic state, all men are theoretically equal financially. This country has already qualified with:
>
> Income taxes, final equalizer of all incomes.
>
> Social Security, misnomer for another tax.
>
> Federal grants, money taken from you, then you match it, and part of it comes back. . . .
>
> Estate and inheritance taxes, they get you after you're gone.—*Berea* (Ohio) *Enterprise.*"

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

Saint Paul, Minnesota

Julian F. Dubois, M.D., Secretary

UNLICENSED MASSEUSE PLEADS GUILTY TO CRIMINAL ABORTION

Re: State of Minnesota vs. Florence Fossum

On June 15, 1950, Florence Fossum, fifty-eight years of age, residing at 3133 Oakland Avenue, Minneapolis, was sentenced by the Hon. Rolf Fosseen to a term of not to exceed four years in the Women's Reformatory at Shakopee. Mrs. Fossum had pleaded guilty on May 3, 1950, to an information charging her with the crime of abortion. Judge Fosseen, following a statement by legal counsel for the Minnesota State Board of Medical Examiners and the County Attorney's office of Hennepin County, stayed the sentence for three years and placed Mrs. Fossum on probation, one of the conditions being that the defendant is to refrain from the practice of healing and specifically is forbidden to engage in the practice of massage or the operation of a health food store.

Mrs. Fossum was arrested by Minneapolis police officers on March 24, 1950, following the admission of a forty-year-old married Minneapolis woman to a Minneapolis hospital. The patient was seriously ill with an infection following a criminal abortion. Upon being questioned, the patient stated that the abortion was performed by a woman by the name of "Florence" who operated a store at 215 W. Lake Street, Minneapolis. The defendant was promptly arrested and upon being arraigned in the Municipal Court at Minneapolis, demanded a preliminary hearing which was set for April 12. However, Mrs. Fossum changed her mind, waived the preliminary hearing and entered a plea of guilty in the District Court. At the time of Mrs. Fossum's arrest Minneapolis Police Officers seized medical and surgical equipment used in the performing of abortions. Mrs. Fossum stated that she was a masseuse. However, she admitted that she holds no license to practice massage or any other form of healing in the State of Minnesota.

OPERATOR OF MEAT MARKET AND GROCERY STORE PLEADS GUILTY TO ABORTION

Re: State of Minnesota vs. Paul C. Schwede

On June 20, 1950, Paul C. Schwede, forty-five years of age, who operates a grocery store and meat market at 259 Cedar Ave., Minneapolis, was sentenced by the Hon. Rolf Fosseen, Judge of the District Court of Hennepin County, to a term of not to exceed four years in the State Prison at Stillwater for the crime of abortion. Judge Fosseen stayed the sentence for three years and placed the defendant on probation after Schwede has served three months in the Minneapolis Workhouse. Judge Fosseen also ordered Schwede's surgical instruments confiscated and turned over to the Minneapolis General Hospital.

Schwede, who holds no license to practice any form of healing in Minnesota, was arrested on May 23, 1950, following the hospitalization of a nineteen-year-old divorcee who was suffering from an infection from a criminal abortion. Minneapolis police officers found a practically new medical kit containing three speculums, a dozen catheters, surgical instruments and seven bottles of various medicinal preparations at Schwede's place of business at the time of his arrest. The investigation disclosed that the abortion was performed at the home of a former employe of Schwede's. A fee of $400 was paid for the abortion but Schwede's former employe concealed from him the fact that she withheld $250 of the fee. The accomplice was not prosecuted because she disclosed the facts leading to Schwede's arrest.

Judge Fosseen questioned Schwede carefully about his prior activities and he stated to the Court that, while he lived at 2084 Roblyn Avenue, Saint Paul, he had been in business in Minneapolis for a number of years. He admitted to the Court that he had performed a total of seven criminal abortions since the fall of 1949. When asked by Judge Fosseen as to how he learned to do abortions, he replied: "By reading medical books." Schwede said that he had been in financial difficulties and for that reason sought to supplement his income. The records of the United States District Court in Minneapolis disclose that on November 4, 1946, Schwede was fined $200 following a plea of *nolo contendere* to an information charging him with a conspiracy against the United States in connection with the illegal use of counterfeit sugar stamps.

PAN AMERICAN SANITARY BUREAU TO ASSIST VENEZUELA IN PLAGUE SURVEY

Commander Julius M. Amberson, of the U. S. Navy, Bureau of Medicine and Surgery, left Washington early in July for Venezuela to lend assistance to health authorities in making a survey of plague in that country, it was announced by the Pan American Sanitary Bureau, Regional Office of the World Health Organization. Commander Amberson is accompanied by Dr. Ernst Schwarz, also of the Bureau of Medicine and Surgery.

A small focus of plague in Venezuela has caused sporadic outbreaks of human cases over a period of years. This plague reservoir recently became active again, and the Ministry of Health requested the technical assistance of the Pan American Sanitary Bureau in making a thorough study of this problem with a view to the elimination of the center of infection.

The Bureau obtained the collaboration of Commander J. M. Amberson of the U. S. Navy. Commander Amberson has had considerable experience on field surveys of rodent and flea populations, and will make an epidemiological rodent and insect survey of the infected area. The site chosen for the study is the Campamento Rafael Rangel, 4,132 feet above sea level, and the study unit will spend from six to eight weeks in this endemic area of Venezuela.

ALL-INCLUSIVE CHEST SERVICE

The care, the study and the teaching of tuberculous disease today should be the responsibility of the broadly trained medical internist-investigator in close association with the highly proficient, experienced chest surgeon as part of the larger problem of the better understanding and control of all cardiopulmonary diseases involving the chest. Such an all-inclusive chest service should be an integral part of every large general hospital and medical teaching center, in the best interests of patients, physicians, undergraduate medical students and resident staff. This means medical center segregation in the future, rather than sanatorium isolation as in the past, with the tuberculous patient receiving equal acceptance and complete attention, including prompt recognition and specific treatment of his nontuberculous complications which ofttimes threaten his existence more seriously than does the tuberculosis, itself.—Charles A. Doan, M.D., *Ohio Public Health,* May, 1950.

Minnesota Academy of Medicine

Meeting of February 8, 1950

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, February 8, 1950. Dinner was served at 7 o'clock and the meeting was called to order at 8:10 p.m. by the President, Dr. William A. Hanson.

Minutes of the January meeting were read and approved.

The Secretary then read the annual report of the Treasurer and this was accepted.

The Executive Committee reported that it had approved the transfer to the Senior List of the names of Drs. Benjamin, Ulrich, White and Benedict.

The Executive Committee also reported that it felt the Constitution of the Academy should be studied and changes recommended; Dr. Lepak and others will go over this carefully and the recommended changes will be voted on at a future meeting.

The scientific program then followed.

RECENT ADVANCES IN THE BRONCHOSCOPIC STUDY OF PULMONARY DISEASE

ROBERT E. PRIEST, M.D.
Minneapolis, Minnesota

Rapid advances in the surgical management of intrathoracic disease have been made recently. One phase of this advance has included refinement of bronchologic methods. Accurate and simplified nomenclature to denote various parts of the lung, the use of bronchoscopic telescopes, and improvement in the collection of specimens for cytologic and histologic study have been developed. Each of these procedures entails the participation of one or more members of the thoracic surgical team.

BRONCHOSCOPIC REPORT

team; the patient is best served when the entire group is closely integrated. Several phases of bronchology will now be examined more closely.

The use of accurate simple nomenclature enables the radiologist, bronchoscopist and thoracic surgeon to discuss pulmonary conditions with great accuracy. Early bronchial anatomic classifications were confusing and complex. Boyden[1,2] and Brock[3] have published excellent

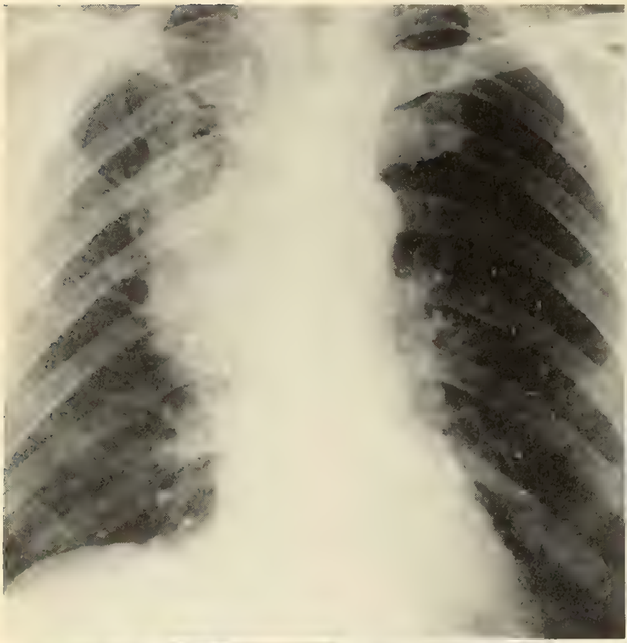

Fig. 6. (*Upper left*) Carcinoma of right upper lobe.

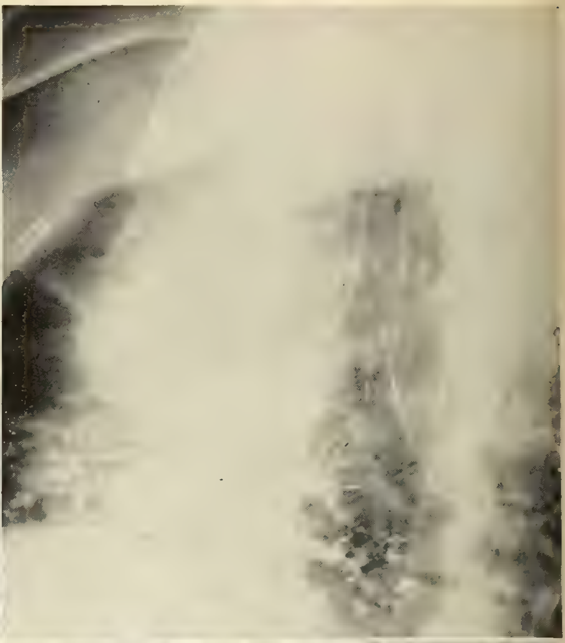

Fig. 7. (*Upper right*) Same case as Figure 6, lipiodol outlining closed upper lobe bronchus by tumor biopsied bronchoscopically.

reviews of the papers on this subject. In 1943 Jackson and Huber[8] outlined a simple descriptive classification. In 1945 Boyden[7] further simplified this system by adding numbers to the names of the main branch bronchi. Boyden's numbering system extends beyond the ten primary bronchi; he uses letters and numbers to designate arteries and veins in the same way. Overholt and Langer[9] emphasize the facility with which the surgeon can use numbers to designate certain bronchi.

Numbers are easy to use, and the classification is kept from becoming complex by numbering only those bronchi seen by the bronchoscopist either by direct vision or through the bronchoscopic telescope. A combination of the two methods with the diagram of the lung turned

upside down to coincide with the bronchoscopist's point of view is the method used here. Figure 1 illustrates the bronchial naming system. With all members of the thoracic surgical team using the same names for parts of the lung it is obvious that accuracy is greatly increased.

Complete mapping of the main branches of the bronchial tree can be done when the bronchoscopist and radi-

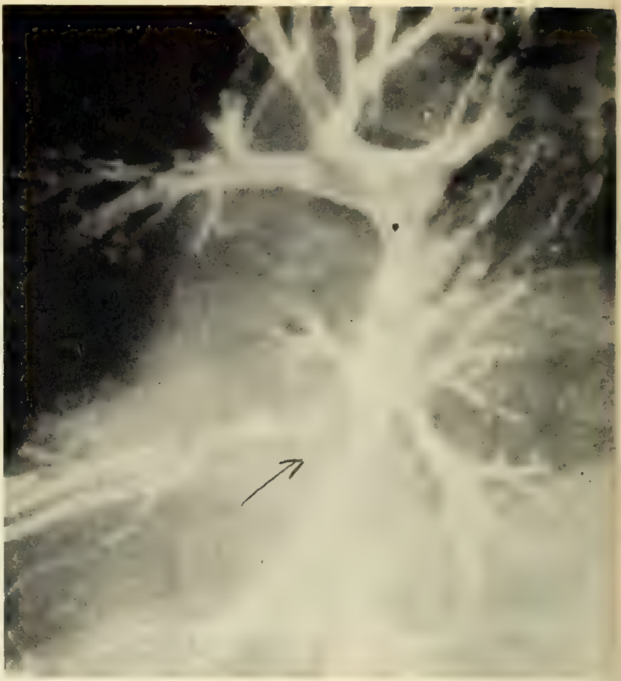

Fig. 15. Same as Figure 14 but "spot" film showing filling defect at junction of right lower and middle lobes.

Fig. 16. The right angle bronchoscopic telescope is shown. This instrument allows the bronchoscopist to look directly into the right and left upper lobe bronchi and the dorsal apical divisions of the lower lobes. The bronchi run at right angles from the main bronchi and cannot be seen through the bronchoscope alone.

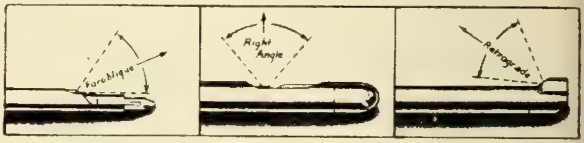

Fig. 17. Three angles of vision are possible through the right angle, forablique and retrograde telescopes.

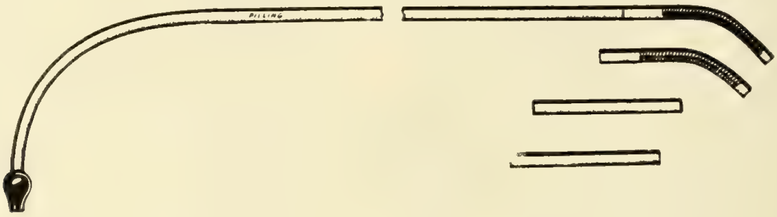

Fig. 18. Specimen collectors permitting aspiration of material into detachable suction tips where the specimens are trapped on cotton.

ologist unite their efforts. Poor and incomplete bronchograms are often seen. They do not permit accurate understanding of the extent and nature of the pulmonary disease process under consideration, and like all poor radiographs give a false sense of security to the patient. Completely adequate topical anesthesia of the bronchial mucosa, fluoroscopic visualization during instillation of the contrast medium, and the proper use of "spot" and conventially made films produce excellent maps of the pulmonary airways. (Figs. 2-15). A recent complete treatise on radiologic bronchial study is that of Di Rienzo.[5]

The use of telescopes for magnified, brilliantly illuminated visualization of the bronchial tree has been possible recently. Broyles of Johns Hopkins University developed telescopes for bronchoscopic use by modifying cystoscopic telescopes. The bronchoscopist can now make accurate visual examination of bronchi whose axes are at right angles and at various obtuse and acute angles to the main bronchi. Accurate diagnoses can be made by visualizing pathologic processes lying entirely outside the range of the ordinary tubular bronchoscope (Figs. 16 and 17).

The collection of specimens for bacteriologic and cytologic study has been improved as better aspirating devices have come into being. The collector devised by

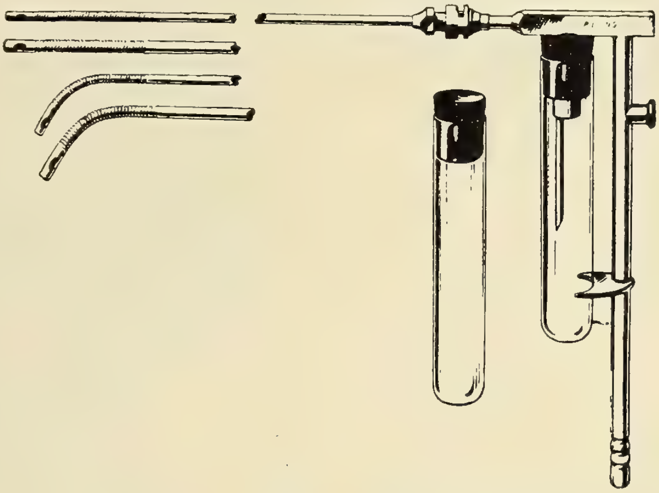

Fig. 19. Clerf aspirator in which specimen is trapped in glass tube. Detachable aspirating tips are shaped so that they may be introduced into various bronchi for aspiration from a particular segment of the lung.

erf of Jefferson University Medical School has per-
itted selective aspiration of various bronchial lobes
d segments (Figs. 18 and 19).
The cytologic study of such aspirated material has
ecome an important subspecialty in the field of pa-
ology. Bronchial washings submitted for study must
evaluated on a basis of cytology rather than micro-
opic tissue anatomy. The pathologist must be familiar
ith changes in individual cells and does not have the
portunity to base his diagnosis on abnormal tissue
chitecture. Foot[6] says, "The cytologic method has
oved to be extraordinarily reliable." He quotes Fre-
ont-Smith, Graham and Meigs[7] who said, "A negative
port does not rule out cancer. Confirmation by biopsy
almost obligatory. False positive reports can be very
nbarrassing to the cytologist." One may remark par-
thetically that the embarrassment is not limited to
e cytologist!
When all of the methods discussed here are applied
a particular patient having pulmonary disease an ac-
rate diagnosis and proper therapy are likely to result.

Discussion

Dr. L. R. Boies, Minneapolis: The excellence of this presentation makes any discussion rather superfluous. Recently, I have been re-reading "The Life of Chevalier Jackson." I recommend it to you as an inspiring account of the accomplishments of a great man. Dr. Jackson's contributions are often thought of in terms of instruments and technique, but he was more than a technician; he knew medicine. Though many have taken brief courses in endoscopic technique at his clinics he has inspired a few to follow in his footsteps. Clerf, Tucker, his son C. L. Jackson, and Holinger are his well-known pupils. The presentation by Dr. Priest tonight puts him in a class with these men.

I have always contended that it would be logical for the internist or surgeon who carries out the treatment of chest diseases to do endoscopic examinations. There has been a trend this way but it apparently has not persisted and a majority of endoscopic work is still in the hands of the laryngologist. The probable reason for this is that the laryngologist who is doing a lot of this work develops a technique and finesse which make of it a relatively simple and minor procedure, whereas the occasional endoscopist finds that for both the patient and himself there are some tribulations.

The modern resident in otolaryngology acquires a good experience in this work. In 1947, one of our residents who has now returned to Iceland reported his experiences at the University Hospital for a two-year period in which he had participated in 306 endoscopic procedures. A recent checkup at the University Hospital showed that we are now doing 25 to 30 endoscopic examinations per month. I have just had a report from our service at the U. S. Veterans Hospital which indicates that for the year ending February 1, 1950, a total of 479 endoscopic procedures were done. Approximately 90 per cent of these procedures are on the tracheobronchial tree. These figures indicate the increased demand for endoscopy and they give you some idea of the opportunity the modern resident in laryngology has to acquire skill and judgment.

Dr. T. J. Kinsella, Minneapolis: I wish to congratulate Dr. Priest upon this presentation. It is quite typical of him and the type of work that he does. Thoracic surgery requires the co-operative effort of the internist, roentgenologist, pathologist, bronchoscopist, anesthetist and thoracic surgeon for its success. Endoscopic examination is very important in arriving at a proper diagnosis. Endoscopy requires more than a mechanic if maximum information is to be obtained from the examination and the operator must know a great deal about pulmonary disease in order to interpret what he sees through the bronchoscope. We do not do our own bronchoscopic examinations because Dr. Priest furnishes us with the precise information we need in order to evaluate the patient's difficulties. Good teamwork between the various groups is what makes most of our thoracic surgery possible.

Dr. L. G. Rigler, University of Minnesota: As I watched Dr. Priest present this paper, I began to wonder whether we had a radiologist or a bronchoscopist giving this thesis. As you noted, Dr. Priest used the x-ray studies very well in demonstrating the points he wanted to make. Because x-ray examination gives such a vivid portrayal of the gross pathology it is possible to do this particularly in diseases of the chest, and I am sure Dr. Priest utilized it to its best advantage.

I would be interested in knowing if these new types of endoscopes have advanced the diagnosis of tumors of the bronchi. There is a great variation in the data as to the bronchoscopic demonstration of tumors. At one time many years ago Graham said he would never do a resection of the lung without a positive biopsy made through the bronchoscope. He said that they had had cases in which they did as many as eighteen bronchoscopies until they finally got a positive. Obviously, over this period of time it is possible that the tumor grew up to the bronchoscope. I recently heard Chevalier L. Jackson say that they were running about 72 per cent positive biopsies in cases of bronchogenic carcinoma. Most other bronchoscopists give a figure of 50 per cent or less. What I would like to know is whether there are any data to indicate that the telescopic right angle lenses have improved the percentage of positive diagnoses possible by bronchoscopy. In our experience, upper lobe carcinomas have been much more frequent than the lower lobe ones, and in those cases bronchoscopy has not been very useful in making a definitive diagnosis.

Dr. Priest, in closing: I appreciate the nice things that have been said. In answer to Dr. Rigler's question, I haven't any figures to tell you what the rise in percentage of efficiency has been. There are certain parts of the lung which can't be seen without the various telescopes. The upper lobe of both the right and left lungs are completely out of reach without telescopes unless there is deformity in the bronchus. The same is true of the apical segments of both lower lobes. You have to have a right angle telescope to see them.

In answer to the second question: there is a telescope made with which you can get a biopsy. It only passes through an adult bronchoscope so cannot be used on children. You can biopsy without the telescope if you have clear vision. The place where we could use the telescope with forceps is in very small children. You have to depend on experience and your proprioceptive sense when you apply forceps in a small child.

EXTERNAL FIXATION OF FACIAL FRACTURES

JEROME HILGER, M.D.
Saint Paul, Minnesota

A major facial injury usually results in fracture of one or more of the thirteen bones of the facial skeleton. Soft tissue laceration is frequently present. The facial derangement, however, is not a matter of first importance in a fresh injury. It is vital, first, that the airway be maintained, and second, that the patient's blood volume be restored.

A face-down, head-dependent position minimizes aspiration of blood and secretions. If the mandible is severely shattered it may be necessary to pull the tongue forward by manual or safety pin traction. Oral suction is helpful. A tracheotomy for ventilation and aspiration should be elected readily rather than denied fearfully—particularly in an unconscious patient lacking adequate reflexes.

Bleeding from major vessels provides the only justification for immediate meddling with the wound. Clamp and tie is then proper but ligatures must be left long so they can be replaced during definitive care and debridement. A sterile dressing with modest elastic pressure is proper first care in all other instances. Nasal bleeding will be no problem if left alone. Edema of the nasal mucosa quickly provides an adequate pressure hemostasis. Adequate whole blood replacement should be provided promptly.

The interval for transfusion affords an excellent period for taking stock of the patient as a whole. Extremities, thoracic cage or pelvic frame may be fractured. A high per cent of jackknifing injuries have compression fracture of vertebrae. Abdominal viscera may be ruptured. A neurological examination is essential. The middle ears should be viewed relative to basal skull fracture.

The facial derangement should properly wait on the patient's general condition. When it justifies reparative work, the whole restorative program should be already visualized. The reparative surgical procedures should be grouped. It is embarrassing to find primary bone plating of humerus or femur is indicated when the jaws have already been approximated with intermaxillary wires, and a general anesthetic is no longer possible without deranging everything so far accomplished.

Soft tissue lacerations need not be closed for forty-eight hours. Approximation with sterile tape and maintenance of modest elastic pressure is adequate emergency care. It is often distinctly advantageous to have an open wound for direct access for wire or screw fixations. It is sometimes necessary to take down an over eager or hurried primary apposition to provide access or allow more deliberate apposition under unhurried conditions.

The primary soft tissue repair is not as vital to an excellent result as is the primary skeletal repair. The facial skeleton does not lend itself well to late adjustment or secondary revision. Blood supply is excellent and periosteal surfaces plentiful. Bone union is early and firm.

SEARLE RESEARCH IN THE SERVICE OF MEDICINE

EXTERNAL FIXATION OF FACIAL FRACTURES

(Continued from Page 726)

In the primary reparative procedure reposition of displaced parts should be effected or authority over irreplaceable parts should be established. This authority must be adequate to allow application of traction to the part or of support to a part that will not maintain itself in reposition. Reposition can then be effected at will in the postoperative period. The appliances by which one can command the movement and realignment of fragments are legion. The simplest appliance that will properly align and fix is the best. Unfortunately some fractures are comminuted and complex. The screws, pins, and wires commanding individual fragments may give the superficial appearance of a Rube Goldberg creation. The component parts, however, should always represent the simplest mechanical solution to the problem.

Mandibular or lower third fragments are approximated to the maxilla or middle third. When fragments of the middle facial third are freely movable, they are supported to a plaster head cap.

Traction is used to reposition obstinate displaced fragments. It may be by elastics between maxilla and mandible, or between any fragment and head cap. Bed frame, pully, and hanging weight are occasionally necessary to disimpact fragments or correct delayed malposition.

Middle facial third fragments may take weeks and lower third fragments months to establish self-supporting bone union.

Application of various external fixation techniques are illustrated.

Discussion

Dr. C. E. Connor, Saint Paul: The fundamental principle underlying the treatment of maxillo-facial fractures is that involved in the treatment of all fractures, e.g., the best possible repositioning of fragments as soon as feasible. Two end results must be kept in mind, the cosmetic and the functional. I know of no part of the body in which the final cosmetic result is subjected to as exact scrutiny as is the face, a factor often disregarded by the family in their intense concern over the patient's chances of survival, but a consideration which the surgeon must bear in mind from the beginning of treatment, not just when the patient is well on the road to recovery and the subsidence of swelling and edema gives a preview of the final cosmetic end-result.

The functional end-result is even more important. Inadequate positioning of structures such as the mandible, maxilla, nasal bones, septum, zygomatic arch, and orbital margin can produce not only non-pleasing cosmetic results but also functional disabilities which affect the patient's health.

Plastic surgeons of wide experience in facial injuries have long endeavored to persuade automobile designers and builders to make the instrument panel a less lethal structure by the removal of protruding knobs, handles and sharp edges but have so far met with but little success.

Dr. Wallace P. Ritchie, Saint Paul: I was very fortunate to see Dr. Hilger do some of these cases. He has mentioned that they are frequently combined operations, and in several instances a combined intracranial and facial operation was carried out at the same time. One of the complications of these cases is a persistent cerebrospinal rhinorrhea. As a rule, this will stop if the bones are realigned properly, but occasionally it persists and an intracranial approach with covering of the dura tear is necessary.

Dr. Hilger, in closing: I have been fortunate in associating with Dr. Ritchie in the combined care of a number of the cases having intracranial as well as extracranial injury. Many of these cases demand combined effort. It is frequently possible and distinctly advantageous to do the intracranial repair at the time of the facial repair. In all the cases I was fortunate enough to share with him in three years of overseas service we had no death from postoperative intracranial infection. There were no repaired cases which had persistence of cerebrospinal fluid leak.

It is purposeful in closing to make special point that old thinking on severe injuries with fracture of the cribiform plate and cerebrospinal fluid leak needs revision in the light of modern antibiotic therapy. It has been customary in the past to put this type of case to bed until the cerebrospinal fluid leak ceases and then to proceed with the repair of the facial injury. Not uncommonly the facial injury in this type of case is already past the optimum time for repair by the time the cerebrospinal rhinorrhea has ceased. As one can appreciate, the thin bony floor of the anterior cranial fossa will heal by fibrous union much more promptly if the bone fragments are realigned early and placed in a near-abutting position. The marked distortion resulting from trauma oftentimes will leave a wide gap between bone fragments. This prolongs the healing period and may even result in incomplete healing and a persistent cerebrospinal fluid leak. With the use of an adequate antibiotic shield and the prior restoration of the patient's blood volume this type of combined injury should be repaired as promptly as the patient's general circumstances will permit. This actually affords earlier opportunity for healing of the anterior cranial fossa floor and thereby minimizes the opportunity for intracranial extension of infection.

I wish to thank Dr. Connor and Dr. Ritchie for their kind discussion.

The meeting adjourned.

Wallace P. Ritchie, *Secretary.*

THEY DON'T DIE YOUNG NOW

A remarkable change in the tuberculosis picture in Minnesota is evident from a comparison of the 1949 figures showing the ages at death from all forms of this disease with those of thirty years ago.

In 1919, the median (mid-point) for deaths attributed to tuberculosis was in the age group thirty to thirty-nine years. In other words, half the total deaths from this disease occurred before thirty-nine years of age. In the short period of a single generation, this situation has materially altered. Today the median for deaths from tuberculosis is in the age group fifty to fifty-nine years. Tuberculosis in a young person is still a very serious disease. But the number of young people in Minnesota who are exposed to tuberculosis has been greatly reduced during recent years, with a resulting reduction in number of deaths. Last year only forty-three persons under thirty years of age died from this disease in our state, compared with 180 deaths among persons aged sixty or over. The latter number was more than one-third of all the deaths from tuberculosis in 1949.

This change has been brought about by the tremendous reduction in the incidence of tuberculosis, particularly among young people. The reduction in deaths has been accomplished by reducing exposures to the disease through isolation of infectious cases in sanatoria; by finding and treating cases early before they become serious enough to cause death; and by the improved methods of treatment now available.—*Minnesota Health,* June, 1950.

Now Available . . . .

Complete, modern facilities of the Glenwood Hills Hospitals; co-ordinated to give an accurate diagnosis and proper treatment to the neuro-psychiatric patient.

These unique facilities include:

- **The outstanding staff of neurologists and psychiatrists in the United States**
- **The new Electroencephalograph**
- **The new Electrocardiograph**
- **An ultra-modern laboratory**
- **A completely equipped x-ray room**
- **Occupational therapy and Hydrotherapy**
- **A new physical education department**
- **Nurses specially trained in our own neuropsychiatric training school**

NOW BEGINNING—

The September class for the School of Neuro-psychiatric Nursing. Prospective candidates should apply and register immediately.

One year course—tuition free

3901 GOLDEN VALLEY ROAD MINNEAPOLIS 22, MINN.
Offering a High Standard of Facilities for 25 Years

In Memoriam

DUMA CARROLL ARNOLD

Dr. D. C. Arnold of Minneapolis died June 12, 1950, when he collapsed while walking across the campus of the University of Pennsylvania at Philadelphia.

Dr. Arnold was born January 9, 1892, in North Carolina. He received his medical degree from the University of Pennsylvania in 1920 and practiced in Roebling, New Jersey, for several years before coming to Minneapolis in 1925. Both Dr. Arnold and his wife, Dr. Ann W. Arnold, were obstetricians. They met in medical school and were married May 16, 1925. They had attended the graduation of their daughter Nancy from Vassar College shortly before, and were attending a reunion at their Alma Mater when he was stricken.

Dr. Arnold was a member of the Hennepin County Medical Society, the Minnesota State Medical Association and the American Medical Association. He was a clinical instructor in obstetrics and gynecology at the University of Minnesota.

Dr. Arnold is survived by his wife; a daughter, Nancy, and a son, Thomas B., who is a junior at Dartmouth College.

ERNEST WILLIAM COWERN

Dr. Ernest W. Cowern, a practitioner at North Saint Paul since 1903, passed away at St. John's Hospital, Saint Paul, on June 22, 1950, after a long illness.

Dr. Cowern was born in Wolverhampton, England, March 3, 1871. He obtained his medical degree from Dartmouth medical school in 1902, and after practicing for a brief time in Massachusetts and New Hampshire he came to North Saint Paul. He married Fannie Wallace Schofield of Wolfville, Nova Scotia, in 1903. She died in 1938.

Dr. Cowern served as school physician at North Saint Paul for a number of years. He was chief of staff at St. John's Hospital, Saint Paul, at one time. He was a member of Ramsey County Medical Society, the Minnesota State Medical Association and the American Medical Association. During World War I, he was medical instructor at Fort Oglethorpe, Georgia.

In 1946, Dr. Cowern was honored by a party staged in the North Saint Paul Masonic Temple. On this occasion he stated he had brought 1,360 babies into the world. Many of those at whose birth he had officiated attended the party.

Dr. Cowern is survived by three daughters: Mrs. Leslie Webster of North Saint Paul, Mrs. Donald Swift of Port Washington, New York, and Constance of Seattle. Four brothers, among them J. F. Cowern of North Saint Paul and three sisters also survive him.

EVERETT K. GEER

Dr. Everett Kinne Geer died in his home in Saint Paul on May 3, 1950, following a protracted illness.

Dr. Geer was born in Saint Paul on January 14, 1893, the son of Dr. Ethelbert F. Geer and Helen Hazen Geer. After graduating from Central High School, he attended the University of Minnesota, where he obtained a B.S. degree in 1915 and M.D. degree in 1917. He served his internship in the Minneapolis General Hospital in 1916-1917 and did postgraduate work in the Trudeau School for Tuberculosis at Saranac Lake, New York.

In the first World War, he did his tour of duty as a Lieutenant in the Medical Corps of the U. S. Navy.

In 1918, Dr. Geer married Olive Barnett Lewis. Mrs. Geer as well as a daughter, Mrs. John Donahower, and a son, Thomas, survive. His eldest son, Everett K. Geer, Jr., was killed in action in World War II.

Dr. Geer held many important positions in his special field of training. He was Chief Physician of the Tuberculosis Division at Ancker Hospital in Saint Paul from 1922 until his resignation terminated the appointment in 1949. In 1932, he was made Medical Director of the Children's Preventorium, Ramsey County, and took an active role in the management of this institution. He was consultant for Pokegama Sanatorium, Pine County, from 1920 to 1943 when the institution closed. The University of Minnesota Medical School recognized his ability by making him Instructor of Medicine in 1921 and Assistant Professor in 1934. He was a diplomate of the American Board of Internal Medicine and a fellow of the American College of Physicians.

Dr. Geer was a member of the following societies: American Heart Association, American Sanatorium Association, American Trudeau Society, Central Society for Clinical Research, International Union against Tuberculosis, Minnesota Academy of Medicine, Minnesota Society of Internal Medicine, Minnesota Pathological Society, Minnesota State Medical Association, Minnesota Trudeau Society, National Tuberculosis Association, Ramsey County Medical Society, Minnesota Public Health Association and the Ramsey County Health Association.

A number of these societies added to Dr. Geer's responsibilities by giving him official position. He was a council member of the American Trudeau Society from 1941 to 1943. In addition he served as president of the Minnesota Trudeau Society in 1934-35 and of the Ramsey County Public Health Association in 1944.

The *Index Medicus,* lists fourteen papers by Dr. Geer on problems of chest disease. In 1932, he read a paper entitled "Primary Tuberculosis Among Nurses" before the National Tuberculosis Association. This was followed by four papers on the same theme and introduced his work in the prevention of tuberculosis infection in nurses employed in institutions for the care of tuberculous patients. This contribution was outstanding, and his technique has been adopted in many sanatoria here and abroad. Dr. Geer's influence outside the United

States is illustrated by a paper in Spanish on prevention of tuberculosis infection which appeared in *El dia Medico* (Buenos Aires). He will long be remembered by those who pay attention to the prevention of tuberculosis.

WILLIAM HENTY GOUGH

Dr. William H. Gough of Granada, Minnesota, died December 7, 1949, at the Fairmont County Hospital, Fairmont, Minnesota. He was ninety years of age.

Dr. Gough was born July 24, 1859. He graduated from the Ensworth Medical College at St. Joseph, Missouri, in 1884. He was formerly a member of the Blue Earth Valley Medical Society.

JUSTUS MATTHEWS

Dr. Justus Matthews, well known specialist in the treatment of nose and throat diseases in Minneapolis, died May 21, 1950, at St. Mary's Hospital, Rochester.

Dr. Matthews was born at Foster, Minnesota, September 27, 1877. He attended the Ortonville High School. At the age of twenty-one, he joined the Minnesota Thirteenth Volunteer Regiment which fought in the Philippines during the Spanish-American war.

Starting a civil engineering course at the University of Minnesota, he switched to medicine and obtained his M.D. degree in 1905. After a year's internship at Minneapolis General hospital, he joined the Mayo Clinic staff where he headed the nose and throat section.

In 1917, Dr. Matthews came to Minneapolis where he practiced his specialty until his death. Besides being a member of the Hennepin County Medical Society, the Minnesota State Medical Association and the American Medical Association, he was a fellow of the American College of Surgeons, a member of the American Laryngological, Rhinological and Otological Society, the American Academy of Ophthalmology and Otolaryngology, the Metropolitan club of New York and the Alpha Kappa Kappa medical fraternity.

Dr. Matthews was a bachelor and lived with his sister, Harriet. He was a member of the Minneapolis Club, the Minikahda Club, the Woodhill Country Club and the Chicago Club.

JOSEPH G. PARSONS

Dr. Joseph G. Parsons, formerly an associate at the Crookston Clinic, died May 14, 1950, at Hampton Falls, New Hampshire. He retired last year and moved to Hampton Falls.

Dr. Parsons was born at Pawlet, Vermont, January 24, 1877, and attended Bowdoin College before studying medicine at the University of Minnesota, where he received his M.D. in 1898. He practiced at Sioux Falls, South Dakota, for sixteen years, at Brookings, South Dakota, for nine years, and at Lewiston, Montana, for six years before coming to Crookston in 1930.

Dr. Parsons was a member of the American Academy of Ophthalmology and Otolaryngology, a fellow of th American Association for the Advancement of Scienc and a member of the Red River Valley Medical Societ the Minnesota State Medical Association and the American Medical Association.

Dr. Parsons is survived by his wife, a son, Seth, an a daughter, Mrs. V. A. Turner of Virginia.

JOHN J. RATCLIFFE

Dr. John J. Ratcliffe, for more than forty years practitioner at Aitkin, Minnesota, died May 29, 195 at the Northern Pacific Hospital in Saint Paul. He wa seventy-eight years of age.

Dr. Ratcliffe was born April 18, 1872, at Waukon Iowa. He obtained his medical degree from Rush Medical College in 1897. He was health officer in Aitki County for many years and was a member of the Uppe Mississippi Medical Society, the Minnesota State Medical Association and the American Medical Association

Dr. Ratcliffe is survived by his wife, one son an three daughters.

SAMUEL SCHAEFER

Dr. Samuel Schaefer of Winona, Minnesota, died Ma 30, 1950, following a brief illness.

Dr. Schaefer was born at Wykoff, Minnesota, December 23, 1880. After taking a year of premedical wor at the University of North Dakota, he studied medicine at the University of Michigan, graduating in 190 Editor-in-chief of the medical school's yearbook, th young medical student won a place for himself in Ph Alpha Gamma, an honorary medical society. He interne in the hospital now known as Bellevue in New Yor City and moved to Winona in 1905.

He joined the Army at the time of the Mexica border trouble and was a captain in the medical corp in 1916 when his marriage to Ann Ahern of Winona took place at Fort Snelling. He accompanied the 131s Infantry as major in going overseas.

In 1923 Dr. Schaefer was elected alderman-at-large, an office he held for twelve years. In 1927, he was named president of the board of aldermen, an office he held for eight years. During this period, many public improvements were carried out.

Dr. Schaefer was a member of the Winona County Medical Society, the Minnesota State Medical Association and the American Medical Association. From 1936 to 1938 he was president of the staff of the Winona General Hospital.

Dr. Schaefer is survived by his wife; one son, Samuel Schaefer, Jr., a graduate student at the University of Michigan; three daughters, Dr. Jane Schaefer, an obstetrician in San Francisco, Mrs. Grayson Bryan of Santa Monica, California, and Sally Ann, at home.

JOHN P. SCHNEIDER

Dr. John P. Schneider, well-known internist of Minneapolis, died June 15, 1950, at the age of seventy-one.

Dr. Schneider was born in Lewiston, Minnesota, April

Why Should You Own Municipal Bonds?

BECAUSE— Your money is invested in a class of security that has been proved to be second only to U. S. Government bonds in certainty of payment.

It has been authoritatively reported that less than 2% of all municipal issues defaulted during the depression and nearly all of the 2% were cleared up without loss of principal.

BECAUSE— Your money earns in income that is not subject to current federal income taxes —you are not adding to your tax burden from your investment income.

Income from state and municipal bonds has never been subject to the levy of federal income taxes.

BECAUSE— Your money is securely invested and you need not be concerned with "Day-to-day market fluctuations."

Municipal bond investors buy bonds for interest income to maturity without market worries in the meantime.

★ ★ ★ ★

Here is a typical example of a municipal bond that we are currently offering to individual investors:

The Hennepin County Independent Consolidated School District No. 11, Minnesota, recently issued bonds for the construction of a new high school building because of the heavy influx of people into this suburban area. This is a recently consolidated District in Western Hennepin County that covers approximately forty square miles (over 25,000 acres) with an estimated population of 6,000. The area includes Crystal Bay, Long Lake, Maple Plain and much fine dairy and agricultural land as well as some Lake Minnetonka shore line.

The bonds are in denominations of $1,000 each and are secured by taxes levied upon all the taxable real estate and personal property within the District. As you probably realize, such taxes are a claim against the property even ahead of any mortgage. The actual value of the property is difficult to determine since, though the bulk of the population is situated in high-value residential areas (lake shore property is valued at $100 per foot in some cases) practically 90% of the area is rich agricultural land used for dairying, truck and fruit farming. The total debt, however, represents an average of only $34.60 per acre.

We own and are offering, subject to prior sale, bonds of this District returning as much as 2.35% per annum, depending upon the maturity purchased. When you are considering this investment remember that, to an individual in the $10,000 taxable income bracket, a tax-exempt 2.35% income is equivalent to more than 3.50% income subject to federal income taxes. In addition this 2.35% is exempt from present Minnesota State Income Taxes when received by an individual.

A complete descriptive circular describing these bonds will be sent you on request.

, 1879. He attended the Winona Normal School and e University of Minnesota where he received his medi- l degree in 1906. Following his internship in Minne- olis General Hospital, he practiced in Green Isle, Min- sota, for seven years. He then took postgraduate work Vienna and Berlin before establishing himself in inneapolis. He was one of the co-founders of the collet Clinic in 1920 and was an Assistant Clinical ofessor of Medicine at the University of Minnesota.

Dr. Schneider was a member of the Hennepin County edical Society, the Minnesota State Medical Associa- n and the American Medical Association, the Minne- a Society of Internal Medicine, the Minnesota Acad- y of Science, the Interurban Clinical Society, Sigma Xi, Nu Sigma Nu and the Minneapolis Athletic Club.

Dr. Schneider is survived by his wife, five daughters, Mrs. Francis Reese, Milwaukee, Wisconsin; Mrs. Jerome Speltz, Winona, Minnesota; Mrs. Alfred Speltz, Mrs. Alphonse Walch and Barbara, all of Minneapolis; and three sons, Dr. John of Philadelphia; Dr. Robert of New York, and Paul of Iowa City. He retired from active practice in 1929.

The most important factor in the development of the infant mortality rate is the standard of nutrition of the people and the most important factor in the tuberculosis rate is the standard of overcrowding.—S. Leff, Med. Officer, Feb. 4, 1950—Quoted in *Am. J. Pub. Health,* April, 1950.

✦ Reports and Announcements ✦

FOURTH PAN-AMERICAN CONGRESS ON OPHTHALMOLOGY

Plans are now under way for the Fourth Pan-American Congress on Ophthalmology to meet in Mexico City from January 6 to 12, 1952. Dr. Luis Sanchez Bulnes, Gomez Farias 19, Mexico 4, D.F., is Secretary General.

INTERNATIONAL COLLEGE OF SURGEONS

The International College of Surgeons, United States Chapter, will hold its fifteenth annual assembly and convocation in Cleveland, Ohio, October 31, November 1, 2, 3.

The program will include scientific sessions on subjects in the fields of general surgery; eye, ear, nose and throat surgery; gynecology and obstetrics; urology; and orthopedic, thoracic, plastic and neurological surgery. In addition, an extensive technical and scientific exhibit will be presented. Special entertainment for the doctors' ladies has been planned.

All doctors of medicine interested in surgery and its advancement are invited to attend, and can obtain a program upon request to Arnold S. Jackson, M.D., Secretary, Jackson Clinic, Madison 5, Wisconsin. For hotel reservations, contact Committee on Hotels, International College of Surgeons, U. S. Chapter, 511 Terminal Bldg., Cleveland 13, Ohio.

AMERICAN COLLEGE OF PHYSICIANS

On November 18, the American College of Physicians North Central Regional Meeting will be held in Madison, Wisconsin. Registration will begin at 8:00 a.m., and the meeting will consist of a series of scientific papers presented throughout the day. A scientific exhibit of wide general interest is planned in connection with the meeting.

This gathering will be held in the Wisconsin Union Theater on the campus of the University of Wisconsin. A luncheon will be served in the Wisconsin Union at noon for all registrants wishing to participate.

This postgraduate instructional session is open to all interested Physicians, whether or not they are members of the American College of Physicians. Members of the College are urged to bring along their colleagues as guests.

AMERICAN MEDICAL WRITERS' ASSOCIATION

The seventh annual meeting of the American Medical Writers' Association will be held at the Elks Club, Springfield, Illinois, Wednesday, September 27, during the fifteenth annual meeting of the Mississippi Valley Medical Society. In the afternoon there will be papers by Frank G. Dickinson, Ph.D., Director of the Bureau of Medical Economic Research, American Medical Association and Theodore R. Van Dellen, M.D., Health Editor, Chicago *Tribune*, with appropriate discussions. In the evening Walter C. Alvarez, M.D., Professor of Medicine, Mayo Foundation, Rochester, Minn., and editor of the new publication, *General Practice*, will take over, to be followed by a stag entertainment conducted by the Sagamon County Medical Society.

A program may be secured from the Secretary, Harold Swanberg, M.D., 209-224 W.C.U. Bldg., Quincy, Illinois.

MISSISSIPPI VALLEY MEDICAL SOCIETY

The fifteenth annual meeting of the Mississippi Valley Medical Society will be held at the Elks Club, Springfield, Illinois, September 27, 28, 29 under the presidency of Dr. N. G. Alcock of Iowa City, Iowa, immediate past-president of the Iowa State Medical Society. Over thirty clinical teachers from the leading medical schools will conduct this great postgraduate assembly whose entire program is planned to appeal to general practitioners. There will be over fifty scientific and technical exhibits. No registration fee will be charged and every ethical physician is cordially invited and urged to attend. The entire program and all exhibits will be held in the newly remodeled, air-conditioned Elks Club of Springfield. Program may be obtained from Harold Swanberg, M.D., Secretary, 209-224 W.C.U. Bldg., Quincy, Illinois.

COURSE IN NEUROLOGIC ROENTGENOLOGY

The University of Minnesota announces a continuation course in neurologic roentgenology to be presented at the Center for Continuation Study October 30 to November 4. Distinguished visiting physicians who will participate as faculty members of the course include Drs. Arthur E. Childe, Winnipeg; Philip J. Hodes, Philadelphia; Dabney Kerr, Iowa City; and Knut Lindblom, Stockholm, Sweden. Clinical and full-time members of the staff of the University of Minnesota and Mayo Foundation will complete the faculty for the course.

Presentations on the anatomy and pathology of the central nervous system will be given early in the course. Emphasis will be placed throughout on different techniques available for the roentgen examination of the central nervous system. Correlation of clinical and roentgenologic findings will be emphasized.

SCOTT-CARVER COUNTY SOCIETY

Election of officers highlighted the meeting of the Scott-Carver County Medical Society in New Prague on June 7.

Dr. E. H. Simons, Chaska, was elected president; Dr. Richard F. Kline, Montgomery, vice president, and Dr. E. Roger Rynda, New Prague, secretary-treasurer.

Dr. H. Nilson, Mankato, discussed the educational campaign being carried on to point out the dangers of socialized medicine.

NORTHERN MINNESOTA MEDICAL ASSOCIATION

The annual meeting of the Northern Minnesota Medical Association will be held at Bemidji on Friday and Saturday, September 8 and 9. The program for the meeting is as follows:

Friday, September 8

"Some Aspects of Abdominal Pain in Children"—Dr. Allan J. Hill, Minneapolis.

"New Developments in Antibiotics"—Dr. Wendell H. Hall, Minneapolis.

"The Significance of the Intestinal Polypoid Lesion"—Dr. Harry M. Weber, Rochester.

"The Surgical Management of Common Pulmonary Problems"—Dr. Nathan K. Jensen, Minneapolis.

"Fracture Clinic"—Dr. Daniel J. Moos, Dr. Maynard C. Nelson and Dr. Earl C. Henrikson, Minneapolis.

Banquet, 7:00 p.m. Speaker: Roy E. Dunn, Representative, 50th District.

Saturday, September 9

"Clinico-Roentgen-Pathological Conference"—Dr. E. L. Tuohy, Dr. H. G. Moehring and associates.

Officers of the association, who will be in charge at the meeting, are Dr. W. J. Deweese, Bemidji, president; Dr. George Sather, Fosston, vice president, Dr. C. L. Oppegaard, Crookston, secretary-treasurer.

Woman's Auxiliary

A MESSAGE FROM THE NEW PRESIDENT

The annual session held in Duluth, June 12 to 15, was not only very successful from the standpoint of Auxiliary work, but it was one of the most beautifully planned and conducted conventions it has been my good fortune to attend. The past State Auxiliary president and her convention chairman, together with their committee members are to be congratulated.

It is the plan of the new administration that Auxiliary work shall be carried on, as always, to promote in every way all plans supporting and furthering the national Auxiliary program. I know that all county presidents will carry back to their groups good reports of the meetings and to every county member I make a plea for help and sympathetic understanding. Again a group of outstanding and capable women are serving as Board members, but unless each county member and our members at large are sincerely interested and active, we cannot hope for a successful year. Board members can plan and advise, but it is to the individual member we must look for promotion of Auxiliary work.

Public relations is of first importance. The war against government controlled medicine and insurance must go on. More and more of our fellow citizens

must be told the truth and understand the danger to our American way of life which a small group is trying to force upon us.

We are happy that plans for two Health Days, to take place soon, are well under way. The programs which have already been given have been very successful and have been very well received. Health Days can mean so much in promoting understanding among our fellow citizens in all walks of life and certainly they are of unlimited educational value. We do hope that several more counties will promote Health Day programs during the year.

Vacation time is here, but may I ask each county president to keep on the alert, ascertaining the needs of her group and, too, the needs of her own community, as far as educational campaigns are concerned. If you have articles of interest, please send them to the Chairman of MINNESOTA MEDICINE, Mrs. Benjamin Souster, 1333 Bohland Place, Saint Paul 5, Minnesota. I do not refer to personal items, but to those which might be of help in planning programs for county work starting in the fall. Let us give unselfishly of our time and our effort to make this year one of which we can be proud and one which will be gratifying to the Minnesota State Medical Association.

President, Woman's Auxiliary

BROWN & DAY, INC.

St. Paul 1, Minnesota

✦ Of General Interest ✦

A voluntary committee composed of fellows who have served under Dr. George E. Fahr have established a **George E. Fahr Lectureship in Cardiology** at the University of Minnesota Medical School. Dr. Fahr retired from his position as full-time supervisor of the University medical service at Minneapolis General Hospital on June 15, 1950, after some twenty-eight years of service in that capacity. A dinner was held in honor of Dr. and Mrs. Fahr at the Campus Club in the Coffman Memorial Union at which the lectureship which has already reached $8,000, was presented to the Medical School. It is the purpose of the committee in charge of raising funds, of which Dr. Arthur Kerkoff is chairman, to raise a considerably larger fund to provide a suitable income for the purposes of a lectureship. Contributions made payable to the George E. Fahr Lectureship or to the Minnesota Medical Foundation, earmarked for the lectureship, may be sent to Dr. George N. Aagaard, secretary-treasurer of the Foundation, 3411 Powell Hall, University of Minnesota, Minneapolis 14, Minnesota.

* * *

Dr. Paul J. Bilka has opened offices at 500 Physicians and Surgeons Building, Minneapolis, for the practice of rheumatology. Dr. Bilka was graduated from Columbia University Medical School and served an internship and assistant residency at the Hartford Hospital, Connecticut. He was discharged from the Army as a captain in January, 1947. He recently completed a fellowship at the Mayo Clinic.

* * *

Open house was held on June 11 at the offices of **Dr. I. W. Steiner** and **Dr. W. O. Finkelnburg,** Winona, to announce completion of remodeling and refurnishing the offices. The redecorating work included increasing the number of rooms, installing new lighting and new furniture.

* * *

Dr. Vincent T. M. Ryding, Howard Lake, closed his offices late in June and left on June 27 for Dallas, Texas, to become affiliated with the Methodist Hospital of that city. He was scheduled to be replaced at Howard Lake on July 1 by Dr. William Thomas of Minneapolis, who had purchased Dr. Ryding's equipment.

* * *

After being asociated with the Bratrud Clinic in Thief River Falls since January, 1947, **Dr. Alfred S. Nelson** left on June 8 for Baltimore, Maryland, where he had accepted an appointment as resident in internal medicine at Union Memorial Hospital.

* * *

It was announced on June 8 that **Dr. Donald Bucher**, of Sioux Falls, South Dakota, planned to begin practice in Starbuck about July 15.

Dr. J. J. Coll, Duluth, was elected president of the Minnesota Society for the Study of Diseases of the Heart and Circulation at a meeting in Minneapolis on June 3 and 4.

* * *

Dr. Bernard S. Nauth, a member of the staff of the Winona Clinic for the last five years, announced on June 10 that he had resigned to enter private practice in Bemidji. He said that he planned to leave for Bemidji sometime before July 15. Dr. Nauth entered the Winona Clinic as a staff member in 1942, practiced for several months before joining the Army, then returned to Winona after his discharge from service.

* * *

Miss Olive V. Seibert, Minneapolis, director of medical publications at the Bruce Publishing Company, Saint Paul, and well known to the medical profession throughout the state, was elected president of the Quota Club International at its annual convention at Mackinac Island, Michigan, in June.

Quota Club International has 226 chapters in the United States, Canada, Australia and Mexico, and an active membership of over 7,000. Members are selected from women executives of a community, one from each business or professional activity. Quota is organized to advance the interests of women, cultivate friendship and serve country and community. Miss Seibert served Quota International as lieutenant governor, district governor, director, third vice president and first vice president before being elected president.

* * *

Dr. Julian F. DuBois, Sauk Centre, secretary of the Minnesota State Board of Medical Examiners, was elected a member of the National Board of Medical Examiners at its recent annual meeting. This is the first time a member of our state board has been honored with a membership in the national board.

* * *

The Colvin Memorial Surgical Fund, to carry on a research and teaching program at Ancker Hospital, Saint Paul, has been established in memory of Dr. Alexander R. Colvin, who died on March 22, 1948. Dr. Colvin was associated with Ancker Hospital for over fifty years and was chief of the surgical services at the hospital for more than thirty years.

Dr. Wallace P. Ritchie is director of the fund, and members of the advisory committee include Dr. E. M. Jones, chairman, Dr. Thomas E. Broadie, Dr. Ivan D. Baronofsky and Dr. Logan Leven. Contributions to the fund have so far been made by doctors who practice at Ancker but will be accepted from any who are interested in the welfare and

progress of medical teaching and research at the hospital. Contributions, which are tax deductible, should be made payable to the Colvin Memorial Surgical Fund and sent to Dr. Thomas E. Broadie, Superintendent, Ancker Hospital, Saint Paul.

* * *

Dr. R. H. Wilson has been named by the Winona city council to fill the unexpired term of the late Dr. Samuel Schafer as city health officer. Dr. Wilson's term expires in April, 1952.

* * *

Dr. Martin O. Nesheim, Emmons, was among upper Midwest physicians who attended a continuation course in proctology at the University of Minnesota May 22 through 27.

* * *

A farewell reception was given by employes of the Willmar State Hospital on June 21 in honor of **Dr. and Mrs. Stanley B. Lindley** and family. About 200 persons gathered to say farewell to Dr. Lindley, who has been superintendent of the Willmar State Hospital for the past six and one-half years. Dr. Lindley planned to leave the following week to become a chief physician at the Veterans Hospital in Knoxville, Iowa. At his new post he expects to devote most of his time to research and clinical work in psychiatry.

* * *

Dr. John Adams, who for the past ten years has been with the pediatrics department of the University of Minnesota Medical School, will spend six weeks in Europe visiting various medical centers before taking up his duties as director of the pediatrics department at the University of California Medical School in Los Angeles. Dr. Adams will read a paper on virus pneumonia at the sixth International Pediatrics congress o be held at Zurich, Switzerland in July. Mrs. Adams, who is also a pediatrician, will accompany Dr. Adams.

* * *

As part of the program being developed by **Dr. Ralph Rossen,** state mental health commissioner, his staff will be augmented by Dr. Frances Barnes, beginning July 1, who will direct pediatric care in state institutions caring for children. In addition, Dr. R. H. Engel, who has recently come to this country from Germany and who has specialized in convulsive disorders of children, has been named clinical pediatrics director at the Cambridge State School and Hospital, and Dr. H. H. Brul has been placed in charge of the pediatrics service at the Minnesota School and Colony at Faribault. The two state institutions have already been allied with the University Medical School, receiving part-time services from four senior staff members and four residents of the University Hospital.

ADVERTISED TO THE MEDICAL PROFESSION ONLY

Dr. Cole, who for more than a year has been a onsulting orthopedist at Kenny Institute, was among the medical men who originally observed the work of Sister Kenny when she first came to Minneapolis and Saint Paul in 1940.

* * *

Dr. R. F. Hedin, of the Interstate Clinic in Red Wing, was a speaker at a meeting of the St. Croix and Pierce Counties Medical Society in Ellsworth on June 13. He spoke on "Hand Infections."

* * *

Eighty physicians who interned at **St. Mary's Hospital,** Duluth, between 1901 and 1950 held a reunion breakfast in Duluth on June 13. Dr. R. P. Buckley, hospital chief-of-staff, presided at the gathering.

* * *

It was announced in June that **Dr. J. T. Boswell** would begin practice in Wanamingo early in July. Dr. Boswell recently completed his internship at the U. S. Naval Hospital at Great Lakes, Illinois.

* * *

Dr. Samuel H. Boyer, Sr., Duluth, was presented with the distinguished service award of the Minnesota State Medical Association at the association's meeting in Duluth on June 13.

A graduate of the University of Pennsylvania Medical School, Dr. Boyer first came to Duluth in 1891. During his years there he has been active both in politics and in the pioneering medical practice in the area. He is a former member of the state board of health and past president of the Minnesota State Medical Association. A son, Dr. Samuel H. Boyer, Jr., is now associated with him in practice in Duluth.

* * *

Dr. Reuben F. Erickson, mayor of Edina, filed on June 17 as a candidate for the Republican nomination for Congress in the third district. A graduate of the University of Minnesota Medical School in 1926, Dr. Erickson is president-elect of the Hennepin County Medical Society. Always interested in politics, he was a member of the 1941 session of the state legislature from the 36th district.

* * *

Dr. C. G. Nelson, Harmony, spent June and July at the University of Iowa, taking a postgraduate course in medicine. During his absence, Dr. O. M. Rotnem of Harmony conducted his practice.

* * *

Announcement was made early in June that **Dr. J. A. Guy** would begin practice in New London on July 1.

* * *

Four Mayo Clinic physicians received certificates of merit from the University of Minnesota at a ceremony in the Coffman Memorial Union on June 6. The four were Dr. John L. Crenshaw, Dr. George B. Eusterman, Dr. James C. Masson and Dr. Arthur H. Sanford.

* * *

Dr. D. E. Greene, formerly of David City, Nebraska, has become affiliated with the Starekow Clinic

1909....1950

Physiotherapy for the relief of Arthritis and related conditions. Complete physical examinations and laboratory procedures given every patient. Roy T. Pearson, M.D., Medical Director. B. F. Pearson, M.D., associate.

in Thief River Falls. A graduate of the University of Nebraska Medical School in 1943, Dr. Greene interned at the University Hospital in Omaha, then served for two years in the Army.

* * *

The marriage of **Dr. Hubert Theissen** and Miss Armoryl Keeney, both of Minneapolis, took place in Minneapolis on May 20. Dr. Theissen, a graduate of Marquette University Medical School, is affiliated with St. Mary's Hospital, Minneapolis.

* * *

Dr. F. L. Bregel, St. James, was elected president of the Redwood-Watonwan County Medical Society at a meeting in New Ulm on May 23. Other officers named were Dr. O. B. Fesenmaier, New Ulm, vice president, and Dr. Bradley Kusske, New Ulm, secretary-treasurer.

* * *

Minnesota's mental health program was discussed by **Dr. F. J. Braceland,** head of the psychiatry section at the Mayo Clinic, at a meeting of the Methodist Men's Club in Rochester on June 2.

* * *

Dr. Grant F. Hartnagel, of the Interstate Clinic in Red Wing, attended a one-week session of the International Congress on Obstetrics and Gynecology in New York late in May.

* * *

Dr. Harvey Nelson, Minneapolis, was elected president of the Minnesota Alumni Association at a meeting in Minneapolis on May 20.

* * *

Dr. F. M. MacDonald arrived in Nashwauk on May 15 to begin medical practice at the Itaska Clinic. He recently returned from Germany, where he had been with the Army of Occupation for two years.

* * *

After a year of practice in Spring Valley, **Dr. E. P. Engels** left on May 14 to take postgraduate work in medicine at the University Hospitals, Minneapolis. He was replaced at Spring Valley by Dr. W. H. Peterson, formerly of Owatonna.

* * *

Dr. Christopher Graham was again honorary chairman of the Rochester Art Festival in Rochester on May 20.

* * *

Eight persons trained in **foreign medical schools** have qualified to practice medicine in Minnesota, it was announced on May 17. Fourteen others are now taking twelve months of graduate study in clinical medicine in approved hospitals. This progress has been made since Minnesota modified its licensing regulations for displaced physicians in February, 1949. Only one applicant for license has been rejected by the state board of medical examiners.

* * *

Dr. Howard L. Horns, assistant dean of the University of Minnesota Medical School, was the principal speaker at the annual spring dinner meeting of the St. Thomas Aesculapian Club in Saint Paul on May 17.

Physicians and Hospitals Supply Co., Inc., Minneapolis, Minn.

Dr. Herbert F. Plass, Minneapolis, representing the Hennepin County Medical Society, discussed the society's attitude toward socialized medicine at a meeting of the Commonwealth Club in Minneapolis on May 19.

* * *

After twenty-one years of practice in Houston, **Dr. W. W. Canfield** left on May 14 to become a staff member of the St. Peter State Hospital.

* * *

The transformation of an eighty-two-year-old house into a modern medical office was completed in Le Sueur in June. The entire first floor of the house has been remodeled and redecorated to form a suite of medical offices for **Dr. N. N. Sonnesyn** of Le Sueur. The offices now include a reception room, examining room, x-ray room, emergency treatment room, private office and business office.

* * *

Principal speaker at a meeting of the Saint Paul Surgical Society on May 17 was **Dr. Richard L. Varco,** of the department of surgery of the University of Minnesota. Dr. Varco discussed carcinoma of the lung.

* * *

Dr. John Van Duyn, formerly of Duluth, has become surgeon for the Community Health Center and hospital in Two Harbors. He succeeds Dr. Joseph Bloom, who has moved to Duluth to conduct his practice.

Physicians named to membership in the "**Fifty Club**" at the annual meeting of the Minnesota State Medical Association in Duluth in June include the following:

Dr. Samuel Amberg, Rochester; Dr. J. B. Clement, Lester Prairie; Dr. W. H. Condit, Dr. A. E. Booth, Dr. Annah Hurd, Dr. James F. Kennedy, Dr. C. M. Oberg, Dr. J. W. Olson, Dr. S. M. White, Dr. A. E. Wilcox, all of Minneapolis; Dr. W. A. Coventry, Dr. A. T. Laird, Dr. C. W. Taylor, all of Duluth; Dr. Oscar Daignault, Benson; Dr. J. P. Freeman, Glenville; Dr. E. C. Gaines, Buffalo Lake; Dr. F. D. Gray, Marshall; Dr. A. D. Haskell, Alexandria; Dr. F. R. Huxley, Faribault; Dr. G. P. Kirk, East Grand Forks; Dr. F. M. Manson, Worthington; Dr. G. R. Matchann, Dr. F. J. Plondike, both of Saint Paul; Dr. O. W. Parker, Moose Lake; Dr. E. A. T. Reeve, Elbow Lake; Dr. T. F. Rodwell, Mahnomen; Dr. M. W. Smith, Red Wing; Dr. F. P. Strathern, St. Peter, and Dr. W. H. Valentine, Tracy.

* * *

It was announced on June 22 that **Dr. I. G. Davis,** Rushford, had sold his medical practice and would retire on July 1 because of ill health. Dr. Davis has practiced in Rushford for thirty-one years. A graduate of Rush Medical College, he interned at Lutheran Hospital, La Crosse, Wisconsin. He served in the Army during World War I.

Dr. Davis is succeeded by **Dr. Myron J. Woltjen,** who recently completed his internship at Asbury Hospital, Minneapolis. He is a graduate of the University of Minnesota Medical School.

* * *

HOSPITAL NEWS

Opening ceremonies for the new **Swift County-Benson Hospital** were held at Benson on June 18. Principal speaker at the event was Dr. Walter Kvale, consultant in the division of medicine at the Mayo Clinic. Ceremonies also included a victory dinner, a band concert and presentation of the keys for the hospital.

* * *

Fourteen staff members of **St. Barnabas Hospital**, Minneapolis, formed a special band, the "Barnabas Barn Burners," to entertain their fellows at the annual hospital picnic in early June. Costumes for the players were green surgical caps and white operating-room shirts and trousers. Audience response to their efforts was enthusiastic.

BLUE CROSS-BLUE SHIELD NEWS

The Blue Shield Board held its annual meeting in Duluth in conjunction with the Minnesota State Medical Association's annual meeting, June 12-14. All officers were re-elected. They include: Dr. Olof I. Sohlberg, Saint Paul, president; Dr. Richard R. Cranmer, Minneapolis, vice president; Dr. C. A. McKinlay, Minneapolis, secretary; and Dr. W. A. Coventry, Duluth, treasurer.

Re-elected to the board of directors for three years were Dr. Coventry; Dr. E. M. Hammes, Saint Paul; Dr. P. G. Hoeper, Mankato, and Dr. McKinlay.

Blue Shield enrollment totalled 332,288 as of April 30, and Minnesotans received over half-a-million dollars in Blue Shield benefits during the first four months of this year. By April 30, benefits to Blue Shield subscribers this year amounted to $580,645, of which $536,312 was for medical-surgical care subscribers received in hospitals, $43,383 for care received in doctors offices.

Of the total 14,422 claims submitted during this four-month period, 11,524 were incurred by subscribers in hospitals, 2,849 in doctors' offices, and 49 in homes, representing 17,860 medical-surgical services in all.

During April, Blue Shield benefits totalled $169,512 for 4,133 claims submitted, representing 5,181 Blue Shield services. Persons in the lower income group, who receive unlimited benefits under Blue Shield, presented 1,267 or 30.7 per cent of the total claims paid during April. During the first four months of this year, 4,513 unlimited subscriber claims were paid, representing 31.3 per cent of the total number of claims paid.

Participating Blue Shield doctors provided services for 3,963 or 96 per cent of the claims paid in April, and for 13,818 or 96 per cent of the claims paid during the first four months of 1950.

Over 13,000 Minnesotans enrolled in Blue Cross during April, making a total Blue Cross enrollment of 1,017,602 in Minnesota. More than a million-and-a-half persons enrolled in the 90 Blue Cross hospital service plans during the first three months of this year, making this the second highest quarterly enrollment in Blue Cross history. Over 37,444,000 persons were enrolled in Blue Cross at the end of March, representing 24 per cent of the United States population and 21 per cent of the Canadian people.

National enrollment in Blue Shield plans during the first quarter of this year has not been reported as yet.

The wise doctor has always considered his patient as a man or woman who is suffering from, say, a growth or a tuberculous infection, rather than the uninteresting container in which some morbid process happens to be placed. Norman B. Capon, M.D., F.R.C.P., *Brit. M.J.*, April 15, 1950.

BOOK REVIEWS

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical Libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

RACTICE OF MEDICINE. Fifth Edition. Jonathan Campbell Meakins, C.B.A., M.D., LL.D., D.Sc. Formerly Professor of Medicine and Director of the Department of Medicine, McGill University; formerly Physician-in-Chief, Royal Victoria Hospital, Montreal; formerly Professor of Therapeutics and Clinical Medicine, University of Edinburgh; Fellow of Royal Society of Edinburgh; Fellow of Royal Society of Canada; Fellow of the Royal College of Physicians, London; Fellow of the Royal College of Physicians, Edinburgh; Honorary Fellow of the Royal College of Surgeons, Edinburgh; Fellow of the Royal College of Physicians, Canada; Fellow of the American College of Physicians; Honorary Fellow of the Royal Society of Medicine. 1,558 pages. Illus. Price $13.50, cloth. St. Louis: C. V. Mosby Co., 1950.

HE MERCK MANUAL OF DIAGNOSIS AND THERAPY. Eighth Edition. 1,592 pages. Illus. Price $4.50, regular edition, $5.00, thumb indexed edition. Rahway, N. J.: Merck & Co., Inc., 1950.

SSENTIALS OF OPHTHALMOLOGY. Roland I. Pritikin, M.D., F.A.C.S., F.I.C.S., Eye Surgeon, Rockford Memorial, Winnebago County and Swedish-American Hospitals; Consulting Ophthalmologist, St. Anthony Hospital, Rockford, Hospital. 561 pages. Illus. Price, $7.50, cloth. Philadelphia: J. B. Lippincott Company, 1950.

AINTS, SINNERS AND PSYCHIATRY. Camilla M. Anderson, M.D. Assistant Clinical Professor of Psychiatry, University of Utah. 206 pages. Price $2.95, cloth. Philadelphia: J. B. Lippincott Company, 1950.

HE MASK OF SANITY. (Second edition). Hervey Cleckley, M.D., Professor of Psychiatry and Neurology, University of Georgia School of Medicine, Augusta, Ga. 569 pages. Price, $6.50, cloth. St. Louis: C. V. Mosby Co., 1950.

LINICAL ELECTROCARDIOGRAPHY. Francis F. Rosenbaum, M.D. Assistant Clinical Professor of Medicine, Marquette University School of Medicine; Staff, Milwaukee County Hospital; Associate Staff, Columbia Hospital; Adjunct Staff, Milwaukee Children's Hospital; Cardiac Consultant and Attendant, Cardiac Clinic, Milwaukee Children's Hospital, Milwaukee, Wisconsin; Edited by Henry A. Christian, A.M., M.D., LL.D., Sc.D. (Hon.), M.A.C.P., Hon.F.R.C.P.(Can.), D.S.CM.(A.M.A.). (Reprinted from Oxford Loose-Leaf Medicine with the same page numbers as in that work.) 200 pages. Illus. Price, $4.50, cloth. New York: Oxford University Press, 1950.

LINICAL LABORATORY METHODS AND DIAGNOSIS. By R. B. H. Gradwohl, M.D., Director of the Gradwohl School of Laboratory Technique, St. Louis, Mo. 4th Edition, 3275 pages. Price $40.00. St. Louis: C. V. Mosby Company, 1948.

This three-volume work on "Clinical Laboratory meth- ds and Diagnosis" is a fourth edition of the original ingle volume textbook of the same name on "Laboratory rocedures with their Interpretation," later enlarged to wo volumes, to which has been added in the present edi- ion, a third dealing entirely with medical parasitology.

The author is well known among laboratory workers, ot so much as a pathologist, but as a successful roprietor of a widely advertised school, established to rain people who wish to work as technical assistants and chnicians in the clinical laboratory. The first edition as published in 1935, presumably as an outgrowth of a

PRICES ON REQUEST

compendium on clinical laboratory methods, specially prepared for the use of the students in the training school and, as such, represented a compilation of techniques and procedures employed in the contemporary clinical laboratories and found in textbooks of laboratory diagnosis and clinical pathology, and in current technical journals.

Naturally, a number of methods and procedures described are obsolete or not in current use, and merely help to swell the volume, making it appear more imposing, and adding to its cost. Therefore, it is the reviewer's opinion that the first and second volumes might have been made more useful if the obsolete and discarded methods and procedures had been omitted and references thereto dropped.

Illustrations are plentiful. A majority of them are copied from other publications, and are so indicated. The original photographs and drawings are not impressive.

The present edition has been thoroughly revised, rewritten in many instances, and new materials have been added. This is particularly evident in chapters on blood chemistry, hematology, blood groups and transfusion, bacteriology, toxicologic technique, crime laboratory methods, and electrocardiography. The third volume, devoted to parasitology and tropical medicine, by Pedro Konri, Professor of Parasitology of the Faculty of Medicine, Havana University, Havana, Cuba, represents a complete treatise on medical parasitology, and probably ranks as one of the most comprehensive and best illustrated on medical parasitology. It is a pity that this volume cannot be purchased without the burden of the other two.

In size, the book is the largest ever attempted among the textbooks of clinical laboratory procedures and diagnosis, and covers the field of medical laboratory diagnosis more profusely than any in print in the English language. It may well be added as a reference in the library of a clinical laboratory, as well as in general medical libraries.

Kano Ikeda, M.D.

BRUCELLOSIS (UNDULANT FEVER): CLINICAL AND SUBCLINICAL. By Harold J. Harris, M.D., F.A.C.P., with the assistance of Blanche L. Stevenson, R.N. 544 pages. 111 illustrations—12 in color. Price $10.00. 2nd Edition, revised and enlarged. New York; Paul B. Hoeber, Inc., 1950.

This book deals with the author's experiences in 700 cases of brucellosis supplemented by other information based upon other cases in the literature. It is an enlarged and revised edition of the previous volume published in 1941. There are 544 pages and 111 illustrations, including 12 colored plates, which are interspaced in the reading matter to bring the points discussed more clearly home.

A cursory glance through the text reveals a foreword, eleven chapters, and a large bibliography which is not complete.

The foreword is written by Walter M. Simpson, M.S., M.D., F.A.C.P.

Chapter I—Introduction. Deals with the history, nomenclature, and definition of brucellosis.

Corner Penn and Plymouth Avenues North
Minneapolis Minnesota

Chapter II—Etiology. Discusses the bacteriology, morphology, serology, and other characteristics of the three known species bringing out the fact that knowledge is still far from complete as to the pathogenicity of the three species for various animals.

Chapter III—Epidemiology. Concerns itself with the infectiousness, methods of transmission, and the incidence of brucellosis in the United States and in other parts of the world.

Chapter IV—Pathology. Bears out the author's statement that because of the comparatively few deaths from brucellosis most observers have had to content themselves with operative findings, radiographic changes and clinical observations to study pathology. An attempt is made to show that the disease affects every organ in the body. The relationship of brucellosis and Hodgkin's disease is also discussed.

Chapter V—Symptomatology. In this chapter the author states that the only symptom common to all cases is fatigue. Numerous case histories of the disease with marked emphasis on the mimicry of brucellosis with so many other diseases.

Chapter VI—Diagnosis. This brings out at length the difficulties encountered in diagnosis. A positive blood culture is the only true method of diagnosis. In all patients, a suspicion of the disease should be entertained and the reliance upon cultures, agglutination reactions, skin tests, opsonocytophagic tests, and occasional biopsy of lymph gland, and their interpretation will aid in the diagnosis of latent and chronic cases. The author attaches great significance to the opsonocytophagic test as a prognostic aid in the treatment.

Chapter VII—Psychologic Studies in Chronic Brucellosis.

Chapter VIII—Prognosis points out the fact that brucellosis is not a self limited disease, and one cannot say a patient is cured because of the spontaneous remissions and exacerbations of the disease. It demonstrates the low mortality of 3.4 per cent among the cases reported and speculates over the actual morbidity of the disease.

Chapter IX—Treatment. Discusses the rôle of rest, diet, psychotherapy, diathermy, x-ray and neoarsphenamine. Results of combined sulfadiazine and streptomycin therapy, the transfusion of immune blood, of antisera, and some information on the use of newer antibiotics such as aureomycin and chloromycetin are discussed. The author spends a great deal of space on Brucella antigen therapy and places a great deal of value on its use.

Chapter X—Prophylaxis. Stresses the fact that pasteurization of milk and the removal of infected animals will do a great deal. Some speculations on immunizations in individuals are also discussed.

Chapter XI—Addenda. The newer aspects of brucellosis in relation to other diseases are described, and a more thorough discussion on aureomycin and chloromycetin, bringing it up to date, is included.

The book is a thorough, detailed treatise on brucellosis and covers the latest diagnostic methods, prognosis, prophylaxis, and treatment in concise terms. It is well written and is recommended to those who have any interest in brucellosis.

James Bellomo, M.D.

13 FLUID OZ
LACTUM
EVAPORATED
WHOLE MILK and DEXTRI MALTOSE
FORMULA FOR INFANTS
MEAD'S
MEAD JOHNSON & CO.
EVANSVILLE, IND. U.S.A.

FOR ALMOST FOUR DECADES physicians have recognized the merits of infant-feeding formulas composed of cow's milk, water and Dextri-Maltose*.

In LACTUM and DALACTUM, Mead's brings new convenience to such formulas—for LACTUM and DALACTUM are prepared for use simply by adding water.

LACTUM, a whole milk formula, is designed for full term infants with normal nutritional needs. DALACTUM is a low fat formula for both premature and full term infants with poor fat tolerance. Both are generous in protein.

UREOMYCIN

CRYSTALLINE

in Infections of the Puerperium

Aureo-
mycin

During the past year, obstetricians have become increasingly impressed with the ability of aureomycin to prevent or arrest infections of the puerperium. Where infection is feared, or has appeared, this broadly effective antibiotic is highly useful. Drug fastness and allergy are very rare following aureomycin. It is believed that this new crystalline form of aureomycin obviates nearly all side reactions.

Aureomycin has also been found effective for the control of the following infections:

Acute amebiasis, bacterial infections associated with virus influenza, bacterial and virus-like infections of the eye, bacteroides septicemia, boutonneuse fever, brucellosis, chancroid, Friedländer infections (Klebsiella pneumonia), gonorrhea (resistant), Gram-negative infections (including those caused by some of the coli-aerogenes group), Gram-positive infections (including those caused by streptococci, staphylococci, and pneumococci), granuloma inguinale, *H. influenzae* infections, lymphogranuloma venereum, peritonitis, pertussis infections (acute and subacute), primary atypical pneumonia, psittacosis (parrot fever), Q fever, rickettsialpox, Rocky Mountain spotted fever, sinusitis, subacute bacterial endocarditis resistant to penicillin, surgical infections, tick-bite fever (African), tularemia, typhus and the common infections of the uterus and adnexa.

Capsules:
Bottles of 25, 50 mg. each capsule.
Bottles of 16, 250 mg. each capsule.

Ophthalmic:
Vials of 25 mg. with dropper; solution prepared by adding 5 cc. of distilled water.

Two Instruments of hope

in petit mal

For four years, there was one high note of hope for the 100,000 or more victims of *petit mal*. This was offered by TRIDIONE, the first Abbott-developed, synthetic anticonvulsant. Its dramatic therapy restored many children, once seizure-ridden, to happy, normal lives. Soon after introduction, it was called "clearly the drug of choice in the treatment of the *petit mal* triad."[1]

But then, in 1949, PARADIONE—homologue of TRIDIONE—emerged from three years of clinical testing as an equally effective agent for the symptomatic control of *petit mal*, myoclonic jerks and akinetic seizures. Although similar in action to its predecessor, PARADIONE proved successful in many instances where lack of response or intolerance had made TRIDIONE therapy infeasible. The value of both drugs is well documented in medical journals. Please see the literature, however, before administering either TRIDIONE or PARADIONE. There are certain techniques, precautions which must be observed. Just drop us a card. All prescription pharmacies have TRIDIONE and PARADIONE in tablets, capsules, solutions. Abbott Laboratories, North Chicago, Illinois. **Abbott**

ACCEPTED COUNCIL ON PHARMACY AND CHEMISTRY AMERICAN MEDICAL ASSOCIATION

"PREMARIN"®

Estrogenic Substances (water-soluble) also known as Conjugated Estrogens (equine).

"Premarin"—a naturally conjugated estrogen—long a choice of physicians treating the climacteric—has been earning further clinical acclaim as replacement therapy in hypogenitalism.

In the treatment of hypogenitalism, "Premarin" supplies the estrogenic factors that are missing, and thus tends to eliminate the manifestation of the hypo-ovarian state. The aim of therapy is to develop the reproductive and accessory sex organs to a state compatible with normal function.

Four potencies of "Premarin" permit flexibility of dosages: 2.5 mg., 1.25 mg., 0.625 mg., and 0.3 mg. tablets; also in liquid form, 0.625 mg. in each 4 cc. (1 teaspoonful).

While sodium estrone sulfate is the principal estrogen in "Premarin," other equine estrogens...estradiol, equilin, equilenin, hippulin...are probably also present in varying amounts as water-soluble conjugates.

Supplementation

A sure step to dietary adequacy

The aim of the dietary at all times and under all conditions is to provide ample amounts—not just minimum amounts—of all nutrient essentials. Only when the daily nutrient intake is fully adequate, based on the most authoritative nutritional criteria, can the possibility of adequate nutrition be assured. It is for this reason that a food supplement assumes great importance in daily practice. It should be rich in those nutrients most likely deficient in prevailing diets or in restricted diets during illness and convalescence.

The *multiple nutrient dietary food supplement*, Ovaltine in milk, is especially suited for transforming even poor diets to full nutritional adequacy. This is clearly shown by the data in the table above.

Note in particular the high percentages of the dietary allowances for nutrients and the relatively low percentage of the total calories furnished by the servings of Ovaltine in milk. Thus, without unduly increasing the caloric intake, Ovaltine in milk greatly increases the contribution of nutrient essentials. Enticing flavor and easy digestibility are other important features of this dietary supplement.

BIRDS *are descended from reptiles*

and, like these ancestors, they do not perspire: but many a doctor is, as they say, "sweating blood" over his collections. (Or, if he isn't, his secretary is.)

Leaving ornithology and herpetology out of it and getting down to sheer economics the fact is that while we know nothing about medicine we do know ACCOUNTS RECEIVABLE. With your permission we would like to deal with your secretary—or with you if you have the time — and take off your hands all accounts more than six months past due. One hour spent plucking those accounts from your ledger now and turning them over to

PROFESSIONAL CREDIT PROTECTIVE BUREAU

for deft, tactful, conscientious, firm and effective approach and consummation of collection may save you hundreds of dollars, hours of distraction and a tremendous amount of consideration as to whether or not you are going to sacrifice any goodwill. These are days of tension. Old accounts aren't going to be any easier to gather in during the winter than now or early fall, maybe not as easy. It's time to take action.

This is a personalized, completely proved procedure. We have no black magic, no inspired touch, but what we do have is a know-how on professional debits, a background in getting in the outstanding, a technic of careful analysis of each account, a knack of taking it over as your representative in the same decent way in which you would function. The returns flow to you direct and not through us. This kind of faithful service and understanding treatment has brought in hundreds of thousands of dollars to other practitioners and we would like very much to put ourselves at your disposal and become one of the effectives of your office. Send us 35 accounts which we will handle for $35; 105 accounts for $100: we to receive 20% for all monies paid to you. AND THE ACCOUNTS CAN BE "TOUGH ONES," TOO!

Tear off the corner of this page and fill in your name and address. We will send you the required forms and a written guaranty. And be assured that we do all the work.

But . . .
Act Now!

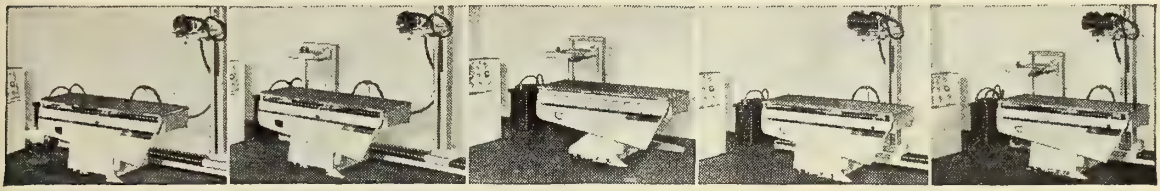
A complete range of x-ray apparatus in 10 easy steps!



THE GE MAXICON meets the medical profession's long-felt need for x-ray equipment developed to grow with an expanding practice . . . providing just the x-ray facility required . . . unit by unit as needed!

More than just a new x-ray unit, the Maxicon is a fundamentally new idea for a comprehensive line of x-ray apparatus. Specifically designed to grow with your practice Yes, the Maxicon permits you to choose only the x-ray facilities you actually want or require — from the simplest to the most complete unit. Comprised of a number of components that can be assembled in various combinations, it covers the range of diagnostic x-ray apparatus from the horizontal x-ray table to the 200-milliampere, two-tube, motor-driven combination unit.

The Maxicon series has a wealth of utility wherever diagnostic x-ray is employed. The practicing physician may select the basic unit, then let x-ray grow with his practice — by simply adding successive components from time to time. The medical specialist may arrange to have only the x-ray facilities his specialty requires.

The clinic or hospital will appreciate the application of a simple unit as auxiliary equipment in a busy department, or a complete radiographic and fluoroscopic combination to adequately meet the demands of any type of examination. Ask your GE representative for unique booklet demonstration.

A BETTER RURAL TRANSFUSION PROGRAM

A. H. BORGERSON, M.D.
Long Prairie, Minnesota

THE RURAL SURGEON visiting the larger medical and surgical centers looks with envy upon the unlimited supply of blood available to insure safety, speed convalescence and extend the range of surgical effort. He, too, needs blood to treat traumatic shock and hemorrhage, bleeding peptic ulcer, ectopic pregnancy and obstetrical blood losses, as well as for preparing his anemic patients more promptly for elective surgery. He often hopes that somehow the advantages of a blood bank may be brought to the small town hospital where he works.

The problem in closely spaced urban centers differs from that where smaller groups of people are separated by long distances or geographic barriers at times aggravated by inclement weather. The solution must be planned to fit the terrain to which it applies, and this paper will describe the program we have worked out in a typical, average small town in Minnesota.

Our village of 3,000 people, about 120 miles north of Minneapolis, serves an agricultural population of about 12,000 within a radius of 15 miles. Our twenty-three-bed hospital, soon to be replaced by a new one about twice its size, is well equipped and served by an excellent medical and nursing staff. All types of medical, obstetric and surgical emergencies are handled. The more common types of major surgery are taken care of locally, while the rare and more specialized cases of a non-urgent nature are referred to specialists in the Twin Cities or Rochester. A consulting pathologist furnishes prompt tissue diagnosis and helpful discussion of our surgical and autopsy specimens. He takes an active interest in our laboratory and administrative problems, and our blood banking plan was first suggested by him during one of our periodic conferences.

Until this year our solution of the blood problem has followed a pattern common to most small town hospitals. When the need for blood was anticipated in non-emergency cases the friends and relatives were examined, grouped and cross-matched and the blood drawn and refrigerated until needed. A "walking blood bank" was organized several years ago. The information on group, Rh, hemoglobin, physical fitness, history, serology, address and phone number of each volunteer was filed and cross indexed. From this list a donor could be obtained, the blood drawn and cross-matched within a reasonably short time to meet the need for blood in emergencies. Plasma from commercial sources and other parenteral fluids were used while waiting for the blood. Although this scheme had worked well and had saved lives in dramatic fashion, it could nevertheless be improved upon.

Accidents and emergencies occur at night, on Sunday and on holidays when the technical team trained to carry out the procedure in efficient and orderly fashion is not on duty. Delay in assembling personnel and substitution of less experienced people results in the loss of critically important time. Donors may be hard to locate and often are not properly prepared. They may have eaten recently. Serology may be too old to be reliable. The commercial plasma used to control the situation until blood becomes available is expensive and the Blue Cross does not cover

---

To be read at the third annual meeting of the American Association of Blood Banks, Chicago, Illinois, October 12-14, 1950.

its cost. Impecunious patients need blood and plasma as often as the wealthy. The lavish use of expensive materials adds to the already heavy financial burden of the hospital. Nevertheless, it is our moral obligation to meet the needs of the sick and injured without regard to their ability to pay. The soul-searching reconsideration of the case that might have been saved had plasma and blood been more readily available has its effect upon the doctor's peace of mind and perhaps on his coronary arteries as well. It was obvious to the medical group of our community that an improvement upon our old transfusion habits was urgently needed.

In addition to the high cost of commercial plasma, another obstacle to the successful operation of a small hospital blood bank is the inability to predict the need for blood in any given short period of time. On some occasions a dozen bloods might be used in a single night, while at another time no blood may be required for many days and the entire refrigerated supply wasted through too long storage.

Elements of an Ideal Rural Transfusion Program

An ideal transfusion program in a small hospital requires three provisions in addition to the ordinary procurement of blood for elective transfusion:

1. There must be available an adequate supply of plasma which the physician can use in emergency without any hesitation about the patient's ability to pay.
2. There should be a moderate supply of fresh whole blood drawn and ready for administration in emergencies as soon as the patient can be grouped and the blood matched.
3. There must be a volunteer "walking blood bank" which can be activated whenever the situation indicates that the reserve of plasma and refrigerated whole blood might be exhausted.

The community must be locally self sufficient so that this program is in effect continuously, and cannot be disrupted by storms, sleet and other conditions which might interfere with the delivery of blood from a distant point. It is true that such a program requires attention and effort on the part of the medical staff. The program is vital to them and it is only proper and wise for them to give enough of their time to supervise and retain control of this phase of their medical practice.

During a discussion of these problems our consulting pathologist, Dr. R. W. Koucky, suggested that we contact the Minneapolis War Memorial Blood Bank. In conjunction with Dr. G. A. Mattson, the director of this bank, the Long Prairie Community worked out the program which I wish to outline.

The Long Prairie Plan

With the able help of the *Long Prairie Leader* and its public spirited editor, Mr. Carl C. Carlson, a planned campaign of publicity was used to initiate the program. The community problem and the proposed solution were repeatedly emphasized. A goal, both as to numbers and as to closing date, was set. The total, to date, and the names of new volunteers were published each week. Requirements for, and contraindications to, donation were printed to minimize the number of rejected prospective donors. In a surprisingly short time, hundreds of citizens had called to give their names, addresses and telephone numbers, and to receive appointments for screening examination and donation.

Our technician, Mrs. Dorothy Robertson, spent a few days at the Minneapolis War Memorial Blood Bank, and received there instruction in the meticulous methods of screening, registration, collection, preparation, storage and shipment required to meet the exacting standards of the National Institute of Health.

Finally, the plan received its auspicious start on the appointed day in February, 1950, when fifty donors were screened, registered, and made their donations. Dr. G. A. Mattson, director of the Minneapolis War Memorial Blood Bank, came to Long Prairie for the occasion and brought with him an extra registrar and technician from his staff, both to insure that the initial effort would go off smoothly and to satisfy himself that his standards and those of the National Institute of Health were met. Fifty flasks of citrated blood were soon on their way to the Minneapolis bank in specially refrigerated hampers, and within a few days twenty-five units of irradiated plasma were on hand at the hospital.

The Long Prairie community had been offered two alternatives. We could send our blood to be converted into plasma at a fixed cost per unit, or we could receive one unit of plasma for each two units of blood sent, without any other cost. We chose the latter plan because for our community it seemed simpler and more practical. It enables us to furnish all the blood and plasma needed, to those volunteers who have established membership by blood donation, without monetary cost to them.

Since opening day, six or more bloods have been drawn each week. Our aim is to keep on hand enough blood to serve the needs of any ordinary emergency. Three or four group O bloods, together with whatever happens to come in among the less common groups, form a small reserve instantly available, and serve in other ways to exchange with and supplement the bloods drawn during that week for elective transfusion. We do not hesitate to use group O blood for emergency recipients in other groups, with the addition of the Witebsky substance, provided the donor's cells are not agglutinated in the recipient's serum.

The unused bloods, or those taken in exchange, are shipped to the Minneapolis War Memorial Blood Bank each week. Our credit there may be used to provide blood for Long Prairie patients referred to hospitals in the Twin Cities, to the Veterans Administration or University hospitals, to Rochester or Duluth, or even for Long Prairie travelers in such distant places as Seattle or Miami. This credit will also be used to provide additional plasma and such special preparations as washed cells, packed red cells or bloods of unusual group, which we may wish to order from the central blood bank.

Now, six months after its start, the local blood bank has become almost self-sustaining. Only occasionally is the community called upon to make a few more voluntary donations.

Patients who have previously donated blood to the community project are entitled to receive blood or plasma without making any replacement. Those patients who did not previously contribute, and who now receive blood or plasma from the bank, must make a replacement. They replace one unit of blood for each unit of blood received, and two units of blood for each unit of plasma received from the bank. Those who fail to make their replacement of blood must pay for it at the standard commercial rate. To make a replacement, the required number of donors are given appointments on our schedule, and as soon as the blood is collected the charge is cancelled. The blood thus received as replacement helps keep the bank solvent, and the cash paid for blood and plasma not replaced is used to defray the few incidental expenses of the bank.

Since we have had blood and plasma so readily available, we have used it so freely that we now wonder how we ever got along without our blood bank. Doctors and patients alike appreciate the convenience and safety made possible by this community project. The virtually unlimited supply of plasma, the buffer of fresh whole blood and the privilege of calling on the central bank for rare blood types, typing sera, washed red cells and consultation on our transfusion problems, has proved invaluable to us.

We are proud that this has been accomplished without help from either governmental or charitable organizations and has been done without adding to the financial burden of our hospital, our patients or our community.

It is possible that this type of program will soon be instituted in other communities within our section of the state, and that through a co-ordinated system of exchange directed through a central supervising agency, such as the Minneapolis War Memorial Blood Bank, still greater safety and convenience will be provided for the hospitals, patients and doctors of our area.

◆

HEALTH AND DISEASE

Little attention is paid to health, and it is often considered in the negative sense of absence of disease. It is challenging to current thought to point out that health and disease are not static entities but are phases of life . . . Health, in a positive sense, consists in the capacity of the organism to maintain a balance in which it may be reasonably free of undue pain, discomfort, disability, or limitation of action including social capacity.—John Romano, M.D., *J.A.M.A.*, June 3, 1950.

PSYCHOLOGICAL MEDICINE IN A GENERAL MEDICAL SETTING

RICHARD M. MAGRAW, M.D.
Minneapolis, Minnesota

ONE of the phenomena of contemporary medicine is the upsurge of psychiatry. Some doctors feel that psychiatry is, if anything, too popular, and few will doubt that the pendulum of opinion, at least with regard to some lay thinking, has swung past dead center in appraising the accomplishments and promises of psychiatry, and that time will see further shifts in this opinion.

In medical thinking, too, more time will pass before psychiatry's ultimate place as a medical specialty will have stabilized, and also before the contributions of psychiatry which are applicable to general medicine have been sorted and winnowed by experience and integrated into the general practice of medicine. In this second regard, psychiatry can be thought of not as a medical specialty, but almost as a basic science—a basic science which for want of another name might be called psychological medicine or the human approach.[20]

My subject is not what psychiatry's niche as a medical specialty may ultimately be, but is rather how psychiatry can contribute to, and psychiatric information be integrated into general medical practice.

Much of what has been said on this question is speculative, since usually those physicians who are most conversant with psychiatry have had little opportunity to apply this in the practice of medicine, and, to some extent, the converse is true.

I am going to use my experiences in the University Hospitals Medical Clinic during the past year as a basis for discussing this question. But there are obvious difficulties to drawing any very dogmatic conclusions on this basis. For one thing, a year is not a very long time. Moreover, an analysis of one's own work is apt to be rather subjective, and the fact that the factors we are analyzing are subtle doesn't make it any less so. Furthermore, while the Medical Clinic is the closest approach we have in this institution to the actual practice of medicine, it is not entirely comparable to the practice of medicine as I have known it at least. For example, the case load there is heavily weighted by special problems referred to the University, such as cataracts, malignancies, and prostatism. Then, too, we don't, as a rule, know as much about our clinic patients as the family doctor does. My findings in the Medical Clinic are therefore not precisely comparable to what might happen in practice.

While I am talking about difficulties in presenting the subject, there are two other points that ought to be made. In this day of the popularization of psychiatry, of psychoanalytically tinged comic strips and movies, and when the term psychosomatic has become a household byword, we all have had to develop ideas (one might almost say convictions) about the role of emotions in the genesis of disease and about the psychological aspects of treatment. As far as I have been able to tell, everybody has developed a different philosophy about this, and one of the difficulties in discussing the subject is that I am confronted by almost as many different points of view as there are readers of this article.

To some of us, psychiatric pronouncements in this regard seem a little fantastic and slightly improper. Others are prone to rather uncritically accept psychiatric theorizing and are in this sense "more Royalist than the King." To most of us some of the psychiatric inferences drawn from behavior touch too close to our inner feelings for us to be entirely able to view the ideas objectively.

One other thing which makes a discussion of this subject difficult is the extent of the "psychological dimension" in practice. As Menninger said, discussing "emotional factors" in medicine "is comparable to a discussion of chemical factors"[10] in medicine.

When I started working in the Medical Clinic a year ago after a little better than two years in psychiatry and neurology, I had the usual misgivings about what I had forgotten in medicine.

I wish particularly to express my indebtedness to Dr. Robert D. Mooney of Saint Paul with whom I share an interest in this aspect of medicine. He and I have discussed this subject so extensively that it is impossible for me to tell where my ideas leave off and his begin.

Acknowledgment is also made to Drs. Donald W. Hastings, Cecil J. Watson, C. Knight Aldrich, and the staff of the Medical Clinic for their support.

This article appeared in *The Bulletin of the University of Minnesota Hospitals and Minnesota Medical Foundation* for March 17, 1950.

I remember the near panic I experienced when I realized that I couldn't remember which lung had three lobes. However, I found, as others of you have with a similar experience, that what was forgotten quickly came back.

But these were not the only misgivings I had. There were in my own mind (and in the minds of the people with whom I had discussed this departure from the beaten path) questions as to just how what I had learned in psychiatry would apply in general practice. I intend to discuss my subject by restating those questions about whether what one can learn in psychiatry is applicable in medical practice and then giving the answers that have emerged in the Medical Clinic the past year. Before I do that, however, I think it would be wise to clarify a little what these things are that one can learn from psychiatry.

You are all familiar with some of the things which are learned in psychiatric training, such as the characteristics of behavior in the various psychoses, the procedures of insulin and electric shock. These things are associated with psychiatry as a specialty.

There are other skills and attitudes which psychiatry teaches for use in both its functions as a medical specialty and as a basic science, of which you are less apt to be aware.

For example, psychiatric training should bring an understanding of the limitations of psychiatry and a recognition that one's goals may have to be fairly modest. It must have been a psychiatrist who first said, "You can't make a silk purse out of a sow's ear." The student must come to recognize that bilateral far-advanced tuberculosis with cavitation of the psyche or carcinomatoses of the soul are far more frequent than their organic analogues, and he reluctantly comes to see that it is no more possible completely to remake the personality than it is to remake the body.

Furthermore, the student should get an awareness of unconscious motivations and thinking. Psychiatric training can equip the trainee with a working knowledge of this domain wherein appears to lie that majority of our thought processes of which we ourselves are completely unaware.

From this awareness of unconscious feelings comes an understanding of symbolism in thought and symptom. I am sorry I do not have more time to discuss this since it is hard to overestimate the importance of understanding unconscious feelings in understanding the "Language of Symptoms." In the few cases I am going to describe later I think the symbolic expression of unconscious feelings will be quite evident.

Another set of skills which are particularly difficult to explain, but which are especially pertinent to what we are talking about, are those which give the doctor clues as to what kind of a person the patient has been and what his present mental state is. This kind of skill has long been identified in medicine as "the Art of Medicine." All psychiatry has done here is to refine and bring up to a level of thought where we can talk about and study them, things which we have used intuitively for years.

It would be nice if the psychiatrist could carry with him a stethoscope especially designed for hearing emotional overtones. For one thing it might be easier for some of us to believe that he does hear the things he claims to. I am sure that I need not point out to you that the psychiatrists walk these halls unencumbered by such diagnostic appliances as stethoscopes, ophthalmoscopes, and without even a percussion hammer, although this is an heretical thought.

In the absence of such mechanical aids in diagnosis, the doctor must rely on his own senses to get an understanding of the patient's feelings. He must "listen with the third ear"[14] and read between the lines to catch the shades of feeling which are his clinical facts. It is well to remember that when we are dealing with another person in any face-to-face situation, there are many kinds of communication involved other than the words spoken. We can see things in a patient's posture, demeanor, and expression which speak eloquent volumes about him. Thus we learn, for example, how he feels about us and conversely, he divines whether we like him.

Lumped together in a structure called an "interview," these subtle skills compose the tools a psychiatrist carries about in his side pocket. Further, this is the equipment he uses in treatment as well as in diagnosis.

Now these points we have been considering are what we ask about when we raise questions as to how or to what extent psychiatric skills and knowledge can be incorporated into general medical practice.

One of the questions which was brought up when I was going to start in the Medical Clinic a year ago was the question of time. Would it be practicable, simply from the standpoint of time, to include in the usual medical workup more than an intuitive assessment of the patient's personality and of his background? Moreover, again from the standpoint of time, would it be possible in ordinary medical therapy to go further in the treatment of patients than just to say, "You're nervous," "It's your nerves," or "There's nothing organically wrong with you. Go home and forget it"? Experience in the Medical Clinic clearly indicates that the answer to these questions is "yes."

It has been possible to practice this kind of medicine there and to carry a full clinic load without getting bogged down in any way. In fact in the Medical Clinic it has seemed to me that diagnosing and treating patients using the comprehensive approach is actually quicker than using other approaches. So what might at first glance be thought to be the long way around, appears to be the short way through. This is what we might expect since in every phase of medicine the quickest way to complete things is to get at the core of the difficulty.

The saving of time is especially evident when we are dealing with patients with functional complaints. We have all experienced the time-consuming chase of "will-o'-the-wisp" complaints upone diagnostic by-way and down another, only to wind up with nothing to show for our efforts but strained relationships with the patient. I am not suggesting that this comprehensive approach is going to obviate the "diagnostic impasse" we reach with such complaints, but it has been my experience that it has held the key to a surprising number of such situations. I would like to cite some recent cases to emphasize these points.

Case 1.—This patient, a forty-year-old unmarried schoolteacher, came in for a checkup complaining of tightness and drawing over the left precordium with radiation to the left shoulder and down the left arm to the hand. The pain was not clearly related to exertion and had been present intermittently for about two years. During this period the patient had not been working. Physical examination was normal except that the patient was manifestly depressed.

By picking up and following out clues in the manner I described earlier the following story was brought out. The patient indicated that she had thought she might have cancer of the breast. Indeed the manner in which she said this suggested that she might welcome that diagnosis.

At the time of onset of the present complaints two years before, the patient's mother had died of breast cancer. (In explaining this the patient gestured toward her own left breast.) At that time the patient had experienced a similar feeling of tightness in her left hand and in fact her left hand had been clenched for two weeks then so that she could not voluntarily relax it, but had to pry her fingers open with her right hand.

In her second visit to the clinic this patient was able with a little help to express some of the deep anger she felt toward her mother with considerable subjective and objective improvement. She remembered that three years before her mother had died, at a time when she herself had been sick with pneumonia, she had had thoughts of violence toward her mother and a young nephew living with her mother at that time. For years she had supported her mother, had in fact purchased a home for the mother, only to see the mother devote her substance and efforts to the care of her sons, who always came first. She spoke with deep feeling of the senseless beatings she had received as a girl while her stepbrothers got off with little more than a reprimand.

The patient had been placed in an orphanage twice in her childhood for a period of about a year each time. The first time was as a very young child when her father abandoned the family and the second was at the age of twelve when her stepfather died. During the patient's hospital stay with pneumonia, she looked forward to convalescing at home under the care of her mother. As she said, she had been counting on "getting close to mother at last" only to find when she got home that the mother's interests were centered in the nephew.

She explained her unemployment in the past two years by saying that she guessed she had just become "tired of being the breadwinner for the family."

Case 2.—This patient, a thirty-two-year-old mother of three, was first seen on the same morning as Case 1. Her complaints were superficially similar to Case 1 in that she also suffered pain in the left chest, shoulder, arm, and hand. On physical examination there was tenderness in these areas most marked over the left humerus. This patient also was obviously depressed. It needed no questioning or indirection to elicit from her a concern that she might have a cancer of the breast.

Her complaints dated back eight weeks to about the time when she had decided to divorce her husband. About one year previously her husband had beaten her severely on the left side of the body as she lay in bed.

She was also seen on one other clinic visit after the initial examination. During the second visit the almost overwhelming self-doubts and self-accusations she felt over many things in her life and especially over the divorce came out. She felt that it was somehow all her fault and brought forth a good many rationalizations as to why she shouldn't go through with the divorce. I suggested that she was really being rather unrealistic in taking on all the blame for this and that apparently she didn't really have a very good opinion of herself. I suggested further that perhaps one of the reasons she found the idea of divorce so disturbing was that it only served to heighten her sense of failure and strengthen her inner convictions of her own unworthiness. Coincident with this discussion the patient's demeanor and expression changed. She became more relaxed and left saying she felt better already. The patient was seen again ten days later and to all intents and purposes was well.

Part of the concern which was felt about whether this approach would require too much time came from the assumption that psychological medicine was something that had to be done in addition to and separate from the rest of the doctor's job rather than right along with it. In Medical Clinic I learned again that a thorough medical workup of history taking and physical examination is the best routine way of establishing rapport. Similarly I learned that the opportunities for quick evaluation of personality are better in this setting than any other I know of. Consequently it has been interesting and gratifying to find that this kind of handling of emotional problems can be done almost with the back of one's hand and with an over-all saving of time to the physician. It can be done in an unobtrusive fashion wherein the patient is not entirely aware of what is happening and hence the usual resistance to psychiatric treatment does not arise.

The question of how much time it is going to take to practice medicine in this way depends in part on how deeply one goes in treating emotional problems. What I have been saying is that there is a level of psychotherapy other than that of a thorough "vacuuming and dredging of complexes"[1] which experience has thus far shown to be particularly effective in a general medical setting, and to which medical practice is peculiarly adapted.

This has a different but not necessarily inferior goal to that long-term, time-consuming, expensive type of therapy which has come to represent to some the *"sine qua non"* of psychiatric treatment. This level of psychotherapy can be compared to incision and drainage of an abscess with evacuation of the collection of emotional pus as its goal. In this treatment the physician not only drains the abscess but may help the patient avoid similar future accumulations of pus if the patient's own native powers of resistance do not appear adequate.

Oftentimes it is surprisingly easy to do this kind of psychotherapy. However, before I cite additional cases, I would like to digress a moment to emphasize that in handling emotional problems, as in other problems in medicine, we expect different patients to achieve varying therapeutic goals. One cannot expect a perfect or even satisfactory result in many cases here just as one cannot expect to restore certain cardiac cases to anything like full activity. Consequently, there is a lot of room in the handling of emotional problems for therapeutic conservatism and the light touch. It is well to avoid the error that Rogerson described as "unwise therapeutic push-fullness."[15]

I would like to use additional cases for illustration. These cases I am using are samples rather than selections or exceptions since a good portion of the patients coming to the Medical Clinic for their initial examinations present this kind of problem.

Case 3.—This patient was a middle-aged woman who in addition to slight anorexia complained of a constant right upper quadrant abdominal pain which was not related to food intake but tended to be accentuated by activity (in her case, usually housework). In response to a question as to what the pain made her think about she said that once years ago she had been kicked in that area by an adolescent daughter. The daughter had been a thorn in her side from her earliest years because of a convulsive disorder and as a behavior problem. The patient then indicated that she was waiting the daughter's return from the Cambridge Epileptic Colony where she had been treated for several years. Further it developed that on the day her abdominal pain started she had received a letter from this institution stating that her daughter was to be discharged to her home as it was felt that she could now make some sort of an adjustment outside of the institution.

Case 4.—This patient was a forty-four-year-old married woman, mother of ten children, who complained of palpitation and of numbness and stiffness of her hands and fingers. She first developed these symptoms in the summer of 1949. They came on one night when she was in bed nursing her two-months-old baby. At that time she became faint and felt as though she was losing consciousness. She suffered palpitation and her hands became numb and stiff. She described and demonstrated this to me by saying she felt she "couldn't close them together." Her husband was not living at home at the time except for weekends as he had taken a job in Minneapolis. Shortly before this episode the patient had learned of his affair with a woman in Minneapolis and had felt a burning resentment about it which she had largely been unable to express to him. While we don't really know the answer, the things I have told you and the rest of the evidence available indicated that this symptom portrayed this conscientious mother's horrified repression of vengeful thoughts about her husband and/or their youngest child.

I have pointed out that uncovering and treating the psychological factors in these cases did not require any extra part of the doctor's time in the Medical Clinic. I think it is important to explain that this conserving of time in the Medical Clinic was not done at the expense of added work for the specialty clinics or for the laboratory. In fact, I think the opposite was true. It has been my impression that using a comprehensive approach in the Medical Clinic resulted in considerable economy in laboratory and x-ray procedures and in hospitalization.

I do not mean to imply that such economies are the reason for applying psychological medicine, for I think the improvement in medical care inherent in its use is obvious. However, I do feel that such economies are an inevitable result and a welcome result, too, in this day when the rising cost of care is one of medicine's major problems.

Similarly, the use of this approach seemed to necessitate fewer of the "rule out disease" variety of referrals to the specialty clinics. I felt that fewer patients needed to be started off on the clinic merry-go-round in the hope that they would come back labeled. Fewer, too, wound up as "floaters," drifting vaguely through the clinics. Those who have worked in any of the out-patient specialty clinics know what a burdensome and frustrating load this kind of patient makes.

Some of you may be wondering whether I didn't find it necessary to get what might be regarded as unnecessary consultations and laboratory tests anyway in order to establish rapport and convince the patient. I have become convinced that while it is sometimes necessary to use these stratagems in this way, in general, they do not work as well as we like to think they do. Perhaps this is a good time to point out that when we order a plethora of laboratory and x-ray procedures ostensibly to convince the patient, more often than not we are ordering these procedures to bolster our own confidence in our diagnoses. When we have facts such as are apparent in the case histories given, we need less of such reassurance. With regard to using a profusion of laboratory tests to impress the patient with the thoroughness of the examination and thus establish rapport, I can only say that there are easier ways of establishing better rapport inherent in psychological medicine.

This brings us to a consideration of the second question that came up in regard to integrating psychological medicine into medical practice. That question was asked in various ways. "Is this factual?" "How accurate are these guesses about patients' feelings?" "How much can we rely on our impressions of emotional aspects of cases in proceeding in treatment?" "Is this information exact enough so that we can really bank on it and be safe in not pushing our diagnostic armamentarium to the utmost?"

The answer that I have found is that these facts can be used with the same confidence that we use any other facts gathered in our medical workup. However, just as the radiologist can see facts on a film that the uninitiated have not learned to see, so skills such as we described earlier enable one to gather from a patient psychological facts which may not be evident to someone less sensitive in this regard. Because of our almost exclusively materialistic background, it is easier for doctors to see the radiologist's "facts" derived from the film than to see psychological facts derived from equally good evidence. It is hard for us to make confident use of clinical information obtained through skills in interpersonal dealing. We have all seen carefully correct medical workups which omit nearly all of the really relevant information for this reason. Thus we might see duly recorded in a history of a patient with gynecological complaints, for example, the fact that the patient had measles at age four but find no mention of the fact that living her early years with a brutal, indifferent father had colored all her subsequent feelings about and reactions to sex.

The question here, then, is not so much "Is this material factual?" as it is "How can we doctors overcome our own blind spots and mental sets so as to be able to accept this material as factual and act on it?" It seems to me that a doctor's ability to recognize and integrate these facts into medical practice is a measure of his working understanding of the total organism point of view that we all pay lip service to these days.

Given a set of facts such as in the case of the woman whose daughter had kicked her long ago, the question is no longer whether we are justified in not working to the limit our diagnostic instruments, our special departments, and the patient in an attempt to pin something organic on the patient, but rather whether we are justified in doing so.

There is still a third question. "Does becoming interested in psychological medicine make one more likely to miss organic disease?" I think it is evident that an exaggerated development or interest in this regard might have the same effect as a distorted interest in any special part of medicine, including the usual extra interest in organic disorders with which medical training has endowed most of us.

As I have indicated earlier, an awareness of emotional factors does not exclude an awareness of organic factors. There is no more excuse for slighting organic factors while paying attention to emotional factors than for neglecting to examine the patient's heart irrespective of the demonstration of pathology during examination of his lungs.

I think the question has been well answered by Weiss in the quotation, "Somebody usually reminds me that in becoming interested in psychosomatic medicine one may overlook organic disease, not mentioning that an exclusive organic orientation leads to equally serious consequences in overlooking neurotic illness. Of course, as long as we are human, we are going to make mistakes. But if we plant one foot firmly in tissue pathology and the other foot firmly in psychopathology, then I think we have the correct balance for this approach."[17]

These are the main questions which came up before I started on the Medical Clinic regarding the feasibility of integrating psychiatry into medical practice, and these, too, are the observations I made in the Medical Clinic in answer to them.

While in the Clinic I have learned some other things about this kind of practice which I would like to talk about briefly before I conclude.

I was surprised to learn how frequently depressions occurred as the primary difficulty in patients consulting a doctor in a general medical practice. At first I thought this might be peculiar to the University Hospitals, but I learned that other doctors in practice have had the same experience. It was interesting to see how few of these patients expressed depression in psychological terms. Almost all were disguised by physical complaints. Out of the last 150 new patients I saw in the Medical Clinic prior to January 1, 1950, depression was the sole or major problem in eighteen. It was impressive to observe that among the patients seen, persons who developed symptoms of peptic ulcer for the first time during middle age were all in a depression at the time they had their symptoms.

One very pleasant thing I discovered about this kind of practice was that the practice of medicine was more satisfying than it had ever been before. You all know how we tend to get the major part of our pleasure in medicine out of making a difficult organic diagnosis and competing in the diagnostic game, the kind of satisfaction that makes us push hard and stretch points to diagnose a rare condition such as Cushing's Syndrome, et cetera. Obviously this attitude is hard on the neurotic. Whitehorn called attention to this fact when he said that "the neurotic runs the considerable risk of being reacted against emotionally as if he or she were cheating in the diagnostic game." I no longer feel that neurotic complaints are merely unavoidable chaff to be waded through to get at the organic nuggets mixed in. It seems to me now that almost every case has the potentialities of enthusiastic interest which I used to reserve for diagnosing multiple myeloma ectopic pregnancy, and the like. Incidentally, I think this new frame of mind makes it easier to treat the kind of problems that make up the bulk of practice since an ability to feel friendly interest in the patient is the cornerstone of therapy.

I am a little afraid that what I have been saying might leave you with the impression that psychological medicine is something to be applied only in dealing with functional complaints. Actually, it is a universally useful instrument in our relationships with all patients.

THE 1949 CANCER STATISTICAL STUDY

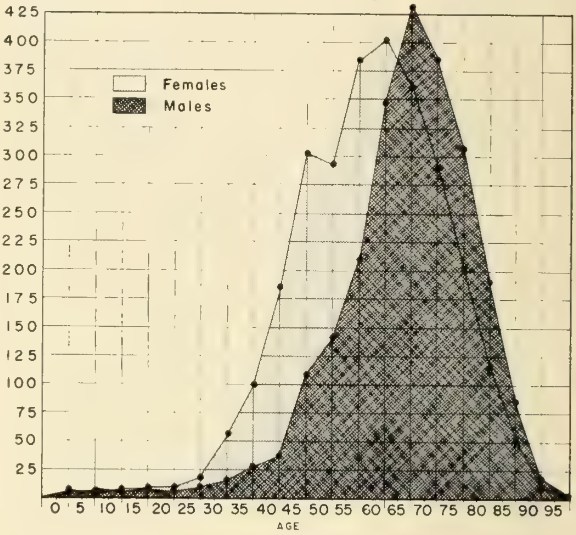
Minnesota Department of Health

N. O. PEARCE, M.D.
Acting Director, Division of Heart Disease and Cancer Control
and
D. S. FLEMING, M.D., M.P.H.
Chief, Section of Preventible Diseases
Minneapolis, Minnesota

IN 1948, the Division of Cancer Control of the Minnesota Department of Health began a statistical study of reported cases of cancer among patients in hospitals throughout the state. Findings accumulated during the initial year of the study were published in the January, 1950, issue of MINNESOTA MEDICINE.[2] That preliminary study was based on 3,798 case reports collected under a State Board of Health regulation. In order to assure legal protection for those participating in the study, cancer reporting was inaugurated into a statute by the 1949 State Legislature. The total cases reported during 1948 were 5,176. The number of cases included in the present (1949) report, total 5,473, an increase of 297 over the 1948 total. The rate at which cases are being reported for the first six months of 1950 would indicate a further substantial increase by the time the 1950 study is terminated as of April 15, 1951.

The number of hospitals reporting has also increased. During 1949, thirty-five additional hospitals came into the program, making a total of 178 hospitals reporting cancer cases as of December 31, 1949. This total is 90 per cent of the hospitals in Minnesota requested to participate. In respect to percentage of hospitals reporting, Minnesota compares very favorably with other states in which there is a program of statistical reporting on cancer. This fact is brought out in a recent study by the Cancer Control Division of the Pennsylvania Department of Health.[1]. In that study, letters and questionnaires were sent to fifty-three state and territorial departments of health to find out what methods were used and what measure of success was achieved in different sections of the country. Of the forty-four states replying, nineteen favored voluntary reporting by hospitals. Among states that depend upon this system, the percentage of hospitals cooperating is not impressive. Pennsylvania compares favorably with other states, with only 30 per cent of Pennsylvania hospitals reporting.

CANCER AMONG MINNESOTA RESIDENTS
Reported during 1949



The method used in Minnesota is voluntary reporting by hospitals. Two field workers are employed to visit hospitals and aid recorders in making their reports on cancer cases as complete as possible. Excellent cooperation has been given by practically all hospitals. The chief problem encountered in any voluntary reporting system is the difficulty in obtaining complete histories on patients hospitalized with cancer. The two most important questions asked are these:

> How long after noticing his symptoms did the patient delay before seeing his doctor?
>
> How long after the first visit to the first physician was the patient hospitalized?

Answers to these questions depend upon histories contained in hospital medical records. These histories in turn depend upon the memories of both the doctor and the patient, which cannot always be relied upon. It is hoped that, during 1950, more accurate reports can be obtained through more intensive field work.

Despite an increase in number of reports—162 more among males in 1949 than in 1948, and 135

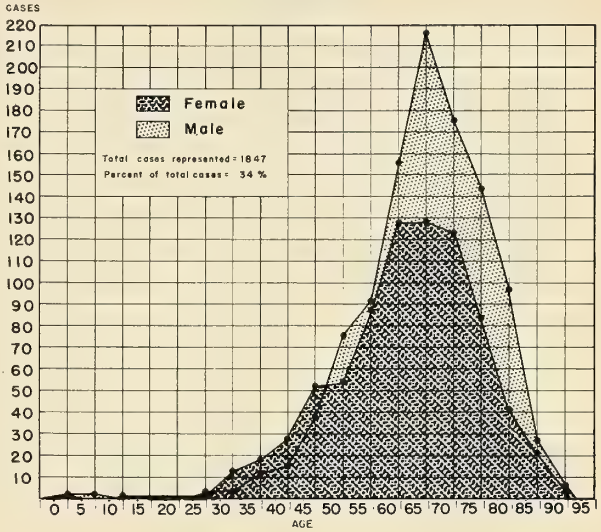
DIGESTIVE CANCER AMONG RESIDENTS OF MINNESOTA
Reported during 1949



more among females—morbidity percentages for cancers in both male and female patients are altered very little, whether one considers the over-all picture or those representing cancers at specific sites. Peak year and age-range pictures are also similar for 1948 and 1949. Table 1 compares the number of cancer cases reported in 1948 with the corresponding figures for 1949, by patients' counties of residence.

The cancer cases reported as discharged by Minnesota hospitals during the period from January 1 to December 31, 1949—a total of 5,473 cases—are used as the basis for the graphs presented in this report. Regarding sites of cancer, as shown in the graphs, the following situations may be noteworthy:

Cancer of the digestive tract, with a total of 1847 cases, including esophagus, bowel, rectum and other sites in the digestive organs, comprises the largest single group of reported neoplasms in the Minnesota study. In digestive tract cancer, cases among males are more frequent than among females, the peak year for both sexes being sixty-seven and the age range from forty-two to eighty-seven years.

In cancer of the breast, most of the cases are found between the ages of forty-two and seventy-two years, as in the 1948 picture. Cancer of the male breast is negligible.

According to the study, cancer of the uterus, including the cervix, occurs mostly between the

ages of thirty-two and eighty-two years, and is much more prevalent than cancers of the other female genital organs.

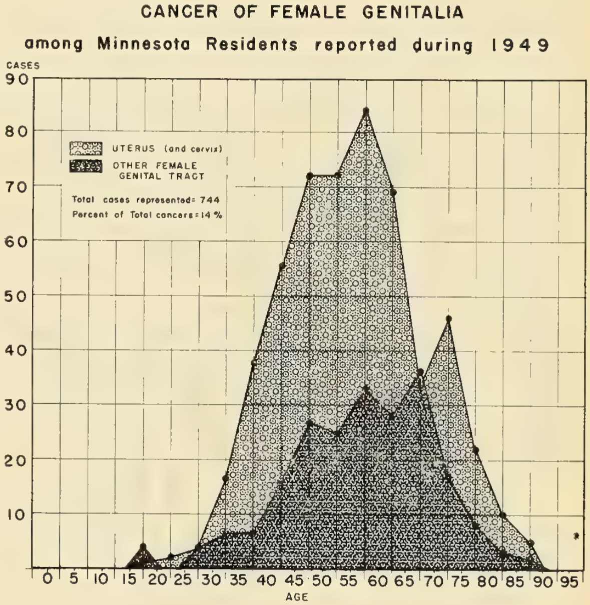
From the reports, cancer of the prostate hardly ever occurs before the age of fifty-two years, with the bulk of the cases appearing between fifty-seven and ninety-two. Cancer of other male genitalia is insignificant.

A few cases of urinary tract cancer were reported as early as the age of two years. Both males and females begin to show urinary cancers in greater numbers at the age of thirty-seven years and continue to age ninety-two; more cases are found among males.

The 297 cases of respiratory tract cancer reported make up 5 per cent of the total. This type of cancer appears nearly three times as often in the male as in the female. The age range is from forty-two years to eighty-two years for both sexes.

Buccal cancer is more prevalent in our reports among males than females. While both groups reach a peak at age sixty-two, cases range from thirty-two to eighty-seven years of age. No buccal cancer is recorded before the age of twenty-seven.

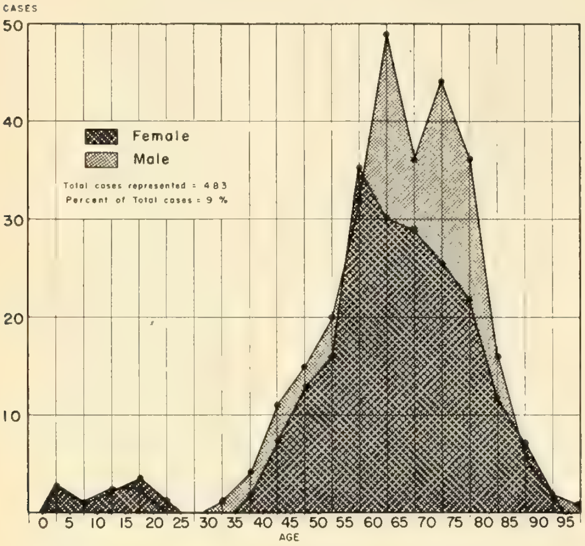
With only eighty-eight cases of skin cancer reported, no consistent pattern is found. Cancers of the skin occur as early as seventeen years and manifest themselves in greater numbers toward the latter part of life. This holds true for both male and female, with cases predominating among males.



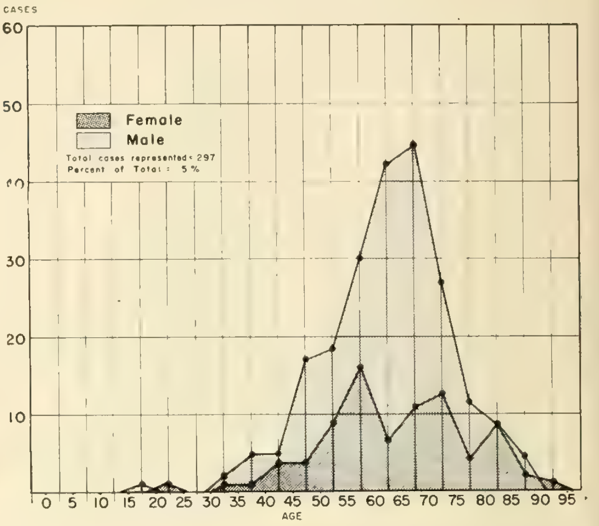
Reports show that the majority of cases of cancer of the brain and central nervous system occur earlier in life than most other true cancers. The female age range continues a little later in life than the male.

Leukemia is chiefly a disease of the very young; 60 per cent of the cases reported are under fifteen years of age. Most of the leukemias in later life are found in the age groups forty-two to eighty-two.

Although reported cases range from age seven to eighty-seven, no real pattern of occurrence can be demonstrated for Hodgkin's disease. However,



URINARY CANCER AMONG RESIDENTS OF MINNESOTA
Reported during 1949



RESPIRATORY CANCER AMONG RESIDENTS OF MINNESOTA
Reported during 1949

this conclusion is based on only eighty-one cases, or 2 per cent of the total.

In 1949, as in 1948, it was demonstrated that patients with cancer of the mouth and skin are the last to seek medical advice, while leukemia, Hodgkin's, and cancer of the central nervous system are the types of malignancy that send patients to their physicians earliest.

Over half of the patients with cancer of the digestive tract, female genital organs, breast, respiratory tract, and male genital organs (other than prostate) representing 68 per cent of the total cases reported, were hospitalized in less than a week after first seeing a physician.

Comparison was made, by site, of the Minneapolis, Saint Paul, and Duluth cases with the total picture. No significant difference was observed.

Summary and Conclusions

1. A statistical analysis of 5,473 cancer cases reported as discharged by Minnesota hospitals during the period January 1 to December 31, 1949, is presented. This represents an increase of 297 cases over the 1948 total of 5,176.

2. The current (1949) report represents voluntary participation by 90 per cent of Minnesota's hospitals. In the reporting of cancer cases, Minnesota ranks very high among states using a voluntary hospital reporting system.

3. Despite an increase in number of cases reported in 1949 over 1948, incidence of cancer, by site, among Minnesota hospital patients was virtually the same in 1949 as in 1948.

4. More accurate reporting is desirable regarding duration of delay by patients in reporting symptoms to physicians and by physicians in hospitalizing patients.

5. Much more intensive education of the public is desirable regarding the recognition of symptoms of cancers of the mouth and skin, which offer the best prognosis yet are usually the latest to be reported to physicians.

The final diagnosis in pulmonary tuberculosis rests upon the demonstration of the tubercle bacillus just as that of carcinoma of the lungs depends upon histologic proof. A reasonable certainty of predicted diagnosis can be obtained in about four-fifths of the cases with only the usual x-ray examination such as posteroanterior, oblique or lateral films.—MERRILL C. SOSMAN, M.D., New England J. Med., June 1, 1950.

Today, because of procedures which have become routine, the private physician's office is a bulwark against such diseases as smallpox and diphtheria. In like manner, it can become one of the most effective agencies for tuberculosis control. By promoting such a public health measure, the general practitioners of the nation would be acting in line with the great tradition of the profession as a force for prevention as well as cure of disease. —A. C. CHRISTIE, M.D., *Pub. Health Rep.,* June 2, 1950.

INFANT METHEMOGLOBINEMIA IN MINNESOTA DUE TO NITRATES IN WELL WATER

A. B. ROSENFIELD, M.D., M.P.H., and ROBERTA HUSTON, B.Ch.E.

Minneapolis, Minnesota

IT should be emphasized at the outset that this is not primarily a clinical study. Comparatively few infants were examined and none was treated by the State Health Department. The data were furnished by the attending physicians but many physicians were visited to obtain more complete information. Most of the field work, however, was devoted to the engineering aspects of the water supplies. This was basically a study of a public health problem. The study was inaugurated to determine whether methemoglobinemia due to nitrates in well water had occurred in the past, whether it was still occurring, its frequency and its distribution. In addition, information was desired as to the characteristic signs and symptoms, the diagnosis and the treatment, particularly the preventive treatment. This information was made available to all physicians so that they might more readily recognize this disease and more adequately treat it. Toward this end the services of a pediatric consultant were made available as well as certain laboratory procedures not readily available in the rural areas. This study was a joint undertaking by the Division of Maternal and Child Health interested in the infants, and by the Section of Environmental Sanitation concerned with the toxic chemical in the water, its concentration, its variations, its distribution, and in methods of reducing or eliminating the chemical (nitrate) from the water. The subject will therefore be discussed from these two aspects.

It has been known for some time that the ingestion or absorption of various drugs such as sulfonamides, nitrobenzene compounds, acetanilid, bismuth subnitrate, sulphates, nitrates, and chlorates is capable of producing a cellular type of methemoglobinemia.[1] This is the acquired type, in contrast to congenital idiopathic methemoglobinemia, of which fifteen proved cases have been reported.[6] When no toxic agent could be detected in the acquired type, it was usually spoken of as idiopathic cyanosis.

In 1940, Schwartz and Rector[24] reported a case of methemoglobinemia of unknown origin in a two weeks' old infant living in Montana, fed on diluted evaporated milk formula, which was successfully treated with methylene blue solution. The physical examination was negative except for abnormal color of the skin. The blood contained 57 per cent methemoglobin, but the water used in the formula was not examined for nitrates. This may have been, however, a case of nitrate poisoning from well water, as such cases have since been reported in Montana.

In 1945, Comly[5] discovered the etiologic factor in two Iowa infants about one month of age who probably would have been considered as cases of idiopathic cyanosis. Interestingly enough, the father of the first infant pointed out the answer by suggesting the possibility of a peculiar reaction between the well water and the soy bean preparation used in the formula, producing a poison which caused the infant's condition. An open-mindedness on the part of the admitting physician to what appeared to be a "cock and bull" theory led to analysis of the well water. This showed a high nitrate content and thus the etiologic factor was discovered.

Following Comly's report of two proved cases and seven suspected cases from rural Iowa, Faucett and Miller[8] reported three cases in Kansas, and Ferrant[9] reported two cases from Belgium. Since then, cases have been reported from rural Manitoba,[15,16] Ontario,[15] and Saskatchewan,[22] Illinois,[29,30] Iowa,[2,11] Nebraska,[23,27] Michigan,[18,21] Kansas[10] and several other states. New York State reported its first two cases in July, 1949.[20] The condition, therefore, is apparently quite widespread in certain rural parts of the United States and Canada.

Medical Aspects

The first case of methemoglobinemia in Minnesota was reported in January, 1947, by a physician at Tyler, in southern Minnesota. Since then,

---

Aided in part by a grant from the United States Children's Bureau.

Dr. Rosenfield is director of the Division of Maternal and Child Health, Minnesota Department of Health.

Miss Huston is assistant public health engineer, Minnesota Department of Health.

Presented at University of Minnesota General Staff Meeting, March 10, 1950 and published in *Bulletin of the University of Minnesota Hospitals and Minnesota Medical Foundation*, March 10, 1950.

a total of 146 cases, including fourteen deaths, have been voluntarily reported to the Minnesota Department of Health, since methemoglobinemia is not a reportable disease.

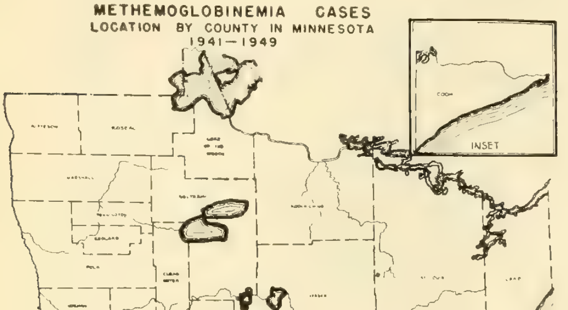

Fig. 1. Location by county of methemoglobinemia cases in Minnesota, 1941-1949.

As physicians in Minnesota became more familiar with this condition, methemoglobinemia was considered more often in differential diagnosis as evidenced by requests for methemoglobin determinations in cyanotic infants as well as frequent requests for analysis of suspected farm wells. Doubtless, many mild cases which cleared up promptly were never reported. Familiarity with this condition by physicians as well as rural parents has apparently been responsible for a markedly decreasing incidence of reported cases in 1949, only twelve cases out of a three-year total of 129 cases in 1947, 1948, and 1949. The last case was reported in July, 1949.

Distribution of Cases.—Before discussing the findings, it might be well to point out the distribution of cases in this series. As can be seen from the spot map of Minnesota (Fig. 1) practically all of the cases have occurred in the southern half of the state and most of them in southwestern Minnesota. There have been only three cases north of the midline of the state, with Detroit Lakes, in Becker County, the most northerly reported case. No cases have been reported in the northern section of the state.

Seasonal Incidence.—The incidence of cases of methemoglobinemia varied from month to month. In 139 cases out of our 146 reported cases with reliable date of onset, the highest incidence occurred in June with nineteen cases, October with eighteen and April with sixteen cases; the lowest number occurred in November with six cases. The seven cases omitted above were seen by physicians between 1941 and 1946 before our study began, which accounts for the lack of data.

Of the 129 cases that occurred in 1947, 1948, and 1949, almost one-third occurred in the second quarter—April, May and June—(31.8 per cent). The balance of the cases were more or less equally distributed in the other three quarters. The actual percentage of births in Minnesota during the same quarters were 25.0, 24.6, 26.3 and 24.1 respectively. There was a marked increase in the percentage of cases in the second quarter in comparison with the percentage of births in the same quarter. Any significance is, however, questionable because of the small number of reported cases, totaling forty-one, in comparison with the births which totalled 54,415.

It should be stated that it has not been possible to demonstrate any significant seasonal variations in the concentration of nitrate nitrogen in farm or municipal wells by periodic samplings carried out on a number of water supplies. This will be discussed in more detail under water supply aspects.

Sex.—There were eighty males and sixty-six females in the study.

Age.—As to age at onset of symptoms, over half occurred between two and four weeks of age; almost three fourths occurred between two and six weeks of age; over 90 per cent occurred under two months; and only 8.3 per cent were between two and five months of age. The youngest case was seven days old and the oldest was five months old.

Feeding.—There were twenty-one infants who were breast fed for a variable period of from one to four weeks before being changed to a formula containing well water. These infants, therefore, developed symptoms at an age from one to four weeks later than the non-breast fed infants.

The number of days the infant was on well water before symptoms developed was dependent on a number of factors, such as the nitrate nitrogen content of water, the amount of water in formula, amount and frequency of feeding, supplemental water feeding, length of time water was boiled, various physiologic considerations, and probably other unknown factors.

More than half of the 114 infants on whom this information is available (sixty-one cases) developed symptoms in one to three weeks after being on a formula requiring considerable water as a diluent. Eighteen per cent of these infants were on well water more than thirty days, the longest period being sixty days; about 15 per cent developed symptoms in less than seven days. The shortest period before symptoms developed was one day, in a two-month-old infant, on an evaporated milk formula diluted with water containing 140 parts per million of nitrate nitrogen. In this case the water was boiled for over thirty minutes to make sure all the "bugs" were killed. As a result, the nitrates were concentrated almost threefold by evaporation of water. This was demonstrated in the laboratory by boiling a sample of water from this particular well for thirty minutes. Before boiling, the nitrate nitrogen content was 140 parts per million; after thirty minutes boiling it was 410 parts per million as a result of evaporation.

Symptoms.—The characteristic symptom is a grayish blue or brownish blue cyanosis which begins around the lips, spreads to the fingers and toes, the face, and eventually covers the entire body. This occurred in all cases. When well developed, it is quite obvious. In early or mild cases the mother may not notice the cyanosis until her attention is called to it by a relative or neighbor. Incidentally, farmers who have become familiar with this condition call these infants "blue water babies." In several cases a physician making a routine periodic physical examination first noted the cyanosis.

The formulas used are of special interest. Evaporated and powered milk, which require large amounts of water as diluent, were used in 75 per cent of 116 cases with this information available. Diluted cow's milk was used in 25 per cent. No cases occurred among infants in this group who were breast fed, with only one possible exception. This was a three weeks' old infant who was breast fed, but during the four days preceding the onset of cyanosis was given, in addition, a formula of liquid SMA diluted with 1 to 1½ ounces of well water on only three occasions, plus 1½ ounces of water daily. On examination, in addition to the cyanosis there was a loud systolic murmur over the entire chest, diagnosed as congenital heart disease, from which he died some time later. Methemoglobin totaled 1.57 grams per 100 ml. of blood which constituted 11.5 per cent of the hemoglobin, and the well water contained 196 parts per million of nitrate nitrogen. It is difficult to understand how methemoglobinemia could be present with such a small quantity of formula and water and in view of the pathology present. In spite of this one possible exception, this would appear to be another reason for urging breast feeding during the first two months of life, especially in rural areas, as Medovy has suggested.[15]

TABLE I. INFANT FORMULAS IN 116 CASES OF METHEMOGLOBINEMIA

Type of Milk in Formula	Cases No.	Cases Per Cent
Evaporated	46	39.7
Powdered	41	35.3
Cows's	29	25.0
Breast fed	0	0

*Balance of 146 cases did not report formula used.

Differential Diagnosis.—In the differential diagnosis certain serious conditions must be ruled out. Among them are congenital heart disease, abnormalities of the respiratory tract such as pneumonia, atelectasis, pneumothorax, diaphragmatic hernia and congenital pulmonary and tracheal malformations, as well as "thymic syndrome." It should be remembered, as Ferrant[9] has pointed out, that there is a striking difference between the cyanosis and the alarming condition of the patient on the one hand and the normal pulse and respiration and lack of physical findings on the other. If the cyanosis is severe and persistent, systemic effects are producted due to anoxemia, and death may occur.[1,31]

Diagnosis of Methemoglobinemia.—The diagnosis of methemoglobinemia may be presumptive or absolute. In either case, however, it must first be suspected. A presumptive diagnosis may be made, if on removal of venous blood for a hemoglobin determination the blood is chocolate colored, and if there are more than 10 to 20 parts per million of nitrate nitrogen in the water used in the formula. If the blood is not examined, a presumptive diagnosis is justified if there is a spontaneous disappearance of cyanosis in twenty-four to forty-eight hours on changing the water in the formula, and the nitrate nitrogen content of the water used exceeds the suggested maximum of 10 to 20 parts per million. In either case the history and physical finding should be typical. An absolute diagnosis is made by demonstrating a definite methemoglobin line on spectroscopic examination[1] or by the chemical analytic method of Evelyn and Malloy.[7]

*By method of Evelyn and Malloy.
†Water was boiled for over 30 minutes.

In the above eight cases the diagnosis was confirmed by methemoglobin determinations by the method of Evelyn and Malloy,[7] using an electric colorimeter which was transported to the bedside of the patient on long distance telephone request to the State Health Department from the attending physician. Facilities for methemoglobin determination were not available in the rural areas where cases occurred. The readings varied from a low of 0.35 grams per 100 ml. of blood two days after hospitalization, to a high of 4.95 grams per 100 ml. of blood.

Treatment.—Treatment in most cases consisted of changing the water used in the formula to an approved municipal supply, with prompt recovery. In forty-six infants oxygen was used, but most of the physicians did not think it was of any benefit. Furthermore, removal of the infant to a hospital automatically changes the water supply and is probably responsible for the recovery in twenty-four to forty-eight hours. In severe cases more active treatment becomes necessary. One per cent methylene blue solution, 1 to 2 mg. per kg. intravenously, may be life saving.[36] It was used in nine cases with prompt recovery, the cyanosis clearing up in less than half an hour.

Mortality.—There were fourteen deaths, a mortality rate of 9.6 per cent. No specific treatment was used in these cases since the condition was either not recognized or methylene blue solution was not readily available. It is of interest to note that four deaths were ascribed to thymic hypertrophy or syndrome, notwithstanding the fact that the symptoms were characteristic of methemoglobinemia, and the well water used in the infant's formula contained 70, 120, 150, and 200 parts per million of nitrate nitrogen, respectively. There were no autopsies done on these four infants. In Minnesota during 1947 and 1948, fifteen infant deaths were reported as due to hypertrophy of the thymus, of which the four mentioned above were actually deaths from methemoglobinemia. Many cases of cyanosis in early infancy in rural areas have probably been incorrectly treated for hypertrophy of the thymus in the past. Donahoe[5] reported five cases of cyanosis in babies on farm well water who had been given from two to eight x-ray treatments for suspected thymus enlargement, but which were cases of nitrate cyanosis. Two of the thymic deaths in this series received x-ray treatment. Several infants who recovered also received x-ray treatments. Dr. G. B. Logan, Section of Pediatrics at the Mayo Clinic, states,[13] "I do not believe that an enlarged thymus is a cause of death unless it can be shown by autopsy examination."

Typical Case Histories

Case 1.—Female infant, born October 1, 1948, and discharged from hospital October 6, 1948. The formula consisted of SMA and well water, equal parts, a total of 24 ounces daily and 4 to 5 ounces of supplemental water between feedings. At age of twenty-four days, vomiting occurred; on twenty-fifth day of life, cyanosis developed. The following day a physician made a diagnosis of congenital heart disease. Five days later the infant was hospitalized at a nearby clinic where a diagnosis of methemoglobinemia due to nitrates was made. Changing the water in the formula to an approved municipal supply resulted in recovery in two days. Blood examination showed the presence of methemoglobin to the extent of 2.5 grams/200 ml. of blood. Analysis of the well water showed nitrate nitrogen 73 ppm., sulphates 70 ppm. and chlorides 28 ppm. The formula was changed to 24 ounces pasteurized milk, 8 ounces water from municipal supply and Karo. There was no recurrence.

Case 2.—A female infant was discharged from the hospital to the farm home on an evaporated milk mixture. At the age of ten days vomiting developed and persisted for several days. At the age of twenty days a generalized grayish-blue cyanosis developed. On the twenty-second day of life the infant was hospitalized when fluoroscopic examination of the chest resulted in a diagnosis of hypertrophic thymus. Oxygen was given as well as x-ray treatments daily for three days. Symptoms cleared up and the infant was discharged. Three days later, while on the same formula containing well water, cyanosis became marked and the infant was hospitalized again. The physical examination of the heart, lungs, and thymus was negative and the cyanosis cleared up in three days without any treatment, other than the change of the water. Analysis of the water from a shallow farm well showed nitrate nitrogen 90 ppm., nitrite nitrogen 4 ppm., sulphates 100 ppm. and chlorides 140 ppm. The water used in the formula was changed and there was no recurrence.

Case 3.—Female infant, born August 10, 1947, weight 7 pounds, discharged from hospital August 16, 1947, on a Lactogen formula, 16 ounces daily. On twenty-second day of life, infant developed diarrhea. On the twenty-ninth day the infant was seen by a physician who found cyanosis of the face and chest, made worse on crying. Admitted to hospital with diagnosis of "infection of the stomach." Infant was discharged on fifth day when symptoms had cleared up. On return to the farm home the same well water was used and four days later diarrhea and cyanosis returned. The physician changed the water to a municipal supply with recovery and no further recurrence. The farm well water contained nitrate nitrogen 37 ppm., sulphates 14 ppm., and chlorides 33 ppm.

Case 4.—Male infant, born August 29, 1948, discharged September 3, 1948. The infant was breast-fed but on September 10, three days before symptoms appeared, the mother added a formula consisting of cow's milk 12 ounces and water 4 ounces. In addition, 8 ounces of supplemental water were given daily. On September 13 at the age of two weeks the infant developed fussiness, excessive crying, and cyanosis of lips during crying spells. Heart, lungs and thymus negative, temperature 96°. Diagnosis was methemoglobinemia. Treatment consisted of oxygen, with recovery in twenty-four hours. Hemoglobin 69 per cent, white cells 11,000, methemoglobin 4.95 grams/100 ml. Well water contained nitrate nitrogen 500 ppm., sulphates 980 ppm., chlorides 480 ppm.

Case 5.—Female infant, born November 1, 1948, birth weight 7 pounds 1½ ounces, discharged on seventh day. The formula consisted of Biolac 1 ounce and 1½ ounces of water, 4 ounces per feeding, five times daily, plus 10 ounces of supplemental water. The water was boiled five minutes. At the age of seven weeks diarrhea and fussiness developed. The mother then diluted the formula with additional well water. Three days later a grayish-blue cyanosis began around the lips and hands and became generalized, accompanied by listlessness. The following day the infant was sent to the hospital. The physical examination was negative except for a duskiness of the skin. A diagnosis was made of methemoglobinemia. On the physician's request a methemoglobin determination was made at the bedside that evening which showed 0.97 grams/100 ml. of blood and 10 grams of hemoglobin per 100 ml. of blood. Twelve hours later (the following morning) the methemoglobin had dropped to 0.49 grams/100 ml. with clearing of the cyanosis. The mother was advised to use water from a neighboring municipal supply. The well water previously used contained nitrate nitrogen 100 ppm., sulphates 1200 ppm. and chlorides 210 ppm. Five minutes of boiling increased the nitrate nitrogen content to 166.25 ppm. No recurrence of symptoms.

Case 6.—Female infant born June 3, 1947, weight 7 pounds 15 ounces, discharged from hospital June 12, 1947, on formula of Carnation milk 14 ounces, water 21 ounces, and dextromaltose 7 tablespoons, with 5 ounces of supplemental water, boiled for ten minutes. At routine physical check-up at age of three weeks a physician noted cyanosis. City water was substituted with recovery in twenty-four hours and no recurrence. Analysis of farm well water showed nitrate nitrogen 62 ppm., sulphates 360 ppm., and chlorides 84 ppm.

Discussion

The question as to why only young infants, usually under two months of age, and not older members of the family develop cyanosis is difficult to answer. Incidentally, not all young infants develop this condition. There have been a number of instances in this series where one infant developed cyanosis, whereas a sibling, born one or two years previously, fed on a simliar formula and using water from the same well, failed to develop cyanosis. Older children and adults, drinking the same water, did not develop this condition.

According to Comly,[3] there are a number of factors which make an infant more susceptible to nitrate cyanosis than older persons. The most important single factor, in his opinion, is that the infant has less oxidizable hemoglobin than an adult. Other factors suggested are: that there is a high fluid intake with greater turnover of water in proportion to body weight; that the intestinal flora may contain more nitrite converters; that the infant's intestinal mucosa is more easily damaged and favors absorption of nitrites; that the limited excretory power of the young infant's kidney may favor nitrogen retention; and that nitrate ions may be more firmly bound by infantile hemoglobin because of immaturity of certain enzymes.

According to Ferrant[9] nitrates in well water are probably more toxic for newborn infants than for adults, especially if the infants have digestive disorders. This may be a factor, as 14 per cent in this series had diarrhea.

Cornblath and Hartmann,[4] however, claim that only younger infants develop methemoglobinemia upon ingestion of water containing nitrates, because of the low gastric acidity characteristic of the neonatal period.[19] As a result of experimental work, they postulate that if there is no free acid in the stomach and the pH of the gastric juice is over 4.0, nitrite-producing organisms can exist high in the gastrointestinal tract in sufficient number to reduce nitrates to nitrites before the former can be completely absorbed. In their control group of infants, the gastric acidity was increased by lactic acid milk feeding. In these cases they were unable to produce methemoglobinemia with mixtures containing high nitrate content. This appears to be a reasonable explanation. In three cases of methemoglobinemia in this reported series the pH was 4.5, 5.0 and 5.5, respectively.

One final factor must be mentioned. Apparently, the cyanosis may clear up spontaneously when the infant becomes older. This may be due to the fact, as pointed out by Cornblath and Hartmann[4] and others,[19,25] that the gastric acidity increases in older infants. This was illustrated in this series where three cases occurred in one family, one case in 1941, one in 1942 and one in 1944. All three infants developed cyanosis, vomiting, diarrhea and excessive crying at the age of one week while on a SMA formula. In the first two cases the symptoms cleared up at the age of three months with no treatment and with no change in the farm well water used in the formula. The infant born in 1944 was hospitalized when cyanosis developed, and this cleared up in a few days. On returning to the farm home the cyanosis recurred. Nothwithstanding the skepticism of the family physician, the parents changed the water, with prompt clearing up of all symptoms.

There are undoubtedly, however, other factors, and these are all debatable theories.

In passing, it might be of interest to mention a veterinary disease of similar nature as an interesting sidelight. In the spring of 1949 a herd of cattle in rural Manitoba became ill after eating sugar beet tops.[27] Cyanosis was a prominent symptom, giving the appearance of "purple cows." The blood was chocolate-brown in color and methemoglobin was demonstrated. Methylene blue solution was successfully used in treatment but a number of cows died. Analysis of the sugar beet tops showed a high nitrate content but the water contained no nitrates.

While no such cases in farm animals have been reported in Minnesota, this condition is not new. In 1937 a review[14] was made of similar appearance of "purple cows" which had occurred in Colorado and Wyoming due to eating oathay or straw. This condition has occurred since 1923 and has been called "oathay disease." Methemoglobin was demonstrated in the blood, and the oathay and oats contained large amounts of potassium nitrate. Unfortunately, the water used was not analyzed for nitrate. Apparently horses and sheep may also suffer from this type of poisoning. In certain areas in these two states, other plants such as certain weeds, wheat, barley, and cane sorghum sometimes contain sufficient nitrates to cause methemoglobinemia. It has also been reported in sheep in South Africa.

Résumé of Water Supply Aspects*

Nitrate determinations on samples from water supplies were made in the earlier days of the Minnesota Department of Health but were gradually discontinued as a part of the sanitary analysis with the advent of modern bacteriological methods. The health department's interest in the nitrate concentrations of water supplies in the state has been renewed since the first suspected case of methemoglobinemia was reported at Tyler, Minnesota, in January, 1947. From January, 1947, to January, 1950, investigations were made of all water supplies which were reported to be, or suspected of being, involved in cases of methemoglobinemia. In many instances physicians were interviewed in an attempt to determine whether the problem was more widespread than existing information would indicate. The results of these interviews showed that there were, undoubtedly, many cases of methemoglobinemia which were either not being properly diagnosed or were not reported.

In January, 1949, a communication was sent to all physicians in the state asking them to report any suspected case of methemoglobinemia that

had come to their attention in the past several years. The physicians were also asked to notify the department immediately of any new cases.

A study was made of the 146 old and new cases reported as a result of this communication. Each study consisted of accumulating all epidemiological data and obtaining all pertinent information on the water supply involved. Dug wells were found to be the source of water in 129 cases, and drilled wells in four cases. Eleven of the wells were involved in more than one case and two wells caved in before samples were obtained. None of the wells contained less than 10 ppm. nitrate nitrogen (NO_3N) as shown in Table III. (A concentration of 10 ppm. is the maximum recommended by most workers.[3,27,29])

Only two wells contained between 10 and 20 ppm. NO_3N. Insufficient clinical data were available on both of these cases, and they are considered questionable. The samples from many of the 26 wells which contained 21 to 50 ppm. were collected a year or more after a methemoglobinemia case had occurred, and in some instances the well had been abandoned subsequent to the case of methemoglobinemia. The lowest nitrate nitrogen on a sample collected at the time of the infant's illness was 36 ppm.; the highest was 500 ppm.

From the information obtained on the cases reported early in the study and from data published by other workers,[2,10,11,23,27,28] it was considered desirable to determine what factors might influence the nitrate concentration of water from wells. Among the questions which occurred in this connection were the effects on nitrate concentration of pumping, seasonal variations, location and construction, depth and type of wells, and the geology of the area.

Effects of Pumping on Nitrate Concentration.—In order that sampling errors might be eliminated insofar as possible, it was considered necessary that the effect of pumping and the time of sample collection on the nitrate concentration be determined.

Four test runs were made on three different wells. Three of the runs were made over periods of one hour each, with samples being collected every minute for the first five minutes, and every five minutes thereafter. The fourth run was made with samples being collected every hour for a period of six hours. It was concluded from these pumping tests that no significant change in the nitrate concentration is noted with length of pumping, and that the time of collection of the sample after pumping begins is not critical.

Effects of Seasonal Variation on Nitrate Concentration.—To determine the effects of seasonal variation on nitrate concentration, arrangements were made to have samples submitted from certain specified municipal and private wells at routine intervals.

Municipal Supplies.—During this study, twenty-eight (5.4 per cent) of the 514 municipal supplies in the state were found to contain over 5 ppm. NO_3N; sixteen (3.1 per cent) of these contained 10 ppm. or more. The highest concentration was 27 ppm. in a dug well used as the source for a municipal supply in the section of the state from which most of the methemoglobinemia cases have been reported. The health officer of this community advised all residents not to use this water for infant formulas. No cases of methemoglobinemia have been reported from this supply. Eight supplies, ranging in nitrate nitrogen from 5 to 27 ppm., were selected for bi-weekly sampling which was begun in February, 1949. Samples were collected from the sources of supply and from the distribution system in each instance.

Private Supplies.—Four of the wells involved in cases of methemoglobinemia were sampled bi-weekly beginning in February, 1949. These included two wells which were later reconstructed. The remaining two were dug wells, one at Tyler (Lincoln County), and the other at Woodstock (Pipestone County), both of which were located satisfactorily. A fifth supply, a drilled well located one-half mile west of the reconstructed well at Luverne, was also sampled, although this well was not involved in a case.

These periodic samplings were continued for

*No wells contained less than 10 ppm.

a period of one year. From the data obtained, it is concluded, within the limits of this study, that the nitrate concentration of a well water remains fairly constant and that seasonal variations do not occur.

Effects of Location and Construction on Nitrate Concentration.—An analysis of the data obtained on the location and construction of the 133 wells investigated in connection with cases of methemoglobinemia showed that none was both located and constructed satisfactorily as judged by the standards of the Minnesota Department of Health. (These standards for safe water supplies specify that a well should be located at least 50 feet from all sources of contamination such as barnyards, privies, et cetera. The well should be provided with a water-tight casing which extends at least 10 feet below and 1 foot above the grade. Vitreous and concrete tile, wood, and galvanized sheet metal curbings are not acceptable. A reinforced concrete platform which extends at least 2 feet from the well casing in all directions should cover the well. A tight seal at the pump base and a stuffing box head on the pump are also specified. Pit construction is not approved.)

None of the drilled wells and only thirty-five of the dug wells were located satisfactorily as shown in Table IV. Seventy-four wells were located within 50 feet of a source of animal contamination (barnyard, hog pen, et cetera) and thirteen within 50 feet of a source of human contamination (privy or cesspool). No data were obtained on eleven supplies.

Wood curbing was used in thirty-four wells, concrete tile in seventy. All but thirteen of the 121 wells on which data were obtained had wooden platforms.

Since no conclusions could be reached from the preceding data on the significance of location and construction on nitrate concentration, a survey was undertaken of all school wells in Nobles and Kandiyohi Counties. Wells at farms adjacent to the schools were also surveyed and used as a basis of comparison, since it was believed that the school environment afforded well locations which are normally free of gross organic pollution as contrasted with sites generally found in farmyards.

In the Nobles County Survey, thirty rural school and sixty-four farm wells were studied. The nitrate concentration in the school wells was lower than in the nearby farm wells in all but three instances.

Sixty-eight school and fifteen farm supplies were studied in the Kandiyoki County Survey. Only one of the school wells and six of the farm supplies contained over 10 ppm. NO_3N. Wells for the most part were of drilled or driven construction as contrasted with a preponderance of dug wells in the Nobles County Survey.

From the data obtained on these two surveys, it appeared that school wells containing over 10 ppm. NO_3N occur less frequently than do comparable farm wells. It also appears that in the case of dug and of drilled wells, the location factor does not have too much bearing on whether the water will yield a high nitrate content or not.

In an attempt to further determine the effects of construction on the nitrate content of a well, two wells which were high in nitrate and which had been sampled over a period of at least six months, were reconstructed. The wells chosen were a satisfactorily located dug well of 30-foot depth located outside the city limits of New Ulm in Brown County, and a poorly located drilled well, 71 feet deep, located three miles southwest of Luverne in Rock County.

The upper ten feet of each well were reconstructed so as to eliminate the possibility of contamination entering the well from surface drainage. Sampling of the wells after reconstruction did not show a significant reduction in the nitrate concentration. Therefore, contrary to work done by Sangor,[23] good construction for a depth of ten feet failed to exclude nitrate.

Effect of Depth and Type on Nitrate Concentration.—From a tabulation of the data obtained from all the well studies, it was apparent that there is a greater probability of high nitrate concentration occurring in shallow wells than in deep wells. Dug wells are more frequently the source of water high in nitrate than are drilled wells. It is significant that in the dug wells, a very large percentage (62 per cent) of the wells showing nitrates in excess of 10 parts per million were less than 75 feet in depth. In general, it can be said that, within the limits of this study, nitrate can be expected to occur more frequently in the shallow wells (75 feet or less) than in the deep wells.

Effect of Geology on Nitrate Concentration.—During the period January 1, 1947, to August 1, 1949, the laboratory made nitrate determinations on 2,912 water samples. Approximately 800 were submitted specifically for nitrate determination; the remainder were collected primarily for some other reason. Of these samples, 441 (15 per cent) collected from wells in fifty-five counties contained over 10 ppm. NO_3N. The highest concentration found in each county is charted in Figure 2. The white areas indicate counties in which the highest NO_3N concentration of samples included in this study is less than 10 ppm. The vertical-lined area, predominating in the southwest corner, indicates the occurrence of NO_3N concentrations of over 100 ppm. The southwestern section is the area from which most of the methemoglobinemia cases have been reported.

A review of the geology of the State of Minnesota shows that it is, for the most part, a heavily glaciated area, and that most instances where high nitrates have been encountered have been in wells drawing water from the drift. One characteristic common to the western portion of the state where high nitrates have been encountered is the heavy soil. Those counties which show less than ten parts per million nitrate nitrogen in the northern portion of the state very frequently have lighter soils containing considerable quantities of sand. At the present time, there are approximately ten counties in the southern half of the state which show no wells with concentrations of NO_3N over ten parts per million. It is not known whether more extensive studies would show similar results. Because of the peculiar distribution of water high in nitrates in Minnesota, it would appear that there are certain geological factors which are involved. What these factors are, and the nature of their operation, has not been established by this study.

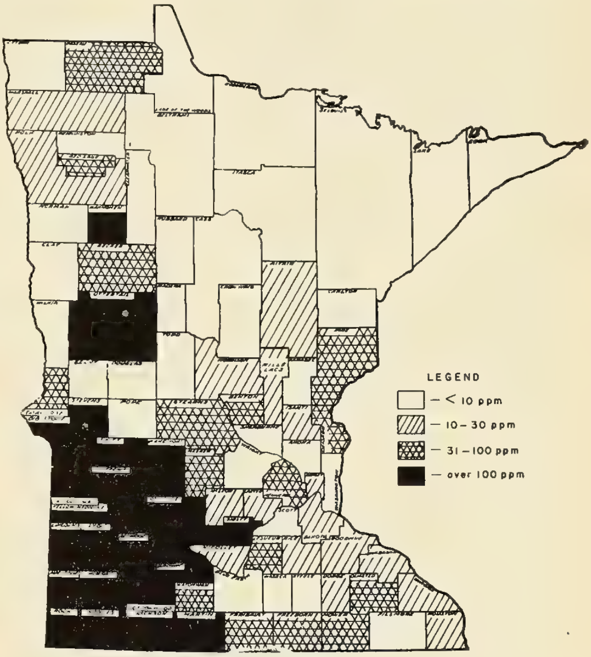

Fig. 2. Nitrate nitrogen concentration in well water. Highest concentration found in county, 1947-1949.

Summary

1. One hundred forty-six cases of methemoglobinemia, including fourteen deaths, due to nitrates in farm well water supplies in Minnesota are reported.

2. Dry and evaporated milk formulas as well as diluted cow's milk formulas which require large amounts of water as diluent are most dangerous.

3. Since no infants who were breast-fed, with one possible exception, developed methemoglobinemia, this would appear to be another argument in favor of breast feeding during the first two months of life, especially in rural areas.

4. Data are presented on water supplies suspected of being implicated in cases on infant methemoglobinemia in Minnesota. In all but two of these cases, the nitrate nitrogen content of the water was in excess of 20 ppm. In the two

exceptions mentioned, the clinical histories of the suspected cases were inconclusive.

5. Test runs on several wells did not show a significant change in the nitrate concentration with length of pumping.

6. Periodic sampling of municipal and private supplies over a one-year period indicate that the nitrate concentration of a well remains fairly constant and that significant seasonal variations do not occur.

7. Studies of rural school wells and similarly constructed nearby farm wells indicate that the nitrate content of the school well water was less than that of water from the farm wells.

8. Reconstruction of two wells failed to show, as some workers thought, that good well construction for a depth of ten feet could be expected to exclude nitrates.

9. Nitrates seem to occur more frequently in shallow wells (75 feet or less), than in deep wells.

10. No method was found by which nitrates could be removed from water. Recently Krueger[12] reported using the resin IRA-400 to remove nitrates from water. This resin works on the anion exchange principle which is similar to the cation exchange that takes place in zeolite softeners.

11. None of the cases of methemoglobinemia in Minnesota on which sufficient data were obtained occurred from using water containing less than 30 ppm. NO_3N in feeding an infant. However, 10 ppm. has been generally accepted as the point above which the water should be viewed with suspicion because of the possibility of a dangerous level being reached through other factors such as boiling.

* * *

Since this paper was written, four additional cases of methemoglobinemia have been reported to the Minnesota Department of Health.

PITUITARY ADRENOCORTICOTROPIC HORMONE (ACTH) IN ASTHMA

J. S. BLUMENTHAL, M.D., F.A.C.P.
Minneapolis, Minnesota

FOLLOWING the elaboration and use of any therapeutic agent, extravagant claims are made. Certainly this has been the case with cortisone and pituitary adrenocorticotropic hormone (ACTH). The very grandeur of the vista unfolded by these agents and the possibilities inherent in them would make exaggeration almost impossible. It is the more advisable, therefore, to report failures as well as successes in their use.

Animals that have had an adrenalectomy show extreme susceptibility to anaphylactic shock as is well known and was long ago demonstrated but when these animals are given cortisone they are protected; and pretreatment injections of ACTH result in only minor reactions.[2] While we know comparatively little about the fundamental processes by which the adrenal corticosterones affect the great changes noted in the body, it is sufficient here to state that there is early in the course of treatment with ACTH or cortisone, physiological changes due to induced hyperactivity of the adrenal cortex; a fall in the eosinophile count; leukocytosis; sodium and chloride retention and associated water retention or excretion; elevated serum carbon-dioxide—combining powers; decreased sodium and chloride in the sweat; increases in urinary histamine, corticoides and seventeen keto steroids; increased gluconeogenesis with hyperglycemia; a diabetic-type of dextrose tolerance curve and increased deposition of liver glycogen; decreased inorganic serum phosphorous; increased uric acid excretion; decreased free serum cholesterol; increased calcium excretion; and a negative nitrogen balance.[4,5] In considering the effect of ACTH on allergic persons, in particular, we must also consider the euphoria induced, and the increased appetite and neuropsychiatric changes.[5] Interference with acetyl-choline cycle as reported by Torda and Wolff[9,10] with at times deficiency and at other times enhancement of *in vitro* synthesis is another important factor. Large doses of steroids have also been reported, by Selye,[8] as hypnotic in effect while Archer[1] in a recent letter in the *A.M.A. Journal* stresses the relationship of the pituitary adrenal axis to fat metabolism and to fatty infiltration of the liver—changes also associated with pregnancy and jaundice—conditions which at times benefit arthritis as well as asthma.

While the conditions treated with ACTH have included almost all serious ones the body is heir to, some of the most dramatic results have been reported in the field of allergy with just about 100 per cent at least encouraging though temporary results. Rose treated six patients with severe asthma.[7] The first two patients received 150 mg. of ACTH daily for two days and 100 mg. daily for two more days. The next four received 100 mg. daily for three days, 75 mg. daily for two days and 25 mg. the sixth day. He reports complete success in relief of asthma in four patients within forty-eight hours. The other two patients while not completely free of symptoms were decidedly improved. Though apparently only remissions, the results were certainly striking for the type of patients reported. Bordley[3] treated five patients with severe asthma with daily doses of 30 to 100 mg. of ACTH given at six hour intervals. Here also marked relief was obtained in four to forty-eight hours. Total ACTH given varied from 360 to 775 mg. Not only was the asthma relieved but in two patients nasal polyps disappeared though they recurred in twenty-three days and one month respectively. Randolph[6] reports thirteen cases of very serious asthma, two seasonal ragweed asthma and eleven perennial advanced cases of this disease. The majority would certainly be included in that terribly discouraging class of asthmatics referred to by Rockemann as "intrinsic;" and were further complicated by nasal polyps and aspirin sensitivity. As he points out these cases were chosen because of their very difficulty as diagnostic and therapeutic problems. Ten of these eleven severe asthmatics obtained marked relief of symptoms and remissions for from one week to five months following treatment with ACTH. Total dosage was 125 to 325 mg., while one patient could not be treated with the usual method and dosage due

---

to fluid retention. The degree of relief varied from 50 per cent to complete comfort—the more satisfactory results being in patients with no clinical or x-ray evidence of emphysema, empyema or scarring. Even in those having recurrence of bronchial asthma after treatment, symptoms were "readily relieved following the inhalation of small amounts of epinephrine spray"—in decided though temporary contrast to the pretreatment condition. Their general status improved markedly—a condition not due to suggestion as placebos did not work in the same manner.

Because of these reports, it is to be understood that the privilege of being able to use this drug was greeted by me with great enthusiasm and anticipation. The first two patients, I decided, would be really "tough ones"—whom I had followed, and used up my total therapeutic armamentarium as well as that of other men in the field. As the material was to be given every six hours and in order to follow the response to treatment especially as to the eosinophile count (to be sure the adrenals did respond) the patients were placed in a hospital. This was done in spite of the fact that, as is well known, hospitalization and rest are often great therapeutic agents in themselves which could very easily confuse one as to the real agent responsible for improvement. In these people, however, because of the length of previous observation, I believed I could easily detect real improvement if it resulted as promised.

Case 1.—This patient, a man, aged forty-five, married, working in a furniture shop, has had asthma for twenty years. He has had a perennial associated stuffy nose with "sinusitis" for fifteen years. His asthma is aggravated by exertion, excitement, laughing, and changes of temperature. For the past ten years, he has had attacks at least once a night and he uses adrenalin by spray and aminophyllin suppositories with only partial relief. He was not appreciably improved by a stay in Arizona. Iodides, ephedrin, dietary regimes, desensitization with dust, fungi, vaccine, histamine have all been of little help. He has been hospitalized on many occassions and for varying periods for status asthmaticus. His past history is not remarkable except for nasal surgery fifteen years ago with poor results. His routine blood and urine were negative. The sedimentation rate was six. X-ray of the chest and electrocardiogram gave negative findings. This patient has been under my care since May 1949, and all usual procedures, including the antihistamine, antibarium, and antibiotic drugs were of no help. He was given 260 mg. of ACTH for a period of seventy-two hours with no marked benefit, on either the symptoms or vital capacity while in the hospital. That the adrenals did respond was shown by the drop in the total eosinophile count from 90 to 0. The drug was given every six hours.

Case 2.—This patient, a woman, aged forty-nine, married, a former nurse and present hotel proprietor, gives a history of asthma since 1943. She also had a perennial stuffy nose in 1947 and 1948 but no asthma at that time. The condition is aggravated by hard work, dust, colds, and cold air. Partial relief is at times obtained by aminophyllin, ephedrin, and adrenalin by hypo. The past history is not remarkable except for irrigation of the sinuses in 1949. The physical examination, x-ray, and electrocardiograms were normal. Routine blood and urine examination were not helpful. This patient has been under my care since January, 1950, and the usual procedures including elimination diets; sedation; desensitization with dust, fungi, vaccine, histamine; antihistamine, antibarium, and antibiotic drugs were tried but in May 1950, she became very seriously incapacitated by her condition and a trial of ACTH was advised. ACTH was given for 96 hours for a total of 360 mg. with no marked effect. The total eosinophile count showed the adrenalin stimulation by a marked drop from 16090 to 680 to 90 to 0. As a matter of fact she required repeated hypos of adrenalin and aminophyllin while being given ACTH as well as after treatment. The drug was given every six hours.

Case 3.—This patient, a man, aged fifty-six, married, is a patient of Dr. Henry Ulrich. He has had asthmatic attacks since January, 1950, and had a particularly difficult period while in Houston, Texas. His past history is non-contributory except that he has had nasal polyps for many years which have been removed periodically every six months. Duodenal ulcer in 1949 improved under diet. He is extremely sensitive to aspirin. He claims he is allergic to tomatoes. Physical examination was practically negative, except for nasal polyps. His chest, whenever examined, was clinically free from asthma. The usual therapy (bronchodilators) including rest and sedation improved the patient somewhat. After one week of hospitalization he was discharged on May 25, 1950. His routine blood and urine examinations were negative. The eosinophile count was 5 per cent. On June 2 and 3, he received 80 mg. of ACTH at twelve-hour intervals for four days. Three days later he reported no improvement in his attacks but he said his cough seems less and his polyps "were gone."

It is difficult for me to understand the effect of ACTH in these three cases of asthma—a disease in which therapy is very difficult to assay in view of the tremendous psychic factors. The dosage was as reported; the response of the adrenals was certainly there, as noted in the eosinophile counts. It also seems that, if relief is to be obtained,

RENAL TUMORS

HENRY FISKETTI, M.D.
Duluth, Minnesota

THE FOLLOWING material resolves itself into a generalized discussion of renal tumors, which is a group none too common but most interesting. It is far from being exhaustive or even a beginning review of the literature on the subject, but if it does nothing more than give a brief review of their clinical and pathological features, their incidence, etiology, symptomatology and so forth, its aim will have been fulfilled. It is also an attempt to evaluate and correlate the pertinent facts about all the cases in the hospital records.

The cases surveyed were those dating back twenty-six years in the records of St. Mary's Hospital, Duluth, and include all kidney tumors that have been classified since the inception of adequate record room files. The cases in this survey include only those that have been proven to be kidney tumors, either by surgical removal and pathological specimen or at autopsy. Up to 1936, there were only twenty-five proven cases listed. So we see that over half of the cases have been recorded since that time. Better investigative urology and more autopsies have brought many to light, no doubt. The total series is not large but sufficiently comprehensive to justify some conclusions and we must not lose sight of the fact that their incidence in the realm of neoplasm is comparatively rare. Some of the cases, it is admitted, were not diagnosed clinically but were incidental findings in routine autopsies.

The classifications of renal tumors are almost as multiple as those of arthritis and much recently acquired knowledge as to their pathology has cleared up this phase considerably. There are both the malignant and the benign. From a standpoint of interest, a typical classification of renal new growths about thirty years ago was chiefly a pathological one. They were divided into three groups.

Group I—Composed of those that took their origin from the cells of the adult or fetal kidney. These were called "homologous" growths and consisted of:

A. Benign
  1. Connective tissue origin (fibroma (lipoma (fibrolipoma (angioma
  2. Epithelial origin (papilloma (adenoma

B. Malignant
  1. Connective tissue origin
    (a) round cell } mesodermal
    (b) spindle cell } mesodermal
  2. Epithelial origin—epitheliomata or carcinoma.

Group II—Composed of those that take their origin from cells or tissues that do not belong to the kidney proper, but which have been included in this organ during its development. These were called "heterologous" growths and included:

A. Large fatty tumors, the "struma lipomatoides aberrata renis" of Grawitz which he described in 1883 and which are now termed hypernephromata, the name coined by Lubarsch in 1894.

B. Mixed growths
  (1) of muscle, bone, or cartilage.
  (2). rests from Wolffian body.
  (3) mesodermal rests—so-called Wilms' tumors.

Group III—Comprised of those enlargements which are tumors in a clinical sense only, and which form a pathological standpoint are retention cysts due to a non-patency of renal tubules.
  1. Single solitary cysts.
  2. Congenital cystic kidneys.

This is essentially an outmoded and bulky classification based on embryological etiology and derivation. Since Grawitz's paper of 1883, a tremendous amount of literature has accumulated dealing with classification, but most of the discussions are concerned with either disproving or proving the etiological adrenal rest theory of Grawitz. The latter's supporting arguments are:

1. Their position under the capsule of the kidney where adrenal rests are often found normally.
2. The cells of hypernephroma are similar in type to adrenal cells.
3. Characteristic fatty infiltration of the cells which is never found in kidney epithelium.
4. The presence of a limiting capsule around the tumor.
5. The arrangement of cells is similar to that in the adrenal cortex.

The opposition to Grawitz's hypothesis as advanced chiefly by Stoerck in 1908 and by Glynn in 1911 believe that:

1. Grawitz tumors are more frequent in the lower pole where adrenal rests are not found.

2. So-called fat cells of the hypernephroma are not fat but vacuolization related to the glycogen content of the cells.

3. It is a tumor of the cortex and not the capsule in which adrenal rests are formed.

4. That renal tumors never influence the growth of sexual characteristics as one would expect from superfluous adrenal tissue.

5. Finally, why should adrenal rests which are comparatively rare in the kidney produce hypernephroma which is the commonest kidney tumor while rests in other localities, although comparatively common, so rarely produce tumors?

TABLE I.

BENIGN	MALIGNANT
Adenoma	Hypernephroma-adenocarcinoma of renal cortex
Fibroma	Carcinoma
Lipoma	1. Adenocarcinoma-hypernephroma
Angioma	2. Papillary carcinoma
Papilloma (includes pelvis)	3. Squamous cell or Epithelioma
Cysts	Sarcoma
	1. Round
	2. Spindle
	3. Mixed
	Embryoma or Wilms' tumor
	1. Teratoma
	2. Rhabdomyoma
	3. Mixed tumors

TABLE III.

	Barney	Braasch	Senator	Creevy	St. Mary's
Male	43 (58.1%)	51 (61%)	199 (65%)	59 (63%)	34 (59%)
Female	31 (41.9%)	32 (39%)	106 (35%)	35 (37%)	24 (41%)

At present, it may be stated that hypernephromas are peculiarly different histologically and stand out as a separate group. Their exact origin is still unsettled but there is now a fairly general acceptance of its renal rather than adrenal origin. The best grouping of kidney tumors to our mind, is not one which is on a pathological or etiological basis but a practical one of value clinically to the average practitioner who has forgotten a very liberal amount of pathological detail.

Table I constitutes a more simple and workable classification.

In incidence, hypernephroma is by far the most common in the adult while in children the embryomata or Wilms' tumor comprises the majority. Table II presents the incidence of tumor types for three other series in addition to our own.

It will be noted that in Smith's cases, the tumors are all malignant except two which were thought to be fibromas and, furthermore, that hypernephroma is the most common in all series. The percentage of these in our series, that is 58 per cent, is similar to the others. The average percentage of incidence in the four series is 57 per cent. The incidence of other tumor types in the various series differ widely sometimes, but this is probably due, in part, to the fact that different pathologists, each having their own individualities in pathological judgment and criteria, made the diagnoses. A microscopic section to one may appear as an adenocarcinoma while by another it may be interpreted as a cystadenocarcinoma, etc.

Let us consider incidence from the standpoint of sex. Most writers state that males are affected more than females, offering no explanation for this difference (Table III).

Heredity and trauma are not causative factors but trauma may be a precipitating cause of hemorrhage in a tumor already existent. Kraft reports a case of a man being struck by a plow following which he developed a mass in the flank. This remained the same for eighteen years but later at operation, there proved to be a superimposed medullary carcinoma. In our series, a man kicked by a cow nine months previously developed a carcinoma of the renal pelvis, but, of course, this may have been coincidental. It could be significant.

TABLE IV.

Years	Senator	Koster's Table (Keyes)	Creevy	St. Mary's
0–9	157	169		7
10–19	15		1	1
20–29	34		3	1
30–39	45		2	
40–49	42	125	22	8
50–59	96		22	17
60–69	57	128	30	18
70–79	13		1	5
80–89				1
	459	422	81	58

In Table IV, it will be seen that renal tumors are most prevalent during childhood and late adult life. At St. Mary's forty-nine of the fifty-eight cases were in patients over forty years of age.

Kelynack has also tabulated 160 cases, more than half of which occurred in the first decade of life; only fifteen between the ages of nine and thirty-five; and of the rest, over 50 per cent between the ages forty-five and sixty. Walker reports that almost all sarcomas occur in children before the fifth year (116 out of 138 cases). At St. Mary's three sarcomas occurred in adults and three in children.

Symptoms

The symptomatology of renal tumor is well defined. Hematuria, pain and tumor mass are the classical triad but it is not obligative that all these be present. When all are present, the growth is far advanced and beyond cure. *Hematuria is the most important symptom.* In eighty-three cases, Braasch found the first presenting symptom to be hematuria in 47 per cent, pain in 32 per cent and tumor in 15 per cent. Hinman found all three sypmtoms in 38 per cent. At St. Mary's, pain was present in 58 per cent, hematuria in 45 per cent and mass both subjectively or objectively palpated in 48 per cent. All three symptoms were found in only 6 per cent of the St. Mary's group. Hematuria in the beginning may be only microscopic but gross hemorrhage often results in clot formation with ensuing renal colic as the clots pass down the ureter. Bleeding may be spontaneous, and recur at long intervals of time which may lead to procrastination as to timely and proper investigation. In children, hematuria is notoriously absent. Dexter found hematuria in only one of forty-one in children and two French writers in 39 and 29 per cent respectively. As far as I could determine, no gross hematuria was recorded in our small group of children.

The second striking symptom is tumor mass which on palpation may be hard and nodular or soft and smooth. Many of the patients are aware of this mass and others experience only abdominal discomfort or fullness. Before extension outside the kidney, it is usually movable. With proper technique, that is, bimanual pressure, at the end of deep inspiration, with the patient in the lateral prone position, Israel was able to palpate enlargement in sixty-two of sixty-eight cases and Smith in sixty-eight of eighty or 84 per cent. "Ballotment renale" or Guyon's sign is sometimes elicited. In the St. Mary's series, tumor was found in 48 per cent.

Pain is probably the least diagnostic symptom. When not due to clot-passing with typical renal colic, a constant dull ache may be due to hydronephrosis, pull on the renal pedicle, or to involvement of adjacent nerves. There may also be pressure symptoms such as varicocele, due to compression of the spermatic veins or ascites and edema of extremities by pressure on the larger intro-abdominal veins. Intestinal obstruction may be caused by tumor pressure. Other associated symptoms, and sometimes the presenting symptoms, are gastrointestinal disturbances such as anorexia, indigestion, constipation, or diarrhea. Jaundice may be present if a right sided growth has extended to the liver. In the late stages, anemia and cachexia predominate. Patients presenting these symptoms are the ones in whom valuable time has been lost in arriving at a diagnosis and the ultimate prognosis thereby made worse. In a few cases, the symptoms from metastases to lungs and bone may be the first indication of the presence of the lesion. In one of our cases, a pyelonephritis of the opposite kidney obscured the true diagnosis for several months.

Fortunately, rapid avdances in the betterment of cystoscopic instruments and technique, have greatly facilitated the diagnosis of renal tumors. Before the development of intravenous pyelography, many cases of tumor were not diagnosed early because more troublesome cystoscopy was repeatedly postponed. It must be emphasized that all hematurias, painless or otherwise, should have exhaustive investigation and not be lightly passed off with the admonition that "if it happens again we'll look into it more thoroughly." It may be too late then for permanent cure. Retrograde pyelography has no peer but the intravenous technique is helpful as corroborative evidence and as a screening test. A negative intravenous pyelogram, however, should not be considered conclusive.

Too much reliance, on the other hand, must not be placed on a definite diagnosis from a pyelogram alone. Few show absolutely typical pictures with "spider leg" deformity of the calices, but the greater number show only partial filling defects of the pelvis. In practically all of our series, the x-ray diagnosis was merely "filling defect of the renal pelvis." Therefore, we see that the history and clinical findings, cystoscopy with pyelography and renal function determination are equally indispensable for early diagnosis.

A few more facts about the St. Mary's series. Presenting symptoms had been present for an average of about forty weeks. There were twenty-seven cases with proven metastases, or 49 per cent. These metastases were chiefly to the lung in thirteen cases or 45 per cent, to the bones in eleven cases or 40 per cent, to the lymph glands in eight cases or 30 per cent, and to the liver in five cases or 22 per cent. The bone metastases were chiefly to the spine and pelvis; one to the jaw and several to the ribs. Lymph gland involvement is usually to the retroperitoneal, cervical or mediastinal nodes. Renal function determinations such as P.S.P., indigo carmine, and blood chemistries were done in only twenty-seven or 47 per cent. It would seem that these procedures should have been done more frequently as part of a thorough urological investigation, even though not much information is usually gleaned from this source. Generally speaking, these function tests were usually reduced on the side of the lesion but rarely were the blood metabolites elevated, which is what we would expect with the other remaining kidney present and normal. Blood chemistries were done in only twenty-five cases. It is amazing that more blood chemistries were not done prior to nephrectomy because the latter would certainly be contraindicated in a semiuremic or uremic surgical risk. One such instance occurred where a nephrectomy was done in a case with an admission blood urea nitrogen of 76 and a creatinine of six- with death on the first postoperative day. Certainly, this was poor surgical judgment.

Associated diseases were irrelevant and commonplace but hypertension and urinary tract infection were quite prevalent. Varicoceles were present in two patients, and it is interesting to note that one case of adenosarcoma in a three-year-old was superimposed on a horseshoe kidney. The average hemoglobin was 62 per cent and the red blood cells 3.36. Positive urinary findings, either r.b.c., w.b.c. or albumin were present in 64 per cent. Three biopsies of a cervical gland, of bone and of the liver confirmed the diagnosis of hypernephroma in three instances. In one patient, simple pyelotomy was done for palliation.

Concerning the treatment of renal neoplasms, suffice it to say that early surgery plus preoperative or postoperative radiation or both, offers the only chance of complete cure. And, of course, it must be taken for granted that the kidney function in the remaining kidney is compatible with life. A thorough study should be made for metastases and many writers feel that even the presence of small or early metastases does not necessarily contraindicate nephrectomy.

Creevy believes that irradiation of metastases and recurrences is of definite value. Whether life is prolonged is debatable but there can be no doubt as to its palliative values in reducing pain. Dean believes that pulmonary metastases are radio sensitive and that bone lesions are not. Creevy believes they both respond equally. Most men feel that x-ray generally does not appreciably affect the percentage of cures. One point of note is that preoperative radiation may reduce a tumor in size to the point where it may be operable, whereas previously it was not. It seems to be rather generally agreed that x-ray treatment is most useful and is the best treatment for Wilms' tumor. Many men state that surgery is of no avail but it seems to me that every early case should have the benefit of surgery. Better results from x-ray therapy at the present day is expected because of improved techniques; high voltage machines, et cetera.

The percentage of five-year cures by all types of therapy are not too encouraging. The over-all average of five-year cures in percentage from a series of cases reported by Walters, Priestly, Braasch, Hyman and about five other authors is 23 per cent. This low percentage certainly speaks eloquently for early diagnosis. I could find no report of a five-year cure for a Wilms' tumor.

In the cases at St. Mary's, nephrectomy was done in 55 per cent. X-ray therapy was used in only 21 per cent of the cases. It was not possible to arrive at any definite percentage of five-year cures because of the insufficiency of follow-up data on the charts.

Conclusions

1. Much progress has been made in the classification and etiology of renal neoplasms in the last twenty years. The renal origin of hypernephroma is more tenable.

2. The classical symptomatic triad is pain, hematuria and mass and when all are present, the tumor is beyond all hope of cure.

3. Generally speaking, our cases compare favorably with other series reported as to age, incidence, tumor types and symptoms.

4. Surgery, if it is to be of any avail, must be done early and small metastases do not necessarily preclude surgery.

5. X-ray is a valuable adjunct to surgery and that it reduces pain, also.

6. Every case presenting one or more of the classical renal symptom triads should be cystoscoped immediately and studied urologically.

7. The charts studied in the series at St. Mary's were deficient chiefly in two categories:

(1) Poor follow-ups for evaluation of therapy and estimation of five-year cures.

(2) Many tests and investigative procedures done before admission had not been recorded and were, therefore, unknown. Incorporation on the hospital chart of such data would be of inestimable value in any statistical analysis.

PITUITARY ADRENOCORTICOTROPIC HORMONE

(Continued from Page 797)

we should get it fairly soon, as has been reported. Furthermore these patients did not have emphysema or other pulmonary diseases. Perhaps more prolonged or more intensive treatment is indicated. At any rate, here are three patients with severe asthma who did not respond to ACTH—a rarity, at least at present, in the literature of this remarkable drug.

Acknowledgment

I wish to thank Dr. Henry Ulrich for the use of the data on his case, and Dr. Edmund Flink for furnishing the ACTH.

History of Medicine In Minnesota

MEDICINE AND ITS PRACTITIONERS IN OLMSTED COUNTY PRIOR TO 1900

NORA H. GUTHREY

Rochester, Minnesota

(Continued from July issue)

Lucy J. Bolt (Mrs. James H.) Easton, "magnetic healer" and "clairvoyant healer," holder of state exemption certificate No. 179-3 (filed in Olmsted County on October 23, 1883), was from the early eighteen sixties into the first decade of the twentieth century a practitioner in Olmsted County, in and near Rochester. She was a handsome woman, tall, large and blonde, kindly and sincere, an interesting character. Although conflicting statements are heard as to her merits as a practitioner, there is agreement that she had a large clientele who believed in her healing powers, and that certain established physicians of the regular school, although they would not consult with her, nevertheless on occasion advised patients to go to her, not for physical healing but "for the psychologic effect." As a highly respected person has said, "She really was magnetic and had a sense of diagnosis and treatment." One has only to mention her to old residents to hear anecdotes about her procedures and beliefs as a healer, and about her eccentricities; for example, she raised innumerable canaries, using the family living rooms as an aviary.

Lucy J. Bolt was born in New York State and came with her parents, pioneer farmers, to St. Charles Township, Winona County, in the early fifties. In 1856 she was the second teacher to preside over the district school of the township; in the autumn of that year she was married to James H. Easton, who was by turns innkeeper, farmer and photographer. Mr. Easton was a native of Massachusetts, it is said, the son of an itinerant herb doctor and journeyman carpenter, who sometimes was employed as a workman in the East by Henry Wadsworth Longfellow. The only child of James and Lucy Easton was James Hamlet Eugene Bolt Easton, born about 1859, whose magnificent baritone voice gave him place at social, church and public functions and supported him during his seven years as a law student (nongraduate) at Harvard University. In that period, the late seventies and early eighties, he once was a guest at the Longfellow home; the poet was interested, the story goes, in hearing from a native Minnesotan how "Hiawatha" was regarded in its locale.

In 1860 Mr. and Mrs. Easton established "the first art gallery" in St. Charles; in December, 1862, in Rochester, they were erecting a building on Broadway to house their photographic equipment. In the next decades, with Lucy Easton always her husband's assistant as well as a practitioner, they were in different locations. Sometimes the gallery was their home, and for many years they lived on their farm, three miles south of town on what is now Highway No. 63. By the eighties the Eastons had become the owners, and Hamlet the driver, of blooded horses, which they entered in races over a wide circuit of noted tracks in many states, with varying profit and loss. Of their horses, Badge, a splendid black pacer, "put Rochester on the map as far as turfmen's eyes were concerned." Others were Lebbius I. (originally from Eyota and named for Lebbius I. Ingham, a leading citizen of that village), Hal Crags and Pico. In August, 1896, the *American Sportsman*, quoted by the *Rochester Post,* declared that on every day that Badge was to race, Mrs. Easton would hold a séance and would telegraph her son the spirits' dictum, so that he might govern his pool of tickets accordingly.

From her ealiest arrival in Rochester, it has been recalled, Mrs. Easton held séances and began her magnetic healing, but it was not until later that she styled herself a practitioner of medicine and probably not until the eighties, after she had received her state exemption certificate, that she assumed the title of "doctor." In August, 1887, when her controversy with the city council was being aired in the *Rochester Post,* she stated, "Although I have practiced the healing art in this city upwards of seven years, I have never, nor have friends of my patients had occasion (except in a single instance) to send for an undertaker where the case has terminated in my hands." This was with regard to her alleged opinion on the condition of a young man who had been injured on July 4 by a gunpowder explosion when a cannon was fired during a civic celebration. The patient's mother had rejected the services of Dr. W. W. Mayo, "would have nobody but Mrs. Easton." Mrs. Easton, it was stated, had declared the patient dead and had sent for the undertaker, and had in due time presented a bill of $20 to the city. The report continued, "The council would pay for a physician, but would not pay for Mrs. Easton." An additional note was that when Mrs. Easton had left the patient's home, Dr. E. W. Cross was called, and that the patient was restored to health.

Many of Mrs. Easton's patients consulted her at the studio or the home, but often she was called into the city and the countryside. An early resident of Rochester, Oliver J. Niles, of Grand Rapids, then a boy in his teens, has said that when the Eastons were living on the farm, he often was sent out by different Rochester citizens, persons of comfortable circumstances and unquestioned judgment, to summon Mrs. Easton. In the office she conducted her treatments unaided; whenever she was called to the home of a patient, her husband accompanied her, and his knowledge of medicinal herbs that he had gained from his father was combined with her magnetic powers.

In the last years of the Eastons' life in Rochester their fortunes declined. In 1909 the noble racehorse Badge died. Before 1911 the family had removed to Florida.

Roswell Eaton (1823-1884), a resident of Rochester, Minnesota, from 1867 to 1884, did not practice his profession actively in the city. He was born in Sardinia, Erie County, New York, in 1823, and in 1841 removed with his parents to Walworth, Wisconsin. At Geneva, Wisconsin, he studied medicine with a Dr. Palmer, before attending lectures "at the medical college, Chicago, from which institution he graduated in 1856." He practiced medicine in Sharon, Wisconsin, for the next ten years, and in 1867 came to Rochester accompanied by his wife, Patience Matteson Eaton, a native of Shaftsbury, Vermont, to whom he was married at Sharon in 1857. There were no children of the marriage.

In Olmsted County, living on a tract of land at the northern limits of Rochester, Dr. Eaton had his chief interest in farming and dairying. His name appeared often in the newspapers of the city in connection with the Farmers Institute, a creamery in Rochester, and so forth. In the great cyclone of August 21, 1883, his house and barn were demolished and Dr. Eaton, carried several rods with the debris, was injured severely. On September 14, 1884, while helping a threshing crew on his place, he died suddenly from heart failure. In his obituary he was described as having been a Baptist, an upright citizen, a scholarly and well-informed man. Patience Matteson Eaton survived him twenty years, dying in early March, 1904, at the age of eighty-three years; her only surviving relative was her brother, Langford Matteson, a farmer north of Rochester.

Cyrus Bowers Eby (1872-1934) was the fifteenth appointee, in July, 1893, as an assistant physician on the staff of the Rochester State Hospital, Olmsted County.

It is well known that Dr. Cyrus B. Eby for nearly thirty-three years, from 1901 until his death, was a loved and honored physician of Fillmore County. It perhaps is not so well known that for nine years, three as a medical student and six as a physician, he was associated with Olmsted County. In an article, "Notes on the History of Medicine in Fillmore County Prior to 1900" (Guthrey) there appeared a sketch of Dr. John Robert Eby, elder brother of Dr. Cyrus B. Eby, which included detailed information on the Eby family and tribute to Dr. C. B. Eby as a physician of Fillmore County *after* 1900.

The fifth of seven children, Cyrus Bowers Eby was a son of Aaron Eby, M.D., physician and writer, and Matilda Croft Bowers Eby. He was born in Sebringville, Perth County, Ontario, Canada, on December 9, 1872, and received his early education in the public school at Sebringville. Later he attended Stratford Collegiate Institute, Stratford, Ontario, from which he was graduated in 1889. Soon afterward he came with his brother John Robert to Minnesota, where his uncle, Dr. Jacob Eton Bowers (q.v.) a distinguished alienist, had been established since 1868 (the first superintendent and chief physician of the state hospital in Rochester from January, 1879, to October, 1889).

During the summer of 1889 and during vacations in subsequent summers, Cyrus B. Eby was employed as a clerk, as was his brother before him, in the drug room of the state hospital. In the autumn of 1889 the brothers matriculated in the medical department of the University of Minnesota for a course of three years, which they completed in 1893. Cyrus B. Eby, an honor student and a member of medical fraternity Nu Sigma Nu, was then only twenty years old, so that he was obliged to wait until his majority to obtain his Minnesota state license to practice medicine.

Dr. Eby came to Rochester on graduation and, it is said, was employed at the state hospital as an intern until his appointment as an assistant physician could become effective. His years in Rochester were marked by able professional work and study and by the activity in medical societies that continued all his life. He was in due time a member of the official medical societies of Olmsted County and of Fillmore County and of the Olmsted-Houston-Fillmore-Dodge County Medical Society, and of the Southern Minnesota Medical Association, the state medical association and the American Medical Association.

On July 8, 1896, Cyrus B. Eby was married to Laura Blanche Bamber, of Rochester. Mrs. Eby was one of the eight children of Dr. Archibald Bamber, a pioneer dentist of Rochester, and Susan L. House Bamber, who was a native of Dixon, Illinois, a daughter of John W. House and Mary A. House. The parents of Archibald Bamber were John Bamber and Lucy Whitney Bamber, who came to Rochester from Ohio in December, 1854, and pre-empted farm lands bordering the Zumbro River near the city; John Bamber was the son of David Bamber, native of Londonderry, Ireland, who came to Herkimer County, New York, in 1798.

Early in 1898, Dr. Eby took a postgraduate course in the diseases of children, at the New York Polyclinic Medical School and Hospital. In February, 1899, he resigned his position at the state hospital and entered private practice at Hospers, Iowa. Later in 1899 he went into northern Minnesota, where for a time he was mine physician at Mountain Iron. Early in July, 1901, Dr. and Mrs. Eby with their young daughter and their infant son settled in Spring Valley, Fillmore County, Minnesota.

For many years Dr. Eby was a member of the board of health of Spring Valley and a county physician. During World War I he carried the burden of practice while other local physicians were in military service, and was medical examiner for the local draft board. He was a member of fraternal organizations, among them the Masonic Lodge (A. F. and A. M.), and was an active worker in the Baptist Church. A talented and enthusiastic gardener, he beautifully landscaped the grounds of the church as well as the grounds of his home. His chief happiness was in his family and home, his recreation in nature study and fishing.

Dr. Eby's hesitancy to send bills or to ask payment of his fees was common knowledge. A favorite story in his family was of the almost unique occasion, in the lean years of the early nineteen thirties, on which he determined to ask a certain farmer for a payment on bill of long standing. When he called at the home, the farmer was away, and Dr. Eby therefore explained his errand to the man's wife. She said, "Oh, I am sure Tony couldn't pay you anything now, because he had trouble getting money together to go on this fishing trip." Dr. Eby said no more; probably he felt some little sympathy with his fellow enthusiast.

Kindly, even-tempered, and selfless in his devotion to his work, an able and ethical member of his profession, a general practitioner of the highest type, Dr. Eby held the friendship and esteem of his colleagues as a man and their respect as a physician. To his patients he was friend and much sought adviser in their personal affairs as well as doctor. He is remembered perhaps especially for his consideration of the needy sick and for his love of little children and his skill in caring for them.

Dr. Eby died on January 20, 1934. Although not well, he had answered a call some ten miles in the country; the road was blocked with drifts, he was alone in his automobile, and in order to get through had to shovel snow and to apply tire chains and, when one chain was lost, to wind rope around the tire. When he arrived at his destination he tried to conceal his exhaustion. As he sat in a chair drawn up to the patient's bedside, he remarked that he had "a little heart trouble," and fell forward in death. In a memorial tribute published in MINNESOTA MEDICINE it was written of him "Words cannot add to the nobility of Dr. Eby's life. Most doctors would envy the way of his life and its ending."

Dr. Cyrus Bowers Eby was survived by his wife, Blanche Bamber Eby; a daughter, Esther E. Eby, member of the faculty of the University of Houston,

Houston, Texas; a son, Robert A. Eby, of Duluth; two brothers, John Robert Eby, M.D., of Elko, Nevada, and Frederick Eby, Ph.D., LL.D., of Austin, Texas; and two sisters, M. Dorothy and Grace D. Eby, both of Trenton, New Jersey. Mrs. C. B. Eby died on April 20, 1941. Of the relatives named here, there were living in 1946, at the addresses given, Miss Esther E. Eby, Robert A. Eby, Frederick Eby, and Miss Grace D. Eby.

Alexander Elder around 1865 relinquished his medical practice in New York City and came to Rochester, Minnesota, where his brothers James and William had established a mercantile business. A third brother, John, was a farmer near by in Cascade Township. Dr. Elder practiced medicine in Rochester perhaps two or three years before he removed to Eyota to make his home with his daugher, Mrs. C. Smith Andrews. Later he divided his time between Minnesota and New Jersey.

A reference to him as a physician is that of Charles Nicholas Ainslie, in his privately printed memoirs, At the Turn of a Century (1938). Charles Ainslie never forgot a morning on which the temperature was 20 degrees below zero, when he, a small boy, "was bundled up to walk more than two miles on a road drifted during the night, to get word to Dr. Elder . . . to come and relieve father," who had suffered all night. "Father" was the Reverend George Ainslie, as stated earlier, the first Presbyterian minister in Rochester; the Ainslie family then lived in a farm home at the foot of Indian Ridge north of town.

Early in 1875 the *Rochester Post* carried a notice of the sudden death of Dr. Alexander Elder, from heart disease, on February 3, at the home of his daughter at Westfield, New Jersey: "He was a gentleman of superior scholastic acquirements and sterling character."

Ziba H. Evans, a graduate of the Medical Department of the University of Buffalo (New York) in 1872, practiced medicine briefly in Rochester, Minnesota, in the summer of 1879; in August, after six weeks, he left for Elk River, Michigan, to take the position of physician and surgeon for a large rolling mill in that city. Official medical directories show that he was licensed in Michigan in 1902 and that from 1906 or earlier, through 1916, he was a practitioner in Traverse City, Michigan.

L. E. (Leo Ervin Oscar) Evens, a graduate of the St. Louis College of Physicians and Surgeons early in 1897, came that spring from Alexandria, Minnesota, to Rochester. For several weeks in May and June, resident at the Rochester Hotel, he served as locum tenens for Dr. H. H. Witherstine while the doctor was in the East at a meeting of the American Medical Association and on vacation. When Dr. Evens left for Iowa in September, the *Olmsted County Democrat* stated that he had been several months "at St. Mary's" and, as stated, in charge of Dr. Witherstine's office. During his stay in Rochester he became a member of the Southern Minnesota Medical Association, at the sixth annual meeting, at Winona, on August 5, 1897. Dr. Evens was licensed in Iowa in 1897 and in the next twenty years practiced at different towns in the state, Osage, Cedar Rapids and Waterloo. Subsequently he was in Chicago and in Hartford, Connecticut. His death occurred suddenly in California in April, 1934, when he was in his early sixties.

David Sturges Fairchild (1847-1930), a pioneer physician in the village of High Forest, Olmsted County, from 1869 into 1872, lived most of his distinguished professional life in Iowa: in Ames from 1872 to 1893, in Clinton from 1893 to 1930. He was honored in life and has been commemorated since death for his great contributions to the art and science of medicine and surgery and to their literature. Dr. Fairchild's History of Medicine in Iowa (1927) is a monument to him. Certain of his special articles, inimitable reminiscences, give a graphic picture of early conditions of practice in southern Minnesota and particularly in the Olmsted County of the early seventies.

The son of Eli Fairchild and Grace Diamond Sturges Fairchild, David Sturges Fairchild was born on a Vermont farm near the village of Fairfield on September 16, 1847. He came of fine lineage and was reared in a fine tradition. He received his earliest schooling near home and in his fifteenth year began his formal education at Franklin Academy, in a Vermont village near the Canadian border. Two years at Franklin were followed by a year at Barre Academy, a year of teaching district school ("The conditions and compensations of a Vermont district school teacher were less attractive than of a farm laborer."), and a period as apprentice to an established physician during which he read anatomy, physiology and materia medica as set forth by Gray, Dalton and Wood respectively. In the autumn of 1866 he entered the medical school of the University of Michigan, which he found crowded by 525 students, many of them resuming medical study that had been interrupted by military service during the Civil War. He returned to Ann Arbor in September, 1867, for a second term but, finding the school temporarily disrupted by a dispute over homeopathy, he transferred to the Albany (New York) Medical College, from which he was graduated on December 23, 1868.

Following the advice of his friend, Dr. Burney J. Kendall, who had studied with a physician in a neighboring community in Vermont and was now practicing medicine in the village of Marion, Olmsted County, Minnesota, Dr. Fairchild in April, 1869, came to Olmsted County and by May 1 had settled in High Forest. Twenty-three years old, very blond, carefully groomed, his costume made impressive by a plug hat and a Prince Albert coat, he arrived in High Forest on horseback. He was courteous, friendly and tolerant, in a reserved New England way, and was obviously of culture and education superior to that of most of the local settlers. He was needed and welcomed in the community but withal he was eyed with some skepticism and was greeted with greater familiarity than he could at first enjoy; the title "Doc" had no virtue in his ears. Until then the community either had accepted the uncertain services of the local incumbents (one qualified but inactive, one a bluff army surgeon of sketchy training), or sent when in real need for one of the established physicians of Rochester, fifteen miles away. The new "doc" had not an easy role.

Dr. William W. Mayo, of Rochester, proved to be a kind and helpful friend who initiated the young physician into country practice and on occasion so maneuvered as to concentrate attention on the boy's professional ability, in a generous spirit that Dr. Fairchild never forgot. At the older man's suggestion he joined the Olmsted County Medical Society, attending the meetings in Rochester when roads and practice permitted: "The most important events so far as my memory goes were the occasional invitations to dinner at Dr. Mayo's home, where I saw W. J. and C. H. running about in short pants." These brothers in their adult years were among his closest friends to the end of his life. In June, 1871, at Minneapolis, Dr. Fairchild became a member of the Minnesota State Medical Society, and he was present at three other meetings semi-annual and annual, within the next year. From those sessions he recalled with affection many men whose names are known throughout the state, from the Twin Cities and from various southern counties; here are mentioned only men from Olmsted County, Drs. Edwin C. and Elisha W. Cross, Dr. Hector Galloway, and Dr. W. W. Mayo, all of Rochester.

In those years "there was no science of medicine." Dr. Fairchild possessed a few established works, he later said, on the practice of medicine, on materia medica and therapeutics and obstetrics, which he read more or less secretly, "for it was believed by many people that a doctor must know all about medicine from experience and natural gifts in understanding of the mysteries of disease." Because he felt the need of further knowledge he joined medical socities and subscribed to the best medical journals available.

At High Forest on May 1, 1870, David S. Fairchild was married to Wilhelmina C. Tattersall of that village, a daughter of Captain William K. Tattersall, one of Olmsted County's earliest and most notable citizens. William K. Tattersall (1814-1893), a native of England, when an infant came to New York State with his parents; in 1856 he traveled to Minnesota and settled in High Forest and in that year built the Tattersall House, which for decades was to be a famed hostelry (the building was razed in 1946). He was a Civil War veteran, civic officer, postmaster, and member of the Minnesota legislature.

In 1872, after a little more than three years, Dr. Fairchild had become well established in the confidence, liking and respect of the community and of the profession of county and state. He had his own drugstore and he took part in civic affairs; in June, 1872, he served as grand juror from the county to the United States Circuit Court at Saint Paul. But he realized, and his wife concurred, that High Forest, past its zenith and without likelihood of gaining a railroad, held no future for a professional man, and he cast about for a new location. At this time Dr. Albert Richmond, of Ames, Iowa, a college classmate of Dr. Fairchild at Ann Arbor, was returning to his early home in Rochester, Vermont, and he wrote urging Dr. Fairchild to settle in Ames, to succeed him in practice. So it was that on July 10, 1872, Dr. and Mrs. Fairchild with their infant son, David S. Fairchild, Jr., started with a horse and buggy for Ames. The story of that eventful trip is well told in Dr. Fairchild's memoirs. The story of his subsequent life and work is well known and is recorded in the annals of medicine in Iowa.

When Dr. David S. Fairchild died in Clinton, Iowa, on March 22, 1930, from thrombosis, he was survived by his wife, Wilhelmina Tattersall Fairchild, by their son Dr. David S. Fairchild, Jr., of New York City, and two daughters, Margaret Fairchild Reynolds, wife of Dr. H. R. Reynolds, of Battle Creek, Michigan, and Gertrude Fairchild Brown, wife of A. W. Brown, of Davenport, Iowa, and Tucson, Arizona. Mrs. Fairchild died in Clinton on April 23, 1943, at the age of ninety-two years. Earlier, on November 18, 1940, Dr. D. S. Fairchild, Jr., died in an automobile accident, at the age of sixty-nine years. A colonel in the United States Army Medical Reserve Corps, he had been recalled to service and was on his way to Washington, D. C., when the accident happened; his service during World War I, as chief surgeon to the famed Rainboy Division, is a matter of record. In 1945 David S. Fairchild, III, son of Colonel Fairchild, was with the United States Army in Germany; Mrs. Reynolds and Mrs. Brown were in their former places of residence. A grandson of Mr. and Mrs. Brown is David Fairchild IV Salter.

(To be continued in the September issue.)

President's Letter

POSTPONED HEALTH PROBLEMS

Postponement of health needs is one of the most dangerous and deeply rooted problems confronting the medical profession today.

Patients defer a visit to the family doctor because they're "sure to feel better tomorrow"; and the price they pay, in suffering and extended convalescences, doesn't seem to change this practice of procrastination.

The same habit, with one variation, applies to the children of these "wait-and-see" patients. The exception is that medical supervision of infants has become an accustomed rule—Minnesota's outstanding record of maternal and infant health bears out this truth here—but after the child is old enough to walk, he apparently is considered safely on his way to maturity. The regular health check-up is forgotten; the youngster is given medical attention only when he is clearly and unmistakably ill.

The lapse in medical supervision between the ages of two and five or two and six is still a critical problem; but its consequences have been mitigated by the annual summer round-up. Through this school health program, the diagnostic tools of medical science operate with speed and assurance to help junior citizens reach and enjoy healthy maturity.

Useful by-products of the round-up include the children's recognition of the necessity for good nutrition, adequate rest and clothing, cleanliness and regular check-ups. They gain valuable knowledge of body mechanism and, often most important of all, they learn to accept the physician as a friend, someone whose help is to be welcomed, not feared.

If the school health program is beginning now in your community, it deserves your co-operation. If your locality hasn't developed a round-up plan for health examinations, why not help to organize one?

J. J. Elias.

President, Minnesota State Medical Association

REGULATION OF DRUGS AND MATERIALS USED IN THE HOME

WE NOTE that our Senator Humphrey has submitted a bill to the Senate (S 3852) permitting oral authorization for the dispensing and refilling of certain prescriptions, providing a written prescription is supplied later. At present, it is illegal for a druggist to fill a first prescription for a narcotic or barbiturate without having the written prescription in his hands. What is also irritating to the physician and, doubtless, more so to the druggist is that while a prescription containing a barbiturate can be refilled by the druggist upon verbal authority from the physician over the telephone, this is not allowed for refills containing a narcotic. A written prescription must be in the hands of the druggist before he can dispense an original or a refill of a narcotic prescription.

As a result of such a stringent regulation, which is so often impractical to observe, the law is broken right and left. Imagine a dentist called by telephone after office hours for relief of a toothache. In order to provide a remedy containing a narcotic, some arrangement has to be made to transport a written prescription from the dentist to the druggist before the druggist is allowed legally to dispense the drug. A physician is called upon during the day or, as so often happens, in the evening to supply a cough syrup which, in his opinion, should contain more than the maximum grain to the ounce allowed without the narcotic prescription. The mechanism of supplying the druggist with a written prescription before the patient obtains the remedy, as provided by regulation, is most cumbersome and irritating to everyone concerned.

Admittedly stringent regulations of habit-forming drugs, such as the opiates and barbiturates, are necessary. Their use, particularly the use of the barbiturates with suicidal intent, has become so common as to constitute a problem. Perhaps one-seventh to one-fifth of suicides are due to barbiturates. These are not the only drugs, however, which may be lethal when taken in overdosage. A drug dispensed by written prescription is just as lethal as one authorized by telephone pending the mailing of the prescription. Because a druggist has been occasionally duped by a drug addict impersonating a physician over the telephone scarcely justifies this stringent regulation, the full observance of which seems unreasonable to expect. Although we agree, one hundred per cent, that regulation of drug traffic is necessary, laws however strict cannot wholly prevent the intentional overdosage of certain drugs with suicidal intent.

When it comes to accidental poisoning, particularly of young children who help themselves to pills and solutions found within and without the medicine cabinet, the list is long. It is surprising to note that not so many years ago strychnine poisoning constituted about half of the fatal poisonings in children under five.* The Aloin Strychnine and Belladonna pill and the Hinkle pill were largely to blame. The 1946 National Formulary has eliminated the strychnine from the Hinkle pill but has doubled the strychnine (from 1/120 to 1/60 grain) in the A.S. and B. pill. The ingestion of ten to fifteen of these by a small child might well prove fatal.

The physicians, called upon to advise the parents when a child has ingested one of the many household materials which may or may not be poisonous, is frequently in a quandry whether there is need for treatment or not. As suggested by Gold,* something should be done to insure that the label on the container contains the name and amount of chemical present in the preparation. A lot of unnecessary treatment might then be obviated. Here is an opportunity for some constructive legislation.

We mention the obvious conclusion that unused and poisonous drugs be discarded or at least be kept in a place inaccessible to children.

---

ADVERTISING PROGRAM

At a combined meeting of the Board of Trustees and the Campaign Co-ordinating Committee of the AMA held on May 28, 1950, it was decided to undertake a nationwide advertising program in October. Emphasis is to be made on the importance of voluntary health insurance—not of any special type but the kind that fits the individual case—in contradistinction to compulsory state-provided and tax-supported medical care. It was at first thought impractical to use the usual media of advertising, such as newspapers, magazines and radio but this is exactly what will be used this fall in a concentrated educational drive. The total advertising budget of $1,110,000 will be allocated, $560,000 to some 11,000 daily and weekly newspapers throughout the country, $300,000 to radio, and $250,000 to about thirty national magazines. The medical profession may have been slow in taking up the challenge to their very existence as a private enterprise but if the wave of socialism which has spread over the country is stemmed and private industry saved, the medical profession will deserve much credit.

The medical profession would welcome a showdown vote in Congress on the proposal to nationalize the profession in order to clear the atmosphere and settle the question whether the people of this country wish this change. Until such time as the issue is settled, our efforts which so far have been successful beyond expectation will have to be continued to assure the existence of medical care as a private enterprise.

The AMA requires the support of every physician in the country. Have you done your part financially by sending your check, made payable to the AMA for $25.00, to the Minnesota State Medical Association office at 496 Lowry Medical Arts Building, Saint Paul? Last year the percentage of our state members who paid the voluntary assessment of $25.00 for this same purpose was nothing to be proud of.

This advertising program is entirely educational in nature, though it will be called by other names by our opponents. Financial support to the extent of $25.00 is the least each member can do in defense of his practice. Just as important is the personal education he carries out on his patients and friends in his everyday contacts.

Since the above was written, our attention has been called to the address* of our national president, Dr. Ernest E. Irons, before the AMA House of Delegates at San Francisco on June 26, 1950. The address deals with the modern trend towards a nationalistic government and should be read by every member.

SHOE-FITTNG FLUOROSCOPES

We ARE ADDING our voice to those raised elsewhere† in issuing a warning of the possible danger from the indiscriminate use of the fluoroscope for fitting shoes. All such apparatuses are not of equal strength, are not built with the x-ray tube at the same distance from the foot, and are not regulated for the same period of exposure.

It is perhaps not generally appreciated that repeated exposures from such innocent machines can affect the growth of bones in the feet of children, especially by their action on the epiphyses of the bones of the feet, to stunt their growth without showing evidence of affecting the skin—in other words, from less than an erythema dose. Repeated exposures may cause skin lesions at a later date without evidence of deleterious effect while the exposures are being received.

Most machines provide sufficient protection to the shoe clerk. The chief danger lies in the repeated exposure of the foot and particularly that of a child. They are not playthings for children or adults and should be kept under lock and key and be used only under the direction of an attendant who knows the possible dangers from overexposure to the x-rays.

Although no reports have appeared of untoward or severe injury having been caused by these shoe-fitting x-ray machines during the past two decades during which they have been used, warnings were issued some ten years ago by the New York Roentgen Society, in the *Monthly News Letter* of the American College of Radiology in February, 1948, and again in March, 1950, also in an editorial sponsored by the College in the *Journal of the American Medical Association* of April 9, 1949.

---

*J.A.M.A. 143:977-979 (July 15) 1950.

†Hemplemann, L. H.: Potential dangers in the uncontrolled use of shoe-fitting fluoroscopes. New England J. Med., 241:335, (Sept. 1) 1949.

Williams, Charles R.: Radiation exposures from the use of shoe-fitting fluoroscopes. New England J. Med., 241:333, (Sept. 1) 1949.

As a result, regulations have been made regarding the use of these machines in certain cities. The New York City Health Department has specified that the maximum permissible dose per exposure shall not exceed two roentgens as far as the machine is concerned, and that not more than three exposures in one day or twelve in one year shall be allowed. An easily readable sign to this effect is required to be posted on the machine. The New York City Sanitary Code makes further specifications for the protection of the operators and attendants.

AMA MEETING

SOME 10,119 physicians registered at the annual meeting of the American Medical Association in San Francisco, June 26-30, 1950. Of this number, 5,517 were from California, 455 from Illinois, 311 from New York, and 154 from Minnesota. The attendance compares favorably with the second largest registration of 13,221 at Atlantic City last year and the largest registration in history, that at Atlantic City in 1947, the Centennial meeting of the Association, when 15,667 physicians registered.

Continuation of the National Education Campaign during 1951 with the firm of Whittaker and Baxter as directors was approved. In 1951, a subscription to *The AMA Journal* will be included in the dues of $25.00.

The following officers were elected by the House of Delegates:

John W. Cline, San Francisco, President-Elect

R. B. Robins, Camden, Arkansas, Vice President

George F. Lull, Chicago, Secretary (re-elected)

J. J. Moore, Chicago, Treasurer (re-elected)

F. F. Borzell, Philadelphia, Speaker of the House of Delegates (re-elected)

James R. Reuling, Bayside, New York, Vice Speaker (re-elected)

Leonard Larson, Bismarck, N. D., Trustee

Thomas P. Murdock, Meriden, Conn., Trustee.

Doctors like fees no doubt—ought to like them; yet if they are brave and well-educated, the entire object of their lives is not fees. They, on the whole, desire to cure the sick; and if they are good doctors, and the choice were fairly put to them, would rather cure their patient and lose their fee than kill him and get it.—JOHN RUSKIN.

SUGGESTIONS FOR THE DIAGNOSTIC STUDY OF A PATIENT WITH AN ABNORMAL X-RAY SHADOW OF THE CHEST

The mass chest x-ray surveys have increased the number of patients consulting physicians about chest diseases. In these survey films, as well as in other chest films taken routinely, abnormal shadows may be found. The roentgenologist reports these shadows as he sees them and he then interprets the findings in the light of his past experience. It must be emphasized that the roentgenologist is not able to give either a bacteriological or histological diagnosis from the x-ray film. He can, however, give very accurate diagnosis in many of the films that he reads. The absolute diagnosis, however, still remains the responsibility of the clinician. The following suggestions are made to aid the physician in making a diagnosis of chest lesions. It is apparent that these suggestions are minimal in character and that the physician may and can add to them.

1. What constitutes the clinical history in a case of chest disease? The history should be detailed and in the patient's own words. In addition leading questions should bring out in particular—

(a) What diseases are endemic in the patient's locality?

(b) Has the patient been exposed to tuberculosis and if so, when, where, and to what extent? Has there been a family history of tuberculosis and was the patient exposed to the members of his family who suffered from the disease?

(c) The occupational history should emphasize the possible exposure to irritating dusts, vapors, et cetera.

(d) Was it possible for the patient to have been exposed to fungi or has the patient resided in or traveled through known endemic areas?

(e) What is the racial extraction of the patient? It is well known that certain races are more prone to tuberculosis than are other races.

(f) Has the patient ever had a chest x-ray before? If so, for what purpose, and can it be obtained for comparison purposes?

(g) Has the patient ever had a tuberculin test? What was the result?

(h) Has the patient ever had any previous chest diseases?

2. What constitutes the physical examination?

The physical examination should be made with the patient completely disrobed and in a well-illuminated room. It should include the examination of all organs and systems in the body and every orifice should be examined.

3. What is the minimum amount of laboratory work indicated?

It is suggested that the minimum amount of laboratory work should be—

(a) Hemoglobin

(b) White blood count

(c) Sedimentation rate

Report of the Committee on Tuberculosis, Minnesota State Medical Association.

(d) Urinalysis
(e) Wassermann test
(f) Agglutination test for undulant fever

Other laboratory procedures should be ordered when indicated.

4. What is the role of the tuberculin test (Mantoux test)?

This is the most valuable test known to determine existence of an infection by tuberculosis. The test for accuracy is dependent upon—

(a) Potent material
(b) Proper intradermal injection
(c) Proper interpretation of the test at the end of 48 to 72 hours.

The test should be read then by the degree of induration and not by the zone of erythema. For practical purposes it is not necessary to give the degree of reaction but rather to report the test as either positive or negative. Any induration exceeding 5x5 mm. is considered a positive reaction. *The tuberculin material in Minnesota is supplied free of charge by the Minnesota State Board of Health. The committee would like to emphasize that every patient consulting the physician for any purpose whatsoever, should have a routine Mantoux test.* Should the test prove positive, the patient should have a chest x-ray and this should be repeated once yearly if no active disease is found on the original film. Those people who have a negative Mantoux reaction should be retested not less than once yearly. The committee also suggests that the patch test not be used. When indicated, other skin tests may be applied. A positive Mantoux test does not mean clinical tuberculosis.

5. What is the role of the roentgenologist?

The roentgenologist has an important role in the screening of chest x-ray films. In making his report he should not be too positive in his diagnosis but rather describe the lesions seen and then suggest the possible diagnosis. When indicated, the roentgenologist should feel at liberty to suggest other specialized x-ray procedures to help in making the diagnosis. Wherever possible, both he and the clinician should determine whether other chest x-ray films have previously been made on the patient in question, and if so, an effort should be made to obtain the films for comparison. It must be emphasized that serial x-ray films of the chest are often more valuable than a single film. Follow-up x-ray films should be made on every patient who has a chest lesion and/or who has a positive Mantoux test. The maximum period between films should not exceed one year. X-ray films should always be required at the time of discharge of patients from the hospital after apparent recovery from acute chest diseases. *Most important, make use of the roentgenologist as your consultant.*

6. What is the minimal laboratory work indicated to determine the presence of the tubercle bacillus?

It is necessary to know that the material being submitted for examination actually has come from the lungs and that it is not simply saliva or nasal discharge. The committee suggests that three successive 24 hour sputum specimens be submitted for smears, culture and/or guinea pig inoculation. If the attending physician suspects that other organisms than the tubercle bacillus are causing the chest lesion, he should so inform the laboratory personnel. When the patient is not raising sputum, gastric washes should be done and the material submitted for both guinea pig and/or cultural investigation. The gastric washes may be obtained—

(a) As a result of an over-night stay in the local hospital
(b) In the local tuberculosis sanatorium after the proper arrangements have been made with the medical director
(c) In the physician's office
(d) In the patient's home with the help and assistance of the local public health nurse.

It is essential that exact technique be used in obtaining of the material. The information concerning the technique may be obtained either from the local sanatorium or from the State Health laboratories. Exudates, such as pleural fluid, et cetera should also be submitted for laboratory investigation. Do not overlook the possibility of finding malignant cells in sputum, exudates, et cetera.

7. What should be the follow-up care of the tuberculosis patient recently discharged from the sanatorium?

The committee suggests that the private physician consult the sanatorium director for detailed information concerning the patient's sanatorium course and what suggestions the medical director may give for the follow-up care of the patient. Here again, it is important to remember that the sanatorium medical director is your consultant; make use of him in the management of the sanatorium's discharged patient.

8. How shall the patients with indetermined chest lesions be classified?

If the patient has been thoroughly studied, the committee feels that the attending physician's classification should be accepted for the record. The diagnosis ot tuberculosis remains a presumptive or suspected diagnosis until the tubercle bacillus has been demonstrated. If a positive diagnosis has been made, have you reported the case to the Health Department?

9. What other procedures may be used to diagnose chest lesions?

There are a great many highly specialized investigations that assist in making the diagnosis of a chest lesion. Some of these, such as bronchoscopy, bronchograms, kymography, and the like, can only be done in centers especially equipped for such studies. When these specialized studies are indicated, the attending physician should refer his patient to a physician or to an institution equipped to carry out such investigations.

10. What should be the follow-up procedure in the patient in whom chest lesions have been found?

The committee recommends that the private physician make every effort to see that such patients be reexamined periodically. It is the duty of the private physician to use every facility at his command to have his patients return for chest and x-ray examinations. Whenever necessary, he should call upon the public health nurse in his locality or the public health officer to aid him in the periodic follow-up of the patient with a chest disease.

BCG VACCINATION

Considerable attention has recently been given to BCG vaccination in the public press. From this publicity the impression might be gained that this procedure alone holds promise of real control of tuberculosis. Since such an impression might postpone indefinitely the establishment and extension of accepted control measures, this statement of the status of vaccination in tuberculosis control programs is issued.

1. Control measures in tuberculosis should be directed at eradication of the disease as a major cause of death or disability.

2. The marked improvement in tuberculosis mortality figures, particularly for the ages under thirty, demonstrates the effectiveness of the present control program.

3. The low rate in children and the continuing high rates in adults over fifty emphasize the location of the problem at the older age levels rather than in children. Under these circumstances, the efficiency of a method of tuberculosis control would be measured by its effect on the mortality from tuberculosis in the older age group, rather than in children.

4. The addition of a vaccine to the present control program requires both careful and adequate consideration. Of the vaccines proposed, BCG has been used most widely and is the one most often discussed.

5. This has been used for more than twenty-five years and recently many millions of people have been vaccinated. However, it must be stated that there is no evidence that meets strict scientific requirements demonstrating that BCG effects the control of tuberculosis, despite the very suggestive results of a few studies.

6. Because of the above fact and because there is no general agreement among investigators anywhere in the world on such fundamental matters as the preparation of vaccine, the method of vaccination, what constitutes a successful vaccination, how resulting immunity may be measured, how long such immunity lasts, et cetera, the procedure would seem to be still in the investigational period.

7. It is therefore recommended that investigation of vaccination in tuberculosis be continued and increased under standard and stringently controlled conditions. This investigation should be designed to determine if the vaccine is indeed effective and what the limitations of its use may be. It would seem desirable that in each country, one agency, preferably the official health agency, should have control of the investigation.

8. Until this has been determined and until these controlled studies are completed, the use of BCG vaccine should be limited to such investigative studies.

9. At the present time the methods which have been proved effective in tuberculosis control should be increasingly applied to all segments of the population, regardless of decreasing mortality figures, so long as tuberculosis remains an important cause of death. These measures include mass x-ray case finding, early diagnosis, rapid institution of treatment, isolation of open cases, and the restoration of the patient to normal life.

Report of the Council on the Management and Treatment of Diseases of the Chest, American College of Chest Physicians.

WHO IS HARDEST HIT?

Doctors should be aware of the fact that the families under their care who earn under $5,000 a year pay most of the tax bills. Family physicians in many instances could bring this realization to those in that bracket whom they attend. Curiously, many people do not comprehend this simple truth. Why do these families pay most of the tax bills? Because there are so many of them. The Federal Reserve reports that 8,250,000 families receive more than $5,000 a year, that 29,250,000 families get less.

But these 29,250,000 families pay most of the taxes because they consume the most products. For products pay taxes! There is a hidden tax on every product that moves from mine or farm or forest or fishery, or from factory to wholesaler, from wholesaler to retailer, from retailer to consumer—and transportation taxes every time the product moves. By sheer force of numbers, the smaller income group pays most of these taxes.

The 38 per cent of net income that a corporation is taxed is paid by consumers who buy the corporation's products. Families with incomes of less than $5,000 buy 72 per cent of the nation's automobiles, wear most of the clothes sold, use most of the electricity, and eat most of the food. Every time they buy a new automobile, the $400 which taxes represent give them less automobile and more tax burden than they think. They smoke 70 per cent of all tobacco; about 50 per cent of what they pay for tobacco and gasoline is in taxes.

Families of under $5,000 income bought 64 per cent of the food in Denver, 69 per cent in Detroit, and 71 per cent in Houston, according to a Labor Department study of these typical cities. Of course, they must have paid about that proportion of corporation taxes levied on food companies in those cities. What is true of these products holds true for almost all family consumption. And since taxes can be paid only out of products, it is the total family spending of these 29,250,000 families that pays the bulk of our taxes.

* * *

Many young physicians and their families are in this income bracket as they start out. Do they realize what deficit spending is doing to them? Would it not be well to think about that? Especially in view of coming Congressional and Presidential elections.

* * *

No matter what party achieves power, the principle holds good that deficit spending and high taxation bear most heavily on those who can least afford these luxuries, until finally ruin brings despair to all alike. Editorial Comment—New York State Journal of Medicine, August 15, 1950.

MEDICAL ECONOMICS

Edited by the Committee on Medical Economics
of the
Minnesota State Medical Association
George Earl, M.D., Chairman

GRADUATES WARNED OF DEFICIT SPENDING

The *Wall Street Journal* recently gave graduates a commencement address on the evils of deficit spending—a subject all Americans could study with grave concern. The *Journal* says:

> "No one could blame these young people, then, if they were to regard Treasury deficits as a normal way of life. Some folks much older seem to regard red ink in the budget as nothing to worry about. A few even contend that through deficits lies the road to prosperity. And a handful have argued that a huge Government debt is no cause for concern—after all, 'we owe it to ourselves.'"

Showing the fallacy of these ideas, the *Journal* quoted the campaign speech of Franklin D. Roosevelt:

> "If a nation is living within its income, its credit is good. If in some crisis it lives beyond its income for a year or two, it can usually borrow temporarily on reasonable terms. But if, like the spendthrift, it throws discretion to the winds, is willing to make no sacrifice at all in spending, extends its taxing up to the limit of the people's power to pay, and continues to pile up deficits, it is on the road to bankruptcy."

The editorial then described what the giver of such good advice did about it, revealing that in every year since Roosevelt's election, there was a mounting government deficit. The debt has not stopped climbing during this present administration—in fact, it is bigger than ever. The *Journal* has this to say:

> "There is in the Administration at Washington no real will to save—to trim unnecessary expenditures, to forego housing subsidies and farmer subsidies and bigger welfare programs. Yet the fiscal figures show the Government can't afford them.
>
> "There is no will to fiscal sanity at Washington because the Administration still follows the political advice of the late Harry Hopkins to tax and spend and elect. Whenever there is criticism of deficits then there is an excuse: why, we're fighting a cold war and we can't balance the budget because we must build our defenses and help Europe in the battle against Communism.
>
> "It's a good alibi but it's not the reason. A recent Senate committee study showed that a large part of the rise in expenditures the past couple of years has been due to strictly domestic projects. Farm price supporting and home mortgage financing are examples."

Another President Quoted

Giving sound advice, the *Journal* remarks that those college graduates will do well to recall the history they've been studying. They'll remember that no nation has ever succeeded in spending its way into permanent prosperity. "The deficit roads of past centuries are studded with collapsing nations." Concluding, the *Journal* reminds the graduates that it might be a good idea to throw this quotation of George Washington's at any candidate who thinks deficits are good:

> "As a very important source of strength and security, cherish public credit. One method of preserving it is to use it as sparingly as possible, avoiding occasions of expense by cultivating peace, but remembering, also, that timely disbursements, to prepare for danger, frequently prevent much greater disbursements to repel it; avoiding likewise the accumulation of debt, not only by shunning occasions of expense, but by vigorous exertions, in time of peace, to discharge the debts which unavoidable wars may have occasioned, not ungenerously throwing upon posterity the burden which we ourselves ought to bear."

Graduates might also note the words of Dwight D. Eisenhower:

> "Since government takes about one-fourth of every worker's income, and still can't make ends meet, he should have sense enough to insist that the government do what he himself has to do in the same circumstances —cut its spending by a like amount, at least."

POSTERITY STILL BEARS BURDEN

That same burden which concerned President Washington apparently has not been bothering those who control present-day government spending. Placing the burden squarely on the shoulders of taxpayers, the government still spends lavishly, the federal debt now amounting to about 278 billion dollars.

But, due to hundreds of hidden taxes paid daily, the average taxpayer has a difficult time knowing how much he actually pays the government in taxes. A recent pamphlet from the Minnesota Taxpayers Association has brought to light the enormous amount of hidden taxes paid on ordinary items:

> "But what about the hidden taxes—the taxes that build up all the way along from raw material to the finished goods on the shelves of retail stores?
>
> "There are 206 taxes levied during the manufacture and sale of that new Chevrolet and covered in the price you pay your dealer. Or, if you buy a new suit of clothes, you're paying 116 taxes. A new hat for your wife, 150 taxes. A loaf of bread, 151 taxes. And a dozen eggs, 100 taxes.
>
> "You'll probably be surprised to learn that these hidden taxes are costing you and your family some $700 this year—at least, that's the national average. Nine out of 10 families pay more in hidden taxes than they do in income tax."

Illustrating other hidden taxes, the pamphlet states that the smoker pays 11 cents taxes on every package of cigarets bought. Of this amount, 7 cents is federal, 4 cents is in state taxes. "If you smoke a pack a day, you're paying $40 a year tax. With more than half the selling price going for taxes, cigarets are among the most ruthless tax collectors the government has."

The Taxpayers Association has also discovered that Americans pay more annually to be governed than they pay for food. Combined cost of all government functions last year was 56 billion dollars. The national food bill came to 53 billion dollars—convincing enough figures to cause Americans to take an active interest in the amounts being spent by the people elected to represent them in Washington.

AMA PRESIDENT HITS STATE SOCIALISM ISSUE

Making his initial speech as president of the American Medical Association, Dr. Elmer L. Henderson called American medicine only the first socialization goal of "a comparatively small group of little men—little men whose lust for power is far out of proportion to their intellectual capacity, their spiritual understanding, their economic realism or their political honesty."

Government Medicine—A Step to Socialism

Dr. Henderson cited these little men for attempting to bring all fields of human endeavor under government control:

> "These men of little faith in the American people propose to place all our people—doctors and patients alike—under a shabby, Government-dictated system which they call 'Compulsory Health Insurance.' And this, factually, is Socialized Medicine, regardless of how hard they try to disclaim it.
>
> "But it is not just 'socialized medicine' which they seek; that is only their first goal.
>
> "Their real objective is to gain control over all fields of human endeavor. Their real objective is to strip the American people of self-determination and self-government and make this a Socialist State in the pathetic pattern of the socially and economically-bankrupt Nations of Europe which we, the American people, are seeking to rescue from poverty and oppression."

Dr. Henderson warned doctors throughout the nation that socialism differs from communism only in one particular. He said:

> "This we must all recognize:
>
> "There is only one essential difference between Socialism and Communism. Under State Socialism human liberty and human dignity die a little more slowly, but they die just as surely!"

INDUSTRY LEADERS SANCTION "RIGHTS OF FREE MEN"

Helping to sustain these human liberties and human dignities, some of the nation's leading industrial men, meeting recently in Boston, endorsed the following "rights of free men" so that the individual American "may face the future with confidence":

> "1. The right to personal initiative; to choose freely; to lead but not to dictate; to follow but not to be driven.
>
> "2. The right to opportunity; to have a chance to forge ahead by his own efforts; to succeed or fail; and if he fails to try again.
>
> "3. The right to personal dignity; to be protected from those impositions of others which they would not impose on themselves.
>
> "4. The right to participate in affairs of common concern; to hear and be heard; to stand alone or to be one among equals.
>
> "5. The right to provide for the future; to save or to spend; to advance or hold still; to be judge of his own welfare."

THE INTERURBAN ACADEMY OF MEDICINE

INVITES YOU TO ATTEND A

CANCER TEACHING CLINIC

Duluth, Minnesota **October 18, 1950**

Clinic Sponsored by the

Minnesota State Medical Association
Minnesota Division, American Cancer Society
Minnesota Department of Health
Wisconsin State Medical Society
Wisconsin Division, American Cancer Society
Wisconsin State Board of Health

No Registration Fee—Program furnished through funds of the American Cancer Society and its Minnesota and Wisconsin Divisions.

Afternoon Session—Saint Mary's Hospital, Duluth

P.M.
2:00 Motion picture—"Breast Cancer—The Problem of Early Diagnosis."
2:30 "Cytological Diagnosis of Malignancies"
John R. McDonald, M.D., Associate Professor of Pathology, University of Minnesota Graduate School, Minneapolis-Rochester, Minnesota.
3:10 Recess
3:20 "Office Diagnosis of Malignancies"
Carl W. Eberbach, M.D., Associate Clinical Professor of Surgery, Marquette University School of Medicine, Milwaukee.
4:00 "The Problem of Carcinoma of the Lung"
Richard L. Varco, M.D., Associate Professor of Surgery, University of Minnesota Medical School, Minneapolis.
4:40 General symposium and question and answer period.

Evening Session—Gitchie Gammi Club, Duluth

P.M.
5:30 Social hour
6:30 Dinner
"Radical Surgery in Advanced Cancer of the Female Genital Tract"
Alexander Brunschwig, M.D., Professor of Clinical Surgery, Cornell University Medical College, New York.

Minnesota Academy of Medicine

Meeting of March 8, 1950

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, March 8, 1950. Dinner was served at 7 o'clock, and the meeting was called to order at 8:10 p.m. by the President, Dr. William A. Hanson.

There were forty members and two visitors present.

Dr. Hanson announced the election of new members for the April meeting. Dr. Lepak announced that recommended changes in the Constitution and By-Laws of the Academy would go out with the program of the April meeting, to be voted on at a later date.

Dr. J. K. Anderson introduced Dr. Vernon Waite, of Honolulu, who gave a short talk. Dr. Burch then presented Dr. Donald Hastings of the University of Minnesota Medical School.

Dr. Ritchie requested that proposals for new members be sent in very soon so that they could be considered by the Executive Committee before the April meeting.

The scientific program followed.

Dr. Harold Diehl, of the University of Minnesota, gave a report on his recent trip to Britain, entitled "Medical Education in Britain," after which he answered several questions by the members present.

The meeting was adjourned.

WALLACE P. RITCHIE, M.D., *Secretary*

Meeting of April 12, 1950

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, April 12, 1950. Dinner was served at 7 o'clock, and the meeting was called to order at 8 p.m. by the President, Dr. William A. Hanson.

There were sixty members and four guests present.

The President announced that Dr. Donald MacKinnon had been elected to active membership in the Academy and the secretary was instructed to notify Dr. MacKinnon of his election.

The President appointed a Memorial Committee to draw up a Memorial to Dr. James K. Anderson, to be presented at the May meeting.

Upon ballot, the following were elected as candidates for membership in the Academy:

Minneapolis	Dr. E. T. Evans
Minneapolis	Dr. Thomas Lowry
St. Paul	Dr. Harold Flanagan
University	Dr. Donald Hastings

The scientific program followed.

CURRENT MORTALITY OF TRANSURETHRAL RESECTIONS

DONALD CREEVY, M.D.

Dr. Creevy, of the University of Minnesota, gave a paper on the above subject. Lantern slides were shown.

Abstract

Free hemoglobin, formed in the bladder when blood and water mix during transurethral resection, may be driven into the open prostatic veins and lead to a hemoglobinuria (lower nephron) nephrosis which may be fatal. This is particularly likely to occur if the kidneys have been damaged previously, or if renal vasospasm is produced during operation by excessive loss of blood, by prolonged hypotension, or by bacteremia, which has been shown to occur in 45 per cent of transurethral resections.

Hemoglobinuric nephrosis during transurethral resection can be prevented by using an isotonic, nonhemolytic irrigating fluid such as 4 per cent glucose, 1.1 per cent glycine, or 3 per cent mannitol.

In transurethral resection in one thousand consecutive cases done with the aid of isotonic solutions, Creevy, Webb and Smith have had a hospital mortality of 0.6 of 1 per cent.

Despite statements in the literature to the effect that, with modern use of antibiotics, transfusions, and anesthesia, the mortality of open enucleation of the prostate is now no greater than that of transurethral resection, the author found, in some 2400 retropubic, perineal, and suprapubic enucleations reported in the literature between 1945 and 1950 the average mortality was 5.3 per cent, or nearly nine times that of the author's series of 1000 cases, while the mortality of 3500 cases reported up to 1938 of open enucleation was 6.6 per cent. In contrast to this, Thompson has reported over 11,000 transurethral resections with a mortality of 1.5 per cent.

It seems reasonable to conclude that a well-done transurethral resection is a good deal safer than a well-done enucleation.

Discussion

DR. FREDERIC E. B. FOLEY (St. Paul): There is one most important thing for me to say about this excellent paper. I have known Dr. Creevy for a long time, he is honest, he tells the truth and if he tells you he has had an operative mortality of 0.61 per cent in 1000 cases of transurethral resection, you can depend on it that is just what he had.

Dr. Creevy's accomplishment and low mortality in these 1000 cases are remarkable.

The whole business of transurethral prostatic resection is remarkable. The enterprise began 20 years ago. At first there was wild enthusiasm. Then there was disillusionment. Now finally, among the enlightened, it is recognized as the operation of choice in a large proportion of cases. What that proportion will be in different hands does not depend on the "cases" so much as it depends upon the "doctor," and his honest appraisal of his own talent and ability as a resectionist.

More should be said—than Dr. Creevy said—about the effects of modern developments on the choice of operation for vesical neck obstruction. Mortality has dictated the choice, while morbidity and other undesirable accompaniments of extensive resections have been overlooked. Sulfa drugs, antibiotics, multiple transfusions and other improvements of modern surgery have made of suprapubic prostatectomy, perineal prostatectomy—and now retropubic prostatectomy—entirely different matters from what they were formerly. Through benefit of these improvements these operations nowadays—if properly applied and well performed—are just as safe as transurethral resection, will give a mortality no greater than Dr. Creevy reports for transurethral resection and will be accompanied by a hospital stay no longer than with transurethral resection. Besides that they are devoid of the morbidity, blood loss and other undesirable effects that go with "transurethral prostatectomy" in cases of very large prostates.

Transurethral resection in the hands of the casual resectionist will not give any such mortality as Dr. Creevy has had. The unfavorable morbidity and other bad effects will be even worse than the mortality. Transurethral resection is a highly specialized procedure and belongs only in the hands of the specialist. I confidently and sincerely believe that in other hands all patients with vesical neck obstruction will be better off with enucleation than with transurethral resection, even in the cases of small prostate not requiring large tissue removals.

If Dr. Creevy feels that his patients and he are better off taking out 80 to 100 grams by transurethral resection than they would be with enculeation it must be a good conclusion for him and has my approval.

A lot of people don't have that same conclusion about themselves. I for one do not. I can make a decent transurethral resection with removal of up to 50 grams of tissue and feel I have taken advantage of all the merit of the operation. When I go beyond that extent of tissue removal, all merit of the operation rapidly diminishes and with the very large prostates is completely lost.

The choice of operation is an individual matter for the surgeon and is conditioned by his skill and ability in the use of the different operations and the results he has had with them.

There is indeed such a thing as the status of a surgeon in the use of any operation. There is no such thing as the "present status" of any operation in the hands of thousands of different surgeons.

For me it works out this way: if it is a big gland—too big for a good resection in my hands—and he is a husky, good risk patient, I make a suprapubic prostatectomy. That operation is foolproof, always gives a good result and has no morbidity. If the big prostate is in a dilapidated old crock not fit for any operation I make a perineal prostatectomy. There may be some incontinence with perineal prostatectomy, in my hands, and other difficulties which affect more my vanity as an operator than the results obtained. But I know it is almost impossible to kill a patient by the operation. In cases of very large prostates in old poor risk patients I am glad to accept these disadvantages of the perineal operation rather than the greater morbidity of an extensive transurethral resection or the greater mortality of suprapubic prostatectomy.

With suprapubic prostatectomy as we do it now, the patient is out of bed, voiding normally and with a completely healed wound on the fourth to eighth day and usually is ready to leave the hospital by the tenth day.

At the meeting of the Southern Minnesota Medical Association recently we presented the results in the last previous 100 consecutive operations for vesical neck obstruction. There was one death. The difference between that and Dr. Creevy's mortality is .39 per cent, which is insignificant.

All in all, I think the functional result and morbidity is better with suprapubic prostatectomy than it is with transurethral resection.

Dr Philip F. Donohue (St. Paul): I wish to congratulate Dr. Creevy on his fine report. The remarkably low mortality in his large series is a tribute to the care in the selection and preparation of patients for operation and to the skill of the resectionists. Certainly such a record could scarcely be equaled by the occasional and unskilled operator. This highly specialized procedure carries with it the possibility of technical mishaps which will probably occur more frequently in inexperienced hands. But, even under the best of care and performance, some deaths will occur. The great difficulty is in the proper appraisal of operability. This is particularly true of cases in the cardiovascular group where it may be impossible to foresee the sudden collapse that occasionally occurs in the immediate postoperative period. But the risk must be taken when there is a real need for surgical relief.

Dr. Creevy (in closing): I want to thank the discussants for their kind remarks. Obviously, one could go on at great length about the details of prostatic surgery and about the advantages and disadvantages of the various operations when they are compared to one another. All I can say about transurethral resection is that one has to have an earnest desire to do a good job and to keep eternally at it just as the good golfer does. When the transurethral operation is well done, it is perfectly safe to say that it is safer, from the patient's point of view, than any of the open operations.

TREATMENT OF FRACTURES WITH THE INTRAMEDULLARY NAIL

WALLACE COLE, M.D.

Dr. Cole, of St. Paul, gave a paper on the above subject.

Discussion

Dr. Vernon L. Hart (Minneapolis): Dr. Cole has considered almost every phase of this fascinating subject of the intramedullary nail. I first became acquainted with this method of internal fixation when I was in the Army at Fitzsimons General Hospital in Denver, during 1944. I saw my first cases of the Kuntchner intramedullary nail in German prisoners of war who were brought to this country. They clean wounds, no serious complications, and free joint motions. We were impressed at that time because there at Fitzsimons General Hospital I was in charge of 187 patients who

MINNESOTA STATE MEDICAL ASSOCIATION
House of Delegates—Summary of Proceedings

Duluth Session—June 11-12, 1950

First Meeting, Sunday, June 11, 1950

The Ballroom, Hotel Duluth
Duluth, Minnesota

The Ninety-seventh Annual Session of the House of Delegates of the Minnesota State Medical Association was held in the Ballroom, Hotel Duluth, Duluth, Minnesota, beginning at 2 p.m., Dr. C. G. Sheppard, Hutchinson, Speaker, presiding.

Dr. Sheppard called the meeting to order. After approval of the minutes of the 1949 session, Dr. Sheppard introduced Dr. W. A. Wright, president of the North Dakota State Medical Association, who brought greetings from his state.

Dr. Sheppard then called for the report of Dr. O. J. Campbell, chairman of the Council.

Report of the Council

Dr. Campbell: The first meeting of the Council of the Minnesota State Medical Association was held on June 10, 1950, at 2 p.m. in the English Room of the Hotel Duluth, Duluth, Minnesota, for the transaction of routine business. The minutes of the previous meeting held on March 5, 1950 were approved . . . Your chairman will give a fairly detailed report of the Finance Committee later in the absence of Dr. Kennedy.

. . . the Council approved a resolution authorizing Dr. R. L. J. Kennedy, chairman, and the Finance Committee to dispose of the Nicollet Avenue Properties Corporation Bonds, if, after due consideration and proper advice, it was found to be advisable.

. . . the following applications for Temporary Affiliate Membership were approved: Arne D. Rydland, Crookston and William G. Atmore, Duluth.

. . . the following applications for Affiliate Membership were approved: Brand A. Leopard, Albert Lea; Ruth G. Nystrom, Malibu Beach, California, formerly of Minneapolis; Walter M. Boothby, Rochester; Arthur H. Sanford, Rochester; Frederick L. Smith, Rochester; John L. Crenshaw, Rochester; Della G. Drips, Rochester; Irving George Wiltrout, Oslo; John S. Grogan, Wadena; and Rufus O. Johnston, Hibbing.

Applications for Life Memberships were approved: Frank W. Calhoun, Albert Lea; J. Albert Schultz, Albert Lea; Arthur E. Benjamin, Minneapolis; Herbert B. Aitkens, Le Center; Herbert Z. Giffen, Rochester; Claude L. Haney, Duluth; Robert P. Pearsall, Virginia; and Moses L. Strathern, Gilbert.

Honorary Membership was granted to Myron M. Weaver, Vancouver, B. C., who is now Dean of the Medical School at the University of Vancouver, B. C.

The Council recommended that H. W. Leibold, Public Relations Director of the Minnesota Association of Chiropodists, be advised that, in any program involving general physical examinations of Ramsey County school children in which it is considered advisable to include the feet, the Minnesota State Medical Association would welcome the co-operation of the Association of Chiropodists, provided that such a program were under the supervision or direction of the orthopedic surgeons and that the entire survey had the approval of the Ramsey County Medical Society.

The Council voted to accept the reports of the Insurance Liaison Committee and the Committee on Medical Service.

The Council voted to recommend to the House of Delegates that Chapter One, Section Three of the By-Laws be revised to include the following stipulation in the second paragraph:

> "An active member who is delinquent in the payment of such dues for one year shall forfeit his active membership in the Minnesota State Medical Association if he fails to pay the delinquent dues within thirty days after notice of his delinquency has been mailed (by registered mail, return receipt requested) by the secretary of his component medical society."

The Council voted to request that the House of Delegates appoint a committee to study the advisability of establishing a special Minnesota State Medical Association membership classification for interns, to be known as an Intern or Junior Membership.

The Council voted to recommend the establishment of a permanent committee on Hospitals and Professional relations and a committee on Chronic Illness and Geriatrics.

The Council voted to contribute $100 to the National Society for Medical Research.

The Council recommended that members of the press be admitted to general sessions of the House of Delegates, reserving the right to call an Excutive Session.

The Council voted to recommend to the House of Delegates that it take cognizance of the honor bestowed on the medical profession by the selection of Dr. C. G. Sheppard, Hutchinson as the physician chosen by the *Ladies' Home Journal* for its "How America Lives" series. Also, it should be noted that Dr. Sheppard required some persuasion before he agreed to so represent the profession, and the Council wishes to express its appreciation to him and to his family for this co-operation.

Two resolutions were approved by the Council for recommendation to the House of Delegates:

1. A resolution reaffirming the association's well-considered and unhesitating opposition to socialistic infiltrations in any field of American thought and endeavor.

2. A resolution sanctioning and supporting the elimination of waste, duplication and inefficiency in the federal medical services of our country.

The Council voted to recommend to the House of Delegates that a resolution be drawn, instructing Minnesota delegates to the American Medical Association convention to support the Ohio State Medical Association's resolution for the establishment of a single membership classification in the American Medical Association.

Dr. Campbell then read the report of the Finance Committee which was approved by the Council. The report called attention to the fact that during 1949, there was an increase in net worth of the association of $4,126.45.

The House of Delegates approved the report of the Council, including the Financial Committee report, and Speaker Sheppard called for the report of the Reference

---

In accordance with action by the Council of the Minnesota State Medical Association in 1944, publication of the proceedings of the House of Delegates is limited to summary.

Committees. Dr. Sheppard called first upon Dr. L. E. Steiner, Albert Lea, Chairman of the Reference Committee on Medical Education Reports.

Medical Education Reports

Dr. Steiner: The Reference Committee for Medical Education Reports met in the Norse Room on June 11, 1950. The following Medical Education reports were considered:

Committee on Cancer—A. H. Wells, M.D., Duluth, Chairman.
Committee on Conservation of Hearing—L. R. Boies, M.D., Minneapolis, Chairman.
Committee on First Aid and Red Cross—John S. Lundy, M.D., Rochester, Chairman.
Heart Committee—F. J. Hirschboeck, M.D., Duluth, Chairman.
Committee on Hospitals and Medical Education—H. S. Diehl, M.D., Minneapolis, Chairman.
Committee on Public Health Nursing—Mario Fischer, M.D., Duluth, Chairman.
Committee on Syphilis and Social Diseases—Paul A. O'Leary, M.D., Rochester, Chairman.
Committee on Tuberculosis—J. A. Myers, M.D., Minneapolis, Chairman.
Committee on Vaccination and Immunization—Robert N. Barr, M.D., St. Paul, Chairman.

The Committee accepted these reports, together with the committee recommendations and comments: changing the term "free blood," as used in the report of the Committee on First Aid and Red Cross, to something more suitable; further inquiry into the adequacy of the reasons given by the Committee on Hospitals and Medical Education for the lengthening of the medical school year to ten months; approval of the statement that there should be some definite proposals given to doctors on immunization procedures to be followed to serve as a guide for instructors, nurses, etc.; discussion of the problem of caring for old syphilitic cases with the usual therapy of penicillin, and it was recommended that the House of Delegates adopt a proposal to have all practitioners check their positive blood patients with further examination by spinal fluid test to bring about a more efficient and complete record of these syphilitic patients.

The House of Delegates accepted the Report of the Reference Committee on Medical Education Reports as a whole with the Committee's recommendations.

Dr. Sheppard then called for the report of the Reference Committee on Miscellaneous Scientific Reports, Dr. R. F. Hedin, Red Wing, Chairman.

Miscellaneous Scientific Reports

Dr. Hedin: The Reference Committee for Miscellaneous Scientific Reports met in the Ballroom on June 11, 1950 and considered the following reports:

Committee on Anesthesiology—R. C. Adams, M.D., Rochester, Chairman.
Committee on Child Health—G. B. Logan, M.D., Rochester, Chairman.
Committee on Diabetes—J. R. Meade, M.D., St. Paul, Chairman.
Committee on Fractures—E. T. Evans, M.D., Minneapolis, Chairman.
Committee on General Practice—R. H. Creighton, M.D., Minneapolis, Chairman.
Historical Committee—Robert Rosenthal, M.D., St. Paul, Chairman.
Committee on Industrial Health—L. S. Arling, M.D., Minneapolis, Chairman.
Committee on Maternal Health—J. J. Swendson, M.D., St. Paul, Chairman.
Committee on Medical Testimony—E. M. Hammes, M.D., St. Paul, Chairman.
Committee on Military Affairs—J. H. Tillisch, M.D., Rochester, Chairman.
Committee on Nervous and Mental Diseases—W. P. Gardner, M.D., St. Paul, Chairman.
Committee on Ophthalmology—T. R. Fritsche, M.D., New Ulm, Chairman.
Committee on Public Health Education—A. E. Cardle, M.D., Minneapolis, Chairman.
Committee on Radio—R. M. Burns, M.D., St. Paul, Chairman.
Speakers' Bureau — Haddon M. Carryer, M.D., Rochester, Chairman.
Editorial Committee—C. B. Drake, M.D., St. Paul, Chairman.

The Committee approved the above reports, and recommends the following be added to the report of the Committee on Ophthalmology:

1. That it be considered unethical for any member of our association to accept fees or other remunerations in the form of rebates, refunds, or gratuities.
2. That publicity be given this policy, so that the public will be informed as to the policy of this association.
3. That any savings that may be incurred from the adoption of this new policy will be in favor of the patient.
4. That it be suggested that if any county medical society find a member violating this recommendation, he shall be subject to disciplinary action for infraction of the above.
5. That the Committee on Ophthalmology meet with various optical companies to standardize a policy regarding the dispensing of glasses.

The Committee recommends that efforts be continued along the lines of the Public Health Education Committee; that continued use of Speakers' Bureau, radio, advertising and literature distribution be encouraged.

The question of cost, particularly the advertising campaign, is a matter for definite consideration. The Committee finds that there has been inequitable distribution of cost, and recommends that this be rectified. The Committee suggests that the Council consider this matter in the year ahead.

The Committee recommends that the University of Minnesota attempt to gear post-graduate education to that of general practice; that, in an issue of Minnesota Medicine, the Committee on Maternal Health publish a routine satisfactory office procedure for RH testing; that the Committee on Medical Testimony continue to see to it that all medical testimony given in the courts continue on its present high plane.

The House of Delegates accepted the report with the exception of the reports of the Committees on General Practice, Maternal Health, Medical Testimony, Ophthalmology and Public Health Education, which were then discussed separately.

A manual on the establishment and operation of the Department of General Practice in hospitals was added to the report of the Committee on General Practice and accepted by the House.

The House accepted the recommendations of the committee regarding the report of the Committees on Ophthalmology, Maternal Health, Medical Testimony and Public Health Education.

Dr. Sheppard then called for Medical Economics Reports, Dr. H. E. Wilmot, Litchfield, Chairman.

Medical Economics Report

Dr. Wilmot: The Reference Committee for the Medical Economics Reports met in the Hotel Duluth, June 11, 1950. The committee considered the following reports:

Editing and Publishing Committee—E. M. Hammes, M.D., St. Paul, Chairman.
Committee on Interprofessional Relations—W. P. Gardner, M.D., St. Paul, Chairman.
Medical Advisory Committee—W. H. Hengstler, M.D., St. Paul, Chairman.
Committee on Medical Economics—George Earl, M.D., St. Paul, Chairman.
Committee on Medical Ethics—R. D. Mussey, M.D., Rochester, Chairman.
Committee on Public Policy—R. F. Erickson, M.D., Minneapolis, Chairman.
Committee on University Relations—E. M. Hammes, M.D., St. Paul, Chairman.

The committee accepted all the reports, with the following recommendations:

That an independent State Board of licensing practical nurses be recommended to the state legislature;

That, when issuing membership cards, the State association make some mention that the section which is to be sent to the Medical Advisory Committee in case of a malpractice suit does not mean that assistance is automatically forthcoming from the Medical Advisory Committee;

That the ads in the educational series be set off more distinctly in the newspapers.

The House accepted the report as a whole, referring the question of a state board on licensing practical nurses back to committee for consideration. Dr. Sheppard then called for the report of the Reference Committee on Miscellaneous Medical Economic Reports, Dr. L. E. Sjostrom, St. Peter, Chairman.

Miscellaneous Medical Economic Reports

Dr. Sjostrom: The Reference Committee for Miscellaneous Medical Economic Reports met in the Arrowhead Room on June 11, 1950 and considered the following reports:

Insurance Liaison Committee—A. W. Adson, M.D., Rochester, Chairman.
Committee on Medical Service—A. W. Adson, M.D., Rochester, Chairman.
Committee on Rural Medical Service—Paul C. Leck, M.D., Austin, Chairman.
Committee on State Health Relations—C. E. Proshek, M.D., Minneapolis, Chairman.
Committee on Veterans Medical Service—R. H. Creighton, M.D., Minneapolis, Chairman.
The Committee accepted all reports.

The report was accepted by the House and the Speaker called for the report of the Officers and Councilors, Dr. C. E. Rea, St. Paul, Chairman.

Officers' and Councilors' Reports

Dr. Rea: The Reference Committee for Officers and Councilors met on June 11, 1950, and the committee discussed the following reports:

Secretary's and Executive Secretary's Report, Councilor Reports from Districts One through Nine.

The committee wishes to commend the Medical Press Conference. The committee makes the following recommendation: That the designation of practical nurses be changed and the name "nurses' aide" be submitted for the term "practical nurse."

The House of Delegates accepted the report as a whole and referred its recommendation concerning practical nurses to the committee on Interprofessional Relations. The meeting adjourned at 5:30 p.m.

Second Meeting, Sunday, June 11, 1950

The Ballroom, Hotel Duluth
Duluth, Minnesota

The meeting of the House of Delegates of the Minnesota State Medical Association reconvened in the Ballroom of Hotel Duluth, Duluth, Minnesota at 8 p.m., Dr. Charles G. Sheppard, presiding.

The first order of business was a unanimous acceptance by the House of a 1949 recommendation of the Finance Committee that the $10 assessment, then in force, be continued for 1950, and, thereafter, dues be raised to $30 and the Constitution be thus amended.

The next item was a report from John Poor, substituting for Jarle Leirfallom, on the activities of the Division of Social Welfare. Mr. Poor reported that the number of people receiving old age assistance increased from 9,621 in 1946 to 14,256 in 1949. The total cost in 1949 was $4,973,000. Mr. Poor also explained the controversial Medical Estimate Form, the prior authorization form used by practitioners in estimating the amount of medical care needed by persons receiving old age assistance. The problem of the shortage of beds in rest homes and the shifting of the burden of caring for older folks, from their children to the county and state, were discussed by Mr. Poor, who recommended that doctors should not allow themselves to be talked into recommending rest home care unless the patient actually needs medical treatment. Mr. Poor stated:

> ". . . we are certain that in order to bring about a satisfactory medical program in public assistance, we, in public welfare, will require more and more cooperation from the medical profession. We can only achieve a successful program through the active participation of advisory committees made up of medical practitioners. We hope that our County Welfare organizations can come to the medical practitioners and ask for advice and help and they can get your cooperation in running their program locally. In an effort to control rising medical cost, we require follow-up checkups of recipients by the doctors attending these people. If the doctor indicates that the recipient no longer needs medical care, our County Welfare Board staff will be required to move these patients to other facilities as soon as possible.
>
> "For the staff of the Division of Social Welfare, I would like to convey our most sincere thanks to the medical profession of Minnesota for their interest and co-operation in helping us meet the problems of furnishing medical care to the aged of this state."

Supplementary remarks were made by Dr. F. F. Callahan, St. Paul, and Dr. A. W. Adson, Rochester.

Dr. Sheppard next called for a report on Minnesota Medical Service, which was given by Dr. McKinley. Dr. McKinley reported that Blue Shield, as of April, 1950, has an enrollment of 322,288. He said that "the success of the plan could not have been possible without the wholehearted support of the physicians of the state on the individual level, as well as on the organization level . . ."

Following this, the Speaker asked for a report of the Minnesota State Board of Medical Examiners by Dr. Julian Dubois. Dr. Dubois was not present, and the report was read by Dr. Magney, Duluth. Dr. Magney reported that during 1949 the Board licensed 320 doctors; the largest number ever to be licensed in a single year being 420 in 1947. The problem of licensing Displaced Persons to practice medicine in Minnesota has proved to be one which takes time and careful consideration. The Board of Medical Examiners, said Dr. Magney, wishes to continue to enlist the aid of members of the medical profession in this difficult job of processing applicants for the privilege of practicing medicine in this state.

Dr. Sheppard then called for the report of the Minnesota Department of Health, given by Dr. A. J. Chesley.

Dr. Chesley reported that during 1949, Minnesota had 73,000 live births. He said that the incidence of tuberculosis is decreasing and that deaths from the disease are also much lower. Dr. Chesley also stated that the nursing service is going on well.

Speaker Sheppard asked for the report of the Board of Basic Science, presented by Dr. Tregilgas who explained the work of the Board in reviewing applications for certificates.

Speaker Sheppard adjourned the House at 11 p.m. until June 12 at 12:15 p.m. for a luncheon, to be followed by the regular meeting at 1:30.

Third Meeting, Monday, June 12, 1950

The Ballroom, Hotel Duluth
Duluth, Minnesota

The House of Delegates reconvened at 1:30 p.m., Monday, June 12, 1950.

The first order of business was the final report of the Council by Dr. Campbell.

The Council voted to withhold approval of the Kellogg Plan, now proposed for Minnesota hospitals, until such time as the objectionable features were eliminated. The Council voted to refer to the Committee on First Aid and Red Cross a proposal to set up a separate committee on blood and its uses and the preparation of a brochure on blood use to be distributed to association members.

The Council considered a "Guide for Industrial Health Practice in Minnesota." Action on the Guide was tabled until the meeting on Tuesday, June 13, with the Minnesota Department of Health. Also, the Council referred to the Committee on Industrial Health the matter of investigating ways and means of effecting a waiver to that portion of the Workman's Compensation Law involving liability incurred in connection with employment of rehabilitated persons, thereby assisting the Department of Rehabilitation in the re-employment of such persons.

The Council accepted the recommendation of the Committee on State Health Relations that the county medical societies be urged to ask members of their societies to run for the office of coroner, as an act of public service, as this position was often found to be held by unqualified persons.

Also included in the final report of the Council were these recommendations: Dr. J. Arnold Bargen of Rochester re-elected as a Delegate to the American Medical Association; Dr. R. H. Creighton, to succeed Dr. J. C. Hultkrans as an Alternate Delegate to the American Medical Association, taking office in January, 1951; Dr. F. J. Elias to succeed Dr. W. A. Coventry as a Delegate to the American Medical Association; Dr. W. L. Burnap re-elected as an Alternate Delegate to the American Medical Association.

The Council voted to endorse and support the program of the Minnesota State Nutrition Council for the enrichment of flour and breads.

The Council recommended approval of a printed guide, "Medical and Dental Practices for Schools," contingent on approval by the Committee on Child Health.

The Council recommended that Mr. Rosell contact Dr. H. M. Carryer to discuss the invitation of the Olmsted-Houston-Fillmore-Dodge County Medical Society to hold the 1951 convention in Rochester.

The Council voted to convey to the State Health Relations Committee its approval of their recommendations that consideration be given to suitable licensing laws for Physical and Occupational Therapists in the state, and also recommended that the Committee on State Health Relations contact the Committee on Public Policy and Mr. Manley Brist, relative to the proper drafting of this matter for presentation to the legislature.

The Council referred to the Committee on Interprofessional Relations the recommendation of the American Pharmaceutical Association that a label "See your Physician" be placed on all preparations which carry the legend, "This preparation to be sold only on prescription."

The Council recommended that the House of Delegates pass a resolution supporting Senator Cain's resolution to investigate the administration of the office of social security, a resolution opposing Reorganization Plan No. 27 and H. R. 6000. Dr. Campbell then asked Dr. Reuben F. Erickson, Chairman of the Committee on Public Policy, to explain any proposed resolutions. Dr. Erickson explained that the association was not opposed to social security, per se, but only to weaknesses in administration of financial matters, etc. He then read Senator Cain's resolution, which suggests the creation of a Social Security Commission to advise the Congress and to provide the impartial technical knowledge required. Dr. Erickson urged members of the House of Delegates to return to their communities and write many individual letters to Senators, opposing the adoption of Reorganization Plan No. 27.

The report of the Council was accepted by the House.

At this time, Dr. Sheppard asked Dr. Elias to introduce two guests. Dr. Elias introduced Mrs. Henry E. Bakkila, Duluth, President, Woman's Auxiliary to the Minnesota State Medical Association, and Mrs. David B. Allman, Atlantic City, New Jersey, President, Woman's Auxiliary to the American Medical Association.

Next was the report of the Resolutions Committee, Dr. Wilson, Chairman.

Resolutions Committee Report

WHEREAS, the House of Delegates acknowledges and appreciates the valuable contributions of many groups and individuals to the success of the ninety-seventh annual meeting of the Minnesota State Medical Association,

NOW, THEREFORE BE IT RESOLVED, that specifically the House of Delegates extends thanks:

To the officers and members of the St. Louis County Medical Society, the St. Louis County Medical Auxiliary and the Committee on Local Arrangements for their constant efforts in arranging many parts of the program and in imparting the hospitality of the conference city;

To the management of the Hotel Duluth, Hotel Spalding, Hotel Holland, Hotel 5th Avenue, Hotel Lenox, Hotel McKay, Hotel Lincoln, Hotel Cascade, Hotel Arrowhead and Hotel Hamilton for prompt and courteous attention and service to convention guests and delegates;

To Radio Stations KDAL, WEBC and WREX for making available their facilities for the schedule of broadcasts in connection with the meeting; and

To the *Duluth Herald News-Tribune*, the *Minneapolis Star*, the *Minneapolis Tribune*, the *St. Paul Dispatch*, the *St. Paul Pioneer Press*, the *Associated Press* and the *United Press* for their fine advance notices and excellent coverage of the annual meeting.

* * *

WHEREAS, since the federal food and drug administration released the anti-histamine drugs, for the prevention and treatment of the common cold and hay fever, for sale over the drug store counter, without a physician's prescription, there has been an enormous and very promiscuous use of these drugs, and

WHEREAS, several of the manufacturing drug concerns have recently been cited by the federal government for misrepresenting their products, as the drug supreme in the prevention and treatment of the common cold and hay fever, and

WHEREAS, it is known to the medical profession that the promiscuous use of anti-histamine drugs, has resulted in many untoward reactions, many times serious, causing personal and industrial accidents; and in some instances, deaths have been reported throughout the United States, due to sensitization of over-dosage of these drugs, NOW THEREFORE,

BE IT RESOLVED that the House of Delegates of the Minnesota State Medical Association, in session at the annual meeting in Duluth, Minnesota, June 12, 1950, go on record as opposed to further over-the-counter distribution of these anti-histamine drugs, in order to protect the general public against the continued promiscuous use of these drugs, and

BE IT FURTHER RESOLVED, that we also inform the federal food and drug administration of this action and ask them to stop the uncontrolled use of such drugs and that their use be limited to the written prescription of the patient's physician.

* * *

WHEREAS, the Reference Committee on Medical Economic Reports has considered the report of the standing Committee on Interprofessional Relations and

WHEREAS, in spite of prolonged and diligent efforts on the part of the Interprofessional Relations Committee in the years past, no rapprochement with committees from other interested organizations has yet been reached, and

WHEREAS, no relief of the nursing shortage has so far been obtained, particularly in rural hospitals, and

WHEREAS, the public is becoming increasingly critical of the high cost of hospital care and the deteriorating service due to lack of trained nursing help, and

WHEREAS, present existing hospitals can and would train so-called practical nurses if a statewide uniform minimum curriculum were established, and

WHEREAS, the term "practical" nurse is generally unsatisfactory,

THEREFORE BE IT RESOLVED that the Minnesota State Medical Association go on record as recommending

First, the training of an adequate number of practical nurses, the training period of these nurses not to exceed two years,

Second, that this group of nurses shall have a special title to distinguish them from registered nurses,

Third, that the legislature of Minnesota be requested to create a board separate and distinct from the present Registered Nurses board, to supervise the training and licensing of this group of nurses.

BE IT FURTHER RESOLVED that our committee on Interprofessional Relations together with the committee on Public Policy be instructed to further this action by sponsoring and supporting appropriate legislation at the next session of the state legislature.

* * *

WHEREAS, the Honorable Oscar Swenson of Nicollet County, a member of the Minnesota Legislature for more than thirty years, has had the misfortune of being temporarily incapacitated because of illness; and

WHEREAS, the said Honorable Oscar Swenson has always been an ardent advocate of the highest standards in medicine, including sponsorship of the Minnesota Basic Science Law and reasonable appropriations for the teaching of medicine and the allied healing arts; NOW, THEREFORE,

BE IT HEREBY RESOLVED that the Minnesota State Medical Association, in annual session assembled, does hereby, through its House of Delegates, express our sincerest wishes for the early and complete recovery of the said Honorable Oscar Swenson and assure him of our appreciation for the many contributions that he has made, as a statesman, for the well-being of the people of our state; and

BE IT FURTHER RESOLVED that a copy of this resolution be forwarded to the Honorable Oscar Swenson, as a small token of the esteem in which we hold him.

The House of Delegates approved all of the resolutions.

Election of Officers

The next order of business was the election of officers. The House of Delegates elected the following:

President-Elect—J. F. Norman, M.D., Crookston.
First Vice President—Willard White, M.D., Minneapolis.
Second Vice President—A. E. Brown, M.D., Rochester.
Secretary—B. B. Souster, M.D., St. Paul.
Treasurer—W. H. Condit, M.D., Minneapolis.
Speaker, House of Delegates—C. G. Sheppard, M. D., Hutchinson.
Vice-Speaker—H. M. Carryer, M.D., Rochester.
Councilor, First District—John Waugh, M.D., Rochester.
Councilor, Second District—Roscoe C. Hunt, M.D., Fairmont.
Councilor, Ninth District—A. O. Swenson, M.D., Duluth.

Meeting Place 1951 Convention

The final order of business was the selection of the meeting place for the 1951 annual meeting. The House of Delegates voted to accept the invitation from the Olmsted - Houston - Fillmore - Dodge County Medical Society to hold the meeting in Rochester.

At 3 p.m. the Ninety-seventh Annual Meeting of the House of Delegates of the Minnesota State Medical Association was adjourned.

Constipation in the Aged...

The commonly encountered constipation of the older age group may result from reduced activity, lack of appetite for bulk-producing foods and inadequate ingestion of fluids.

By providing hydrophilic "smoothage" and gently distending bulk, Metamucil encourages normal physiologic evacuation without straining or irritation.

TWIN CITY BLOOD BANKS ARRANGE RECIPROCAL "POOL"

Patients in need of Red Cross blood in either Saint Paul or Minneapolis can now get it easier and faster than before because of a new reciprocal blood "pool" program set up between the Saint Paul Red Cross Regional Blood center and the Minneapolis War Memorial Blood Bank.

Under the new arrangement, patients in Minneapolis or Saint Paul hospitals from counties participating in the Red Cross program can now receive blood immediately when needed from the blood bank in the city in which they are hospitalized. Such patients are under no obligation to have friends or relatives replace this blood, because it will be furnished by the blood bank in which their donor club takes part.

For instance, a patient in a Minneapolis hospital from a county which participates in the Red Cross blood program and which has credit for blood in Saint Paul, can receive blood when needed from the Minneapolis War Memorial Blood Bank. It will be replaced by the Saint Paul Regional Blood Center. Likewise, members of donor clubs in the Minneapolis War Memorial Blood Bank who may become patients in Saint Paul hospitals

(Continued on Page 830)

Now Available . . . .

Complete, modern facilities of the Glenwood Hills Hospitals; co-ordinated to give an accurate diagnosis and proper treatment to the neuropsychiatric patient.

These unique facilities include:

- The outstanding staff of neurologists and psychiatrists in the United States
- The new Electroencephalograph
- The new Electrocardiograph
- An ultra-modern laboratory
- A completely equipped x-ray room
- Occupational therapy and Hydrotherapy
- A new physical education department
- Nurses specially trained in our own neuropsychiatric training school

NOW BEGINNING—

The September class for the School of Neuropsychiatric Nursing. Prospective candidates should apply and register immediately.

One year course—tuition free

GLENWOOD HILLS HOSPITALS

3901 GOLDEN VALLEY ROAD MINNEAPOLIS 22, MINN.

Offering a High Standard of Facilities for 25 Years

TWIN CITY BLOOD BANKS ARRANGE RECIPROCAL "POOL"

(Continued from Page 828)

can receive blood there from the Saint Paul Red Cross Regional Blood Center. The blood will be replaced from the particular donor club's credit at the Minneapolis War Memorial Blood Bank.

The new program, set up through the efforts of Dr. E. V. Goltz, Medical Director of the Saint Paul Red Cross Regional Blood Center and G. Albin Matson, Director of the Minneapolis War Memorial Blood Bank, was developed because of various complications in the previous system.

With the new system, the patient from a Red Cross participating county, hospitalized in either city, receives the same benefits as are received by patients who are members of donor clubs in the Twin Cities.

INTERNATIONAL COLLEGE OF SURGEONS

The fifteenth annual assembly of the United States Chapter of the International College of Surgeons will be held in Cleveland, Ohio, October 31 to November 3, with headquarters at the Cleveland Hotel.

Surgical clinics will be held in several Cleveland hospitals on Monday, October 30. All scientific sessions will be held at the Cleveland Public Auditorium 9:00 a.m. to 5:00 p.m., Tuesday through Friday. A most excellent program has been arranged at which time some of the most prominent surgeons of America, and some foreign speakers, will discuss the current contemporary surgical scene.

Through the courtesy of Smith, Kline and French Laboratories, a fine colored television program of surgical procedures, originating from the St. Vincent's Charity Hospital, Cleveland, will be shown daily in the auditorium from 9:00 a.m., to 1:00 p.m. Motion pictures will also be presented each day depicting many of the recent advances in surgery and surgical technique.

One of the highlights of the meeting will be the annual banquet at the Statler Hotel on Thursday evening when America's great surgeon, Dr. Frank Lahey of Boston, will talk on "Some of the Recent Advances in Surgery." Dr. Elmer Henderson, President of the American Medical Association, will deliver an address on "The Importance of International Co-operation in Surgery."

Reservations may be secured by writing to the Committee on Hotels, International College of Surgeons, 511 Terminal Tower, Cleveland 13, Ohio. Preliminary programs may be obtained from the central office, 1516 Lake Shore Drive, Chicago 10.

AMERICAN ROENTGEN RAY SOCIETY

The American Roentgen Ray Society will hold its fiftieth anniversary meeting in St. Louis, September 26-29.

The scientific sessions and the scientific and commercial exhibits will be held in the Hotel Jefferson in St. Louis.

This year's Caldwell Lecture will be delivered on September 27 by Dr. Henry L. Bockus, professor and chairman of the Department of Internal Medicine in the Graduate School of Medicine, University of Pennsylvania, Philadelphia. His subject will be "The Role of Roentgenology in Gastroenterology."

The convention program is being arranged by a committee headed by President-elect B. P. Widmann, M.D., of Philadelphia.

The society president is Dr. U. V. Portmann, of Cleveland.

NEW FILM ON CANCER

"Self-Examination of the Breast" is the name of a new sound, color, 16 mm. film that has been produced by the Cancer Institute and the American Cancer Society.

This film demonstrates how women can and should systematically examine their breasts to detect changes that may be due to early cancer. Change of contour, size dimpling, and lumps are stressed, with advice to make examinations of the breasts periodically and go to the doctor at once if anything unusual is detected. This film will be shown widely to groups of women throughout Minnesota.

"All practicing physicians should see this film so that they will be familiar with the instructions in self-examination their patients are attempting to carry out and have an understanding attitude towards the many women who will come to their office because they think they have discovered something wrong," says Dr. A. H. Wells, president of the Minnesota Division, American Cancer Society.

The Minnesota Division of the American Cancer Society and the Minnesota Department of Health have prints of the film, and arrangements can be made to show it at county medical society meetings or hospital staff meetings.

RESEARCH IN ARTHRITIS

The Arthritis and Rheumatism Foundation is offering fellowships for research in the basic sciences related to the study of arthritis. These fellowships carry a stipend of from $4,000 to $6,000, depending upon the needs and ability of the worker, and run for a period of one year. The fellowships would begin in July, 1951, although earlier appointments would be considered by the committee.

The Foundation is eager to back a candidate, rather than a project, an institution, or a hospital. It hopes to arouse interest in arthritis in a wider circle of medical investigators and to encourage able, inquiring minds.

Applications should be sent to the Arthritis and Rheumatism Foundation, 535 Fifth Avenue, New York 17, New York, by January 1, 1951. Notification of the fellowships granted will be made March 1, 1951.

If any applications are received by September 15, 1950, they will be acted on at that time and notification made immediately.

MINNESOTA SOCIETY OF CLINICAL PATHOLOGISTS

The annual session of the Minnesota Society of Clinical Pathologists was held in Duluth, June 12, 1950, during the annual meeting of the Minnesota State Medical Association. It was featured by the Society's annual A. H. Sanford Lecture before a general session of the association by Ancel Keys, Ph.D., on the subject of "Diet and Cardiovascular Disease," and by an all-day tumor seminar under the direction of Dr. Robert Hebbel of the University of Minnesota, and his associates, Drs. John McDonald and Malcolm Dockerty of the Mayo Clinic. The seminar was made possible by a grant of $300.00 contributed by the Minnesota Division of the American Cancer Society, and attended by thirty members who expressed enthusiastic approval of the manner in which it was conducted, and of the material presented. The Society voted to make the seminar an annual feature event. The fall meeting is scheduled in Minneapolis. The officers elected for the ensuing year are: President, John F. Noble; Vice president, James McCartney; Secretary-Treasurer, Kano Ikeda; Councillors, John McDonald, William Knoll, and Nathaniel Lufkin.

COURSE IN POSTGRADUATE GASTROENTEROLOGY

The National Gastroenterological Association is again offering a course in postgraduate gastroenterology on October 12, 13, and 14, at the Hotel Statler in New York City, immediately following the fifteenth annual convention, to be held at the same place on October 9, 10 and 11.

The course will be under the personal direction of Dr. Owen H. Wangensteen, of the University of Minnesota Medical School, who will be the surgical co-ordinator, and Dr. I. Snapper, of Mt. Sinai Hospital and the College of Physicians and Surgeons, Columbia University, who will be the medical co-ordinator. They will be assisted by a distinguished faculty.

The course is open to members and non-members of the Association who have had adequate preliminary training. However, preference in registration will be given to members of the Association. The course will not be available under the provisions of the GI Bill of Rights because of the many difficulties in obtaining certificates of eligibility and other necessary Veterans Administration forms.

The fee is $25 for the three days for those affiliated with the National Gastroenterological Association, and $35 for non-members. Registration blanks may be obtained from Mr. Daniel Weiss, 1819 Broadway, New York 23, N. Y.

POSTGRADUATE SEMINARS

The University of Minnesota School of Medicine in conjunction with the Minnesota State Medical Association and the Minnesota Department of Health will hold six professional medical postgraduate seminars throughout Minnesota during 1950-1951.

The areas, together with approximate attendance dates, are these:

1950

Crookston—September 13 to November 1
Virginia—September 21 to November 9

1951

Moorhead—January 3 to February 21
Willmar—January 11 to March 1
Worthington—March 6 to April 24
Albert Lea—March 14 to May 2

The seven courses held throughout the state in 1949-50 were extremely well received and professional attendance and interest was excellent.

Heart disease, cancer control, and mental health will be the subjects of this year's programs. Latest information on the diagnosis, treatment, and management of diseases in these three fields will be presented by leading medical lecturers from the University of Minnesota School of Medicine. Professional films and literature will in some instances be used to augment the speakers.

POSTGRADUATE SEMINARS

(Continued from Page 832)

Each seminar, as last year, will consist of eight consecutive weekly meetings, with each session about two hours long. Ordinarily two speakers, each on a different subject matter, will appear.

There is no charge for this series of lectures unless local physicians voluntarily assess themselves $2.00 each to obtain a certificate of attendance.

County medical societies are actively cooperating in the organization and conduct of these significant medical education events.

Coincident with these medical seminars, dentists and nurses of the area will hold eight sessions of their own, patterned generally after the physicians' courses, with subject matter tailored to their specific interests. The University of Minnesota Schools of Dentistry and Nursing, the Minnesota State Dental Association, the Minnesota State Nurses' Association, and local dental and nursing groups sponsor the seminars.

Other co-sponsors of the seminars are: The Minnesota Division of the American Cancer Society, the Minnesota Heart Association, and the Minnesota Mental Hygiene Society.

CONTINUATION COURSE

Female and male infertility will be the subject of the continuation course to be presented by the University of Minnesota on September 28-30. The course, intended for physicians specializing in obstetrics and gynecology, will be presented at the Center for Continuation Study. Distinguished visiting physicians who will participate as faculty members will include Dr. Warren O. Nelson, University of Iowa College of Medicine; Dr. Isador C. Rubin, Mount Sinai Hospital and New York University College of Medicine; and Dr. Fred A. Simmons, Harvard University Medical School. Staff members of the University of Minnesota and the Mayo Foundation will complete the faculty for the course.

Key topics which will be discussed during the three-day course include psychosomatic aspects of sterility, the investigation and management of the infertile couple, the management of amenorrhea, and artificial insemination.

SOUTHERN MINNESOTA MEDICAL ASSOCIATION

The Southern Minnesota Medical Association will hold its annual meeting on Monday, September 11, at Mankato, Minnesota. All physicians are welcome at the meeting, and applications for membership will be considered during the business meeting.

The program for the meeting is as follows:

"Hospital Management of Asthma" by Dr. Giles Koelsche of Rochester.

"Basic Facts About Gallbladder Surgery for General Physicians" by Dr. David P. Anderson of Austin.

"Common Injuries of the Knee Joint" by Dr. E. D. Henderson of Rochester.

"Thrombocytogenic Purpura" by Dr. Charles Stroebel of Rochester.

"Antabuse in the Treatment of Alcoholism" by Dr. J. C. Michael of Minneapolis.

"Trauma to Urethra and Bladder in Association with Pelvic Fractures" by Dr. E. J. Richardson of St. Paul.

"Urinary Acetone: Its Detection and Value in Treating Ambulatory Diabetics" by Dr. B. J. Mears of St. Paul.

"Management of Spontaneous Pneumothorax" by Dr. W. R. Schmidt of Minneapolis.

"Differential Diagnosis of Low Back and Sciatic Pain" by Dr. H. J. Svien of Rochester.

"Operative Measures to Improve Circulation in Arteriosclerosis Obliterans" by Dr. F. W. Quattlebaum of St. Paul.

"Emergencies in the Newborn Period" by Dr. L. E. Harris of Rochester.

"Acute Yellow Atrophy of Liver from S. H. Virus, Transmitted by a Blood Bank" by Dr. Winston R. Miller of Red Wing (Case Report).

"Shattered Kidney in Four-year-old Child" by Dr. R. I. Gruys of Windom (Case Report).

"Low Backache with Sciatic Pain" by Dr. L. I. Younger of Winona (Case Report).

PENNINGTON COUNTY SOCIETY

The Pennington County Medical Society was organized at a dinner meeting in Thief River Falls on June 29. It was announced that officers would be elected at a later meeting.

The initial meeting was highlighted by six guest speakers from the University of Minnesota Medical School who were on their way to Lake of the Woods for a brief fishing expedition. The six speakers were Dr. Clarence Dennis, Dr. Howard Horns, Dr. Arnold J. Kremen, Dr. Lyle Hay, Dr. Robert Hebbel and Dr. Robert Huseby.

SOUTHWESTERN MINNESOTA MEDICAL SOCIETY

The Southwestern Minnesota Medical Society held its regular monthly meeting at Worthington on June 26. Principal speaker of the evening was Dr. Rudolph W. Koucky, Minneapolis, who discussed advances in the diagnosis and treatment of diseases of the blood.

Dr. and Mrs. F. M. Manson, Worthington, were honored guests at the dinner meeting in recognition of the physician's having just become a member of the Fifty Club of the Minnesota State Medical Association.

The BCG vaccination campaign against tuberculosis is progressing throughout the world. As of March 1, twenty million children and young adults have been tested, and about ten million vaccinated against tuberculosis. Mass vaccination campaigns were completed in Czechoslovakia and Finland last summer, and will finish in Poland this spring. Work is under way in Austria, Greece, Yugoslavia, Morocco, Ceylon, India, Pakistan, Algeria, Tunisia, Italy, Egypt, Israel and Lebanon. Campaigns will soon begin in Syria, Malta, Mexico and Ecuador. BCG vaccination campaigns are a joint enterprise of UNICEF, Scandinavian relief societies and WHO.—*WHO Newsletter,* February-March, 1950.

In Memoriam

ERNEST L. BAKER

Dr. Ernest L. Baker of Minneapolis passed away July 20, 1950, just five days after celebrating the fortieth anniversary of his practice in Minneapolis.

Dr. Baker was born in Ithaca, Michigan, January 9, 1880. He attended the University of Michigan at Ann Arbor and the North Dakota Agricultural College and taught for five years as principal of grade and high schools in North Dakota, Iowa City and Fairmont. He then attended medical school at the University of Minnesota, where he received his medical degree in 1909. He was the first intern at the University Hospital, where he served from March 10, 1909 until July, 1910, in the building on Washington Avenue which had been converted from a former residence into a hospital and was used as such until the construction of the first unit of the present University Hospitals.

While in general practice, Dr. Baker maintained an office in Southeast Minneapolis. He was associated with Dr. George Douglas Head for a number of years.

Dr. Baker was a member of the Hennepin County Medical Society, the Minnesota State Medical Association and the American Medical Association. He was also a member of Alpha Omega Alpha, honorary medical society, and Nu Sigma Nu, undergraduate medical fraternity.

Dr. Baker is survived by his wife, Ethel Bliss Baker; a son, Dr. Milton E. Baker; a daughter, Priscilla Baker Cross; a brother, Henry C. Baker, Portland, Oregon; a sister, Mrs. William Newell, Onstet, Michigan, and four grandchildren. A son, Douglas Baker, preceded his father in death. Mrs. Baker had the distinction of being desigated "Minnesota Mother" in 1944.

BERTON J. BRANTON

Dr. B. J. Branton, mayor of Willmar commonly known as B. J., died on May 9, 1950. He was president of the Minnesota Public Health Association and was in the midst of the x-ray campaign being conducted in Kandiyohi County when stricken.

Dr. Branton was born in Willmar, September 20, 1883. He graduated from the University of Minnesota medical school in 1905 and interned at the Budd Hospital at Two Harbors and at St. Barnabas Hospital in Minneapolis.

Dr. Branton founded the Willmar Hospital in 1937. He was most active in local affairs. At the time of his death he was vice president of the Bank of Willmar, a member of the Board of the Kandiyohi County Fair, president of the Willmar Shrine Club, as well as mayor of Willmar. He had been Coroner of Willmar for a period of twelve years and was a past president of the Elks and the Kiwanis clubs. He had been president of the Willmar Chamber of Commerce and chairman of the Kandiyohi County Historical pageant held in 1949. He had been president of the Kandiyohi-Swift County Medical Society, president of the Northern Minnesota Medical Association, and in 1941 was president of the Minnesota State Medical Association. He was also a member of the American College of Surgeons, the Kandiyohi-Swift County Medical Society, the Minnesota State Medical Association and the American Medical Association. He was head of the Willmar Clinic, which he established at the time the Rice Hospital opened. He also headed the Branton Properties and the Branton Foundation. According to newspaper accounts, he was Willmar's leading citizen.

On July 11, 1906, he was married to Alice A. Brown. Surviving are one son Calvin F. Branton of Saint Paul and two daughters, Alice (Mrs. Clifford Marlow) of Willmar and Elizabeth (Mrs. Chester I. Miller) of Minneapolis.

* * *

It is a great privilege to pen a tribute to our recently departed comrade, Bertram J. Branton. Nothing would be added by enumerating again the many honors bestowed upon him and the distinguished services he rendered in various capacities; so briefly I shall mention some of the characteristics which distinguished him.

He lived an efficient well-balanced life from youth to maturity.

He was a man of high intelligence, and one who had his mind under control, constantly holding it to some worthwhile endeavor.

He was a shrewd businessman, but never allowed his personal desires to overbalance the public good.

He was an ambitious man, but his ambitions were chiefly directed towards the public interests.

He was an able physician and surgeon, using his skill not so much for personal aggrandizement as for the public welfare.

He was public spirited, giving of his time and talents to advance the interest of his community and to promote the welfare of the state and country.

He was a moral man and lived by his ideals day in and day out.

Bertram J. Branton is one of the rare examples of a man who throughout life had courage and force of character sufficient to live each day in the best way possible. He died with no worry about what he should or should not have done.

We physicians are justified in a feeling of pride that, as a group, we have produced more men of this type than any other group; and in particular, the Minnesota State Medical Association can be proud that it has contributed more than its share of such men. May we ever hold high the standard of service exemplified by Bertram J. Branton.

W. L. Burnap, M.D.

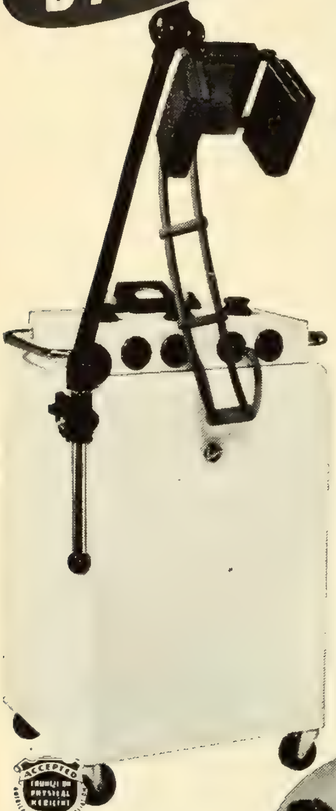
BIRTCHER

Crystal BANDMASTER

SHORT WAVE DIATHERM with the TRIPLE INDUCTION DRUM



The Bandmaster has been approved or accepted by the following:

✓ A.M.A. Council on Physical Medicine

✓ Federal Communications Commission

✓ Underwriters' Laboratory

✓ Also the Canadian Department of Transport and Canadian Standards Association

The Bandmaster Diatherm with the Triple Drum provides better diathermy and affords application of the large area technic which is being widely recognized over other methods of producing heat in the tissues.

Considerable total energy may be introduced into the deeper tissues without excessive heating of outer surfaces. Crystal control assures frequency stability for life of the unit.

Reprint of diathermy technics mailed free on request. Write "Bandmaster Booklet" on your prescription blank or clip this advertisement to your letterhead and mail to:

ARCHIBALD E. CARDLE

On June 23, 1950, in the worst air disaster in American history, Medicine lost one of its most able and distinguished members, and one of its most sincere and untiring servants. The entire medical profession, his friends and patients mourn the death of Dr. A. E. Cardle.

Dr. Cardle was born in El Reno, Oklahoma, April 27, 1899. He was graduated from the University of Iowa medical school in 1923, served an internship at Maryland General Hospital and a residency at the Minneapolis General Hospital. He entered practice in Minneapolis, associating himself with Dr. J. G. Cross in the practice of internal medicine. After Dr. Cross' death, he continued alone.

Dr. Cardle had been a delegate to the House of Delegates of the Minnesota State Medical Association, Councilor for the Sixth District for six years before becoming President of the Minnesota State Medical Association in 1948, the Association's youngest President. Since 1946 he had been Secretary of the Minnesota Academy of Medicine.

He had been named a delegate from Minnesota to the 1950 meeting of the American Medical Association and was returning from the East preparatory to leaving for San Francisco when he died, one of fifty-eight lost that stormy night over Lake Michigan.

In final tribute to a fine man and a good doctor, may I say in behalf of those who knew him well that to work with "Arch" was a joy and a privilege.

His excellent judgment helped steer Medicine through some turbulent times. He had a rare faculty for understanding the public's reaction toward the medical profession and was unexcelled in interpreting Medicine's accomplishments and objectives to the public.

In his capacity as chairman of the Public Health Education Committee, Arch played the leading role in our successful efforts to swing an enlightened public against compulsory health insurance.

The advertising campaign now being so extensively conducted in the newspapers throughout the state is largely Arch's "brain child," and was prepared under his direction by an experienced and talented public relations expert. In national medical circles, he was receiving increasing recognition for his sincere and effective efforts in public education and, had he been spared, unquestionably he would have been called upon to expand his activities beyond our own state.

Arch's modest demeanor, his exceptional kindliness, unfailing optimism and good humor will be sorely missed by all who have been privileged to enjoy his friendship.

He is survived by his wife, Edith, and two children, Mary and John.

OSCAR J. ESSER

Dr. Oscar J. Esser, of New Ulm, a specialist in eye, ear, nose and throat diseases, died July 7, 1950, at the age of forty-eight.

Oscar Esser was born September 27, 1901, in Dane County, Wisconsin. He moved with his parents to New Ulm as a child. His medical education was obtained from Marquette University medical school where he graduated in 1927.

He practiced for short periods at Ossian, Iowa, and later at Gibbon and New Ulm, maintaining offices in both towns. He then practiced at Tracy for a time. Two years ago he entered the New York City Polyclinic and took a special course in eye, ear, nose and throat diseases. He returned to New Ulm to practice but maintained his home at Gibbon.

Dr. Esser was a member of the Brown County Medical Society, the Minnesota State Medical Association and the American Medical Association.

Dr. Esser married Florence Stadtherr of Gibbon November 27, 1924. He is survived by his widow, two sons and a daughter. His mother, three brothers and three sisters also are living.

JOHN S. KILBRIDE

Dr. John S. Kilbride of Canby, Minnesota, passed away June 5, 1950, following an injury received in an automobile accident shortly before Christmas in 1949. He was eighty-four years of age.

Dr. Kilbride was born at Zwingle, Iowa, December 23, 1865. He attended high school at Dubuque, Iowa, and the Iowa State Academy at Iowa City. He received his M.D. degree from the College of Physicians and Surgeons at the University of Illinois in 1893. He took postgraduate work at the New York and Chicago Postgraduate schools and in 1910 continued his studies in Vienna.

He began practice in Dawson, Minnesota, in 1898 and after a year went to Sleepy Eye, where he practiced for a year before going to Canby. After returning from Vienna in 1910 he practiced at Watertown, South Dakota, for four years. In 1915 he and Dr. L. J. Holmberg formed a partnership in Canby which continued until 1936 when he joined his son, Dr. Edwin Kilbride, in Worthington. In 1943 he returned to Canby to practice until the war ended in 1945, when he returned to Worthington.

He was a former member of Nobles County Medical Society, the Minnesota State Medical Association and the American Medical Association.

Dr. Kilbride is survived by his son, Dr. Edwin Kilbride of Worthington, Linnae Kilbride, an attorney in Hastings, Zylpha Kilbride of Evanston, Illinois, and Kathleen (Mrs. Nelson Knoop) of DesPlaines, Illinois.

VERNON L. HART

Dr. Vernon L. Hart, well-known orthopedic surgeon of Minneapolis, drowned in Cedar Lake, Minneapolis, on July 12, 1950. He was fifty-one years of age.

Dr. Hart was born in Huron, Ohio, October 24, 1898. He obtained his M.D. degree from the University of Michigan in 1924 and took further training in surgery at the University Hospital, Ann Arbor, from 1924 to 1932.

Dr. Hart practiced at Dayton, Ohio, from 1932 to 1933, when he moved to Minneapolis to take over the orthopedic practice of the late Dr. Emil Geist. He was known for his work on congenital dislocation of the hip before he moved to Minneapolis.

Dr. Hart was a Fellow of the American College of Surgeons, a diplomate of the American Board of Orthopedic Surgeons, a member of the American Academy of Orthopedic Surgeons, the Clinical Orthopedic Society, the Minnesota Academy of Medicine, the Hennepin County Medical Society, the Minnesota State Medical Association and the American Medical Association.

Dr. Hart held the rank of Lieutenant Colonel in World War II and headed the orthopedic service at several army hospitals. He was also a member of the National Research Council and was a civilian consultant to the Surgeon General of the United States Army on a six-weeks inspection of the American Zone of Germany in in 1948.

Survivors are his wife and daughter, Louisa K.; a sister, Mrs. Vanessa Campbell of Huron, Ohio, and a brother, Vincent, of Cleveland, Ohio.

HORATIO B. SWEETSER

Dr. Horatio B. Sweetser, a prominent surgeon of Minneapolis until his retirement in 1933, died May 23, 1950, at the age of eighty-eight.

Dr. Sweetser was born in Brooklyn, New York, July 13, 1861. He graduated from St. John's College in Brooklyn in 1877 and received his medical degree from the College of Physicians and Surgeons in New York in 1885. After interning at St. Francis Hospital, New York City in 1885-1886 he practiced in New York City for a brief period before coming to Minneapolis in 1887.

He was professor of anatomy and surgery at Hamline University Medical School and later at the University of Minnesota Medical School after the two schools were merged. He was a charter member of St. Mary's Hospital in Minneapolis, having been a member since 1887 and was chief of staff for many years.

Among the many organizations of which Dr. Sweetser was a member may be mentioned: the American College of Surgeons, the Western Surgical Association, the Minnesota Academy of Medicine of which he was president in 1919, the Minneapolis Surgical Society of which he was president in 1927, the Hennepin County Medical Society of which he was president in 1899-1900, the Minnesota State Medical Association and the American Medical Association.

He belonged to Phi Rho Sigma, the undergraduate medical fraternity and was a member of the Minneapolis Club, the Minneapolis Auto Club and the Bloomington Golf Club.

Dr. Sweetser is survived by two sons, Dr. Theodore H. Sweetser and Dr. Horatio B. Sweetser, Jr., of Minneapolis; and two daughters, Mrs. Frank Preston of Minneapolis and Mrs. Elizabeth Albrecht of Belle Plaine.

Dr. Sweetser was a fine gentleman and an expert surgeon. His pleasing personality and character won him a multitude of friends.

KENNETH G. WILSON

Word has been received of the death of Dr. Kenneth G. Wilson on June 19, 1950.

Dr. Wilson, who was a former fellow in ophthalmology and aviation medicine at the Mayo Foundation, was born in Minneapolis on August 27, 1915. He received his M.D. from the University of Minnesota and interned at St. Luke's Hospital in San Francisco. He entered the Mayo Foundation as a fellow in ophthalmology in July, 1941; later, he became interested in, and transferred his major subject to, aviation medicine. He left the Mayo Foundation in February, 1943, to go to Cleveland to practice aviation medicine and later moved to San Diego. At the time of his death he was residing in Laguna Beach, California.

Dr. Wilson was a member of the Psi Upsilon and Nu Sigma Nu fraternities.

Tuberculosis rates . . . rose in every European country seriously affected by the war, and there is now a growing realization in Europe that tuberculosis is our main public health problem.—Marc Daniels, M.R.C.P., D.P.H., *British Medical Journal,* Nov. 12, 1949.

Woman's Auxiliary

AUXILIARY REPORTS AT AMA CONVENTION

The Woman's Auxiliary to the Minnesota State Medical Association reported to the national convention in San Francisco in June. Mrs. Charles W. Waas, the new president, read the report of the immediate past president, Mrs. H. E. Bakkila.

Highlights from the report state that Minnesota has twenty-nine auxiliaries and one branch, all working closely with their medical societies. Area health and guest days are gaining in popularity. Lay groups assist in planning and all voluntary health organizations are exhibitors. A book on health day procedure has been written with the aid of the State Department of Health. The Auxiliary sponsored the nineteenth annual State High School radio contest on tuberculosis.

A Public Relations Workshop, co-sponsored by the Minnesota State Medical Association, was held, consisting of a panel discussion of "Fundamentals of Community Health Education Program." Such media as press relations, distribution of literature, speakers bureau, radio, exhibits, personal contacts and health days were discussed. A new project is a "Five-Point Basic Program for Improvement of School Health Services."

During the year, the Auxiliary was visited by Mrs. David Allman, national president, and Mrs. Paul Craig, national public relations officer.

All county auxiliaries have had health education as their main project. One auxiliary had a study group, presenting such topics as "Your Hospital Dollar and Where It Goes," and "Co-operative Medicine." The president of the Minnesota State Medical Association addressed them. Another auxiliary sponsored a weekly radio program, "Your Health Hour." Most auxiliaries have volunteered their services, as well as financial aid, to the Cancer Society, Christmas seal sales, Red Cross drives, the Society for the Prevention of Blindness, the Mental Hygiene Society, the Nurses Scholarship and the Heart Association. The Auxiliary has a representative on the State Nutrition Committee, also many members are serving on boards and as officers of clubs throughout the state. One member is president of the state branch of the American Association of University Women.

Cooperation of officers and the aid of every individual member have combined to produce a successful year for the Woman's Auxiliary to the Minnesota State Medical Association.

Mrs. Benjamin B. Souster
Saint Paul

◆ Of General Interest ◆

Ground-breaking ceremonies for the twenty-two-story **Mayo Memorial Medical Center** at the University of Minnesota were held on July 5. Dr. J. L. Morrill, president of the University, turned the first shovelful of earth at the site of the structure in the quadrangle in front of the University Hospitals. Principal speaker for the occasion was Dr. Donald J. Cowling, chairman of the committee of founders of the Mayo Memorial.

It is expected that the $12,000,000 structure will be ready for occupancy in 1953. When completed, it will contain laboratories, classrooms, staff offices, three auditoriums, an underground garage, operating and hospital rooms, medical library, and quarters for research animals. The tower section will rise 250 feet above the ground.

* * *

Dr. Murray H. Hunter, formerly of Ancker Hospital, Saint Paul, has become associated in practice with Dr. A. H. Field of Farmington. A graduate of the University of Marquette Medical School, Dr. Hunter recently completed his internship at Ancker Hospital.

* * *

A testimonial dinner was given for **Dr. W. H. Valentine,** of Tracy, on May 27 by patients and fellow physicians in recognition of Dr. Valentine's fifty years of medical service to Tracy. The dinner was attended by 350 friends from Wisconsin and South Dakota as well as Minnesota.

Mr. William R. Mitchell presided as master of ceremonies, and the principal address was given by Dr. Roscoe C. Webb, of Minneapolis, a native of Amiret, who paid tribute to Dr. Valentine's service to the community. Other members of the profession called upon for remarks were Dr. H. J. Nielson, Dr. J. K. Helferty, Dr. W. G. Workman, Dr. G. W. Ferguson and Dr. R. R. Remsberg. Dr. S. A. Slater, Worthington, presented the honored guest with a certificate of recognition for his part in tuberculosis control and his work as president of the Lyon County Public Health Association for twenty-nine years. Congratulations were received from Governor Youngdahl and prominent medical and educational leaders in the state. Especially cherished was a telegram from the Sisters of St. Joseph, St. Mary's Hospital, Minneapolis. Dr. Valentine is the oldest living ex-intern of that hospital.

* * *

Dr. Wesley W. Spink, of the University of Minnesota Medical School, has been elected to the board of governors of the American College of Physicians. He will be governor for the organization in Minnesota until 1953. Dr. Spink was also given an honorary degree of Doctor of Science from Carleton College in June.

Dr. Richard A. Knudson, Forest Lake, announced late in June that he planned to leave his practice in Forest Lake about July 30 and move to Black River Falls Wisconsin. Dr. Knudson began his practice in Forest Lake in August, 1948. He was associated with Dr. J. A. Poirier for almost two years.

* * *

At a meeting of the North Dakota State Pediatric Society in Grand Forks on May 29, **Dr. Albert V. Stoesser,** Minneapolis, gave a talk at a luncheon and conducted a round-table discussion on "Modern Drug Therapy in Allergy." On the same day he spoke at the sixty-third annual meeting of the North Dakota State Medical Association in Grand Forks, discussing "Respiratory Allergy in Children."

In June, Dr. Stoesser attended the annual session of the AMA in San Francisco and spoke before the Section on Pediatrics on June 28. His subject was "Antihistamines in the Treatment of Allergic Diseases in Children."

* * *

After ten years of association with the Gamble Clinic in Albert Lea, **Dr. E. S. Palmerton** left on July 1 to specialize in ophthalmology at the University of Minnesota. Also on July 1, the Gamble Clinic changed its name to Nelson and Erdal, Physicians and Surgeons. It was announced that on August 1, Dr. Leonard M. Ellertson of Muncie, Indiana, would join the group in Albert Lea.

* * *

Dr. John L. Juergens has become associated with his father, Dr. H. M. Juergens, in the practice of medicine in Belle Plaine. A graduate of the Harvard Medical School, the younger Dr. Juergens interned at Minneapolis General Hospital.

* * *

On the evening of June 3, the medical department of the **University of Minnesota Medical School,** some 100 strong, attended a banquet at the Minneapolis Club in honor of three professors of medicine who have contributed outstanding service to the school—Dr. Henry Ulrich, Dr. S. Marx White and Dr. George Fahr.

It was Dr. Henry Ulrich who, as clinical professor of medicine, built up the University medical service at the Minneapolis General Hospital before it was taken over by Dr. George Fahr as full-time professor of medicine and chief of the medical service in 1927. More recently Dr. Ulrich taught at the University Hospitals until his retirement as emeritus professor in July, 1944. Dr. Fahr became emeritus professor on June 15 of this year. Dr. S. Marx White has given many years to teaching medicine at the University and was head of the department from

January, 1921, to November, 1925. He became emeritus professor in July, 1942.

Dr. Reuben Johnson, as toastmaster, entertained the banqueters with an apparently inexhaustible supply of stories, and tribute was paid to the honor guests by Drs. Lowry, Watson and Schaaf.

* * *

Dr. Gordon R. Kamman, Saint Paul, presented a paper on June 21 before the AMA Section of Nervous and Mental Diseases. His subject was "Traumatic Neurosis, Compensation Neurosis, or Attitudinal Pathosis?"

* * *

Dr. J. R. Harrie, formerly of Eveleth, began a three-year residency in radiology at the University of Michigan on July 1. Dr. Harrie became associated with the More Hospital in February, 1949, maintained offices in the More-Ewens Clinic in Virginia, and was city health officer at Mountain Iron.

* * *

Two Rochester couples sailed from New York on July 8 for a two-month trip through Europe. They were Dr. and Mrs. B. E. Hall and Dr. and Mrs. J. M. Stickney. For the two physicians, however, the trip was not planned to be just a vacation. Both Dr. Hall and Dr. Stickney were scheduled to speak at a meeting of the International Society of Hematology in England during August. In addition, Dr. Stickney spoke at the Fifth International Cancer Congress in Paris late in July, and Dr. Hall was scheduled to be on the program at the First International Congress of Internal Medicine in Paris during September.

* * *

An editorial in the *Crookston Daily Times* on July 11 paid tribute to **Dr. M. O. Oppegaard** as he began his fortieth year in the practice of medicine. After ten years of practice in various hospitals in the East, in New London and in Minneapolis, Dr. Oppegaard moved to Crookston in 1920. During his years there he has served in numerous civic and professional capacities, usually managing to handle several tasks simultaneously. He has been mayor of the city for three terms and holds that office at present.

* * *

Grants for cancer research announced by the Public Health Service on July 7 total $1,160,818. These awards will support cancer research in hospitals, universities and other non-federal institutions in thirty states and the District of Columbia. The grants were made by the National Cancer Institute following recommendations by the National Advisory Cancer Council and approval by Dr. Leonard A. Scheele, Surgeon General of the Public Health Service. Included are the following grants to the University of Minnesota: $8,023 to Dr. Edward Eaton Mason for investigation of gastric secretion and stomach cancer; $3,978 to Dr. Sheldon C. Reed for the study of biology of human breast cancer with particular emphasis upon heredity; $7,685 to Dr. Claude R. Hitchcock for chemical induction of stomach cancer in inbred strains of mice; $14,040 to Dr. Julian Wild for studying normal and malignant tissues by the use of ultrasound.

* * *

Dr. Robert L. Merrick has become associated with Dr. Wallace P. Ritchie at 917 Lowry Medical Arts Building, Saint Paul, for the practice of neurosurgery. Dr. Merrick is a native of Corydon, Iowa, and received his medical degree at the University of Minnesota in 1945. After serving in the Army for two years, he completed a residency in neurosurgery first at the Neurological Institute of New York and recently at the University Hospitals in Minneapolis.

* * *

Dr. Ralph Buesgens has opened offices in Waterville for the practice of medicine. A graduate of Creighton University, Dr. Buesgens recently completed his internship at St. Mary's Hospital, Minneapolis.

* * *

Two Mayo Clinic staff members, Dr. Lyle A. Weed and Dr. L. B. Woolner, were awarded silver medals by the AMA for their exhibit on cancers of the mouth at the annual meeting of the AMA in San Francisco during June.

* * *

Frederick J. Tenuto (alias Leonard Durham, Leonard Durken, John Thomas Lastella, Frank Pinto, Durso Thornberry, etc.) has escaped from the state of Pennsylvania to avoid confinement after conviction for the crime of murder. He is believed to be armed and is considered dangerous. Tenuto is thirty-five years of age, 5 feet 5 inches tall, weighs 143 pounds. He is stocky in appearance, has black hair, dark brown eyes and a dark complexion. He has an imperfect tattoo, S.J., on his left forearm and an imperfect tattoo, ANA, ANNA or AMA on his right forearm, a small brown mole on his right cheek and a one-and-one-half-inch scar over the right eye. A recurring skin eruption may lead him to seek medical care. **The office of the F.B.I.** in Minneapolis, Lincoln 6963, should be notified.

* * *

Dr. Gerald E. Larson and **Dr. Raymond C. Magnuson** opened offices in Cambridge on July 12 for the practice of medicine. Both physicians are 1949 graduates of the University of Minnesota Medical School and both served their internships in Duluth.

* * *

Miss Elsie T. Berdan has been appointed chief of the Nursing Branch, Division of Hospitals, Public Health Service. Miss Berdan is a native of Sleepy Eye. She graduated from St. Mary's Hospital School of Nursing in Minneapolis and later obtained both the Bachelor of Science and Master of Science degrees in nursing education at the Catholic University of America in Washington, D. C. Prior to her present appointment she served as associate chief of the Nursing Branch in the Division of Hospitals under Miss M. Constance Long, who has resigned.

* * *

Announcement was made on July 7 that **Dr. William T. Hudspeth** would become associated with the

Municipal Bonds Have a Prime Security

Have you ever stopped to analyze the basic security of a municipal bond? This can be done most easily by following the general procedure in the issuance of municipal bonds. Let us assume a Minnesota School District desires to issue bonds to provide money for the construction of a new school building.

A School District is an instrumentality of the State, administered by a Board elected by the voters within the territorial limits of the District. Once the Board has determined the necessity of a new school building and an estimate of the cost involved is known, an election is held on the question of issuing bonds.

If the election carries by the necessary majority, then the Board may sell the bonds and pledge as security the full faith and credit of the taxing district (the School District). At the time the bonds are issued the Board certifies a tax levy to the County Auditor to be levied during each of the years the bonds are outstanding which levy will be made automatically unless sufficient funds are on hand from other sources.

Funds derived from the collection of taxes for bonds and interest must be used only for that purpose and, should they prove to be insufficient, any other available funds must be used to meet bond payments. If necessary, additional taxes must be levied. There is no limitation on the taxes which may be levied on any taxable property based on its assessed valuation for Minnesota School Districts but the total school district taxes in any one year may not exceed an amount equal to $40 per capita of all persons residing in the District.

Taxes levied to pay principal and interest on these bonds are collected at the same time and as a part of other property taxes against all taxable property, both real and personal, in the District. These taxes have priority and come ahead of any other lien or claim on this taxable property. It is no exaggeration, therefore, for the holder of one of the School District's bonds to drive through the District, past the dairy and grain farms, past the factory and production plants in the community, along the railroad track, past the stores, bank, homes, etc., and say, "All of this property is security for my bond."

We shall be pleased to send you information and descriptive circulars of municipal bonds we are currently offering.

Madison Clinic in Madison on July 14. A graduate of Cornell University, Dr. Hudspeth served his internship and a one-year residency in surgery at Syracuse University Medical Center. He then studied surgery for one year at the University of Minnesota and for two years at Swedish Hospital, Minneapolis. He served in the Army for three years.

* * *

After completing his third year of postgraduate medical study at Methodist Hospital, Dallas, Texas, **Dr. George T. Van Rooy** returned to Thief River Falls on July 3 and resumed his affiliation with the Bratrud Clinic there.

The December Clinical Session of the AMA, which was to have been held in Denver, will be held instead in Cleveland on December 5 through 8. Labor trouble in the building of the Denver Auditorium, with work stoppage, forced the change in plans. The local committee on arrangements had prepared an excellent program, which will now have to be scrapped and new committees appointed and a new program arranged.

PHYSICIANS HEALTH ASSOCIATION

48 years under the same management
400 First National Bank Bldg., Omaha 2, Nebr.

at 211 Midway Medical Arts Building, Saint Paul. The two new associates are **Dr. Barnard Hall** and **Dr. John B. Coleman.**

Dr. Hall, a graduate of the University of Oregon Medical School in 1942, interned at the University of Wisconsin. During his service in the Army he was associated with the Army School of Roentgenology and recently was a fellow in radiology at the University of Minnesota.

Dr. Coleman, who graduated from Northwestern University Medical School in 1943, interned at the Evanston Hospital. During his Army service he was at the Army School of Roentgenology, and from 1946 to 1949 he served a fellowship in radiology at the University of Minnesota. During the past year he has been associated with Dr. Richard Schatzki at Cambridge, Massachusetts.

* * *

Dr. and Mrs. E. P. Frisch, Willmar, sailed from New York on July 8 for a two-month trip through Europe. Dr. Frisch planned to attend the International Medical Congress in France late in July. The couple expected to return home on September 15.

* * *

Dr. Paul Carpenter, a staff member of the Oliver Clinic in Graceville, left on June 28 for Kansas City to begin a four-year residency in surgery at St. Margaret's Hospital.

* * *

The Board of Trustees and the AMA Council on Foods and Nutrition selected **Dr. Fuller Albright,** associate professor of medicine at Harvard Medical School, as the 1950 recipient of the Joseph Goldberger award in clinical nutrition.

The award was established in 1948 for the purpose of honoring physicians who have contributed importantly to the world's knowledge of nutrition. In addition, the award is made annually by the AMA to stimulate and encourage research in the field of nutrition. The award, which consists of a gold medal and $1,000 in cash, will be made at a meeting some time in the fall. The meeting site has not yet been selected.

Dr. Albright, who is connected with the Massachusetts General Hospital, received his medical degree from Harvard in 1924. He is best known for his studies of human metabolism as influenced by the endocrine glands. He studied the parathyroid glands and their influence on the body's use of calcium. He devoted most of his time to studying mineral metabolism.

* * *

The use of German physicians to help solve the medical staff shortage in Minnesota mental institutions was proposed by **Dr. S. Alan Challman,** Minneapolis, following his return from Europe early in July. Dr. Challman, who went on a sixty-day tour of Germany as a consultant to the Army Surgeon General, said that some German physicians are now assisting Americans in many Army hospitals in Germany. He stated that they would all like to come to the United States and that they probably would be of great use in our mental hospitals. "I hope to present to Governor Youngdahl a suggestion that Minnesota might change its medical licensing regulations enough to admit these men and perhaps limit them to practice in specific hospitals," he said. Dr. Challman is a clinical associate professor in psychiatry at the University of Minnesota.

* * *

Dr. George W. Snyder, Saint Paul, director of social hygiene for the Saint Paul Department of Education, has been named a trustee of the American Legion Hospital Association of Minnesota. The association arranges for the care of needy veterans and their dependents at the Mayo Clinic.

* * *

It was announced on July 8 that **Dr. and Mrs. Howard Kaliher** had decided to leave Pelican Rapids to travel and to take up duties in foreign countries. Their main plan, it was stated, was to locate in northern India and do mission work.

* * *

Dr. and Mrs. O. T. Clagett and **Dr. and Mrs. L. M. Eaton**, Rochester, returned home on June 27 after a three-month trip through the Pacific area. During the journey the two physicians spoke before groups in several cities in Australia, New Zealand and Hawaii.

* * *

Dr. Frances King-Salmon, resident physician at Glen Lake Sanatorium, was named a fellow of the American Medical College of Chest Surgeons at a meeting of the organization in San Francisco early this summer.

* * *

Dr. Donald C. Balfour, emeritus staff member of the Mayo Clinic, was awarded an honorary fellowship in the Royal College of Surgeons of Edinburgh in June. He delivered a series of lectures at the University of Edinburgh as part of his three-month tour of European cities.

* * *

Dr. John Bussman, formerly of St. Peter, was married in Minneapolis on June 17 to Miss Muriel Koenck, formerly of Wall Lake, Iowa. A graduate of the University of Minnesota Medical School, Dr. Bussman is now completing a fellowship in pediatrics at the University.

* * *

Wadena acquired a new physician when **Dr. James H. Kelly**, formerly of Saint Paul, arrived in Wadena on June 30 to become an associate of the Davis Clinic. Dr. Kelly, a graduate of the University of Minnesota Medical School, served his internship at Ancker Hospital, Saint Paul. He has completed a general residency at St. Luke's Hospital, Saint Paul, and a residency in internal medicine at Ancker Hospital.

* * *

Dr. and Mrs. L. G. Idstrom and family, of Wayzata, sailed on July 12 for an extensive tour of Europe. While in England, Dr. Idstrom planned to attend the International Radiological Congress being held in London.

Dr. Clarence Arlander, Minneapolis, announced late in June that, beginning July 1, **Dr. Carl Olson** would be associated with him with offices at 2300 Central Avenue. A graduate of Northwestern University Medical School, Dr. Olson interned at Minneapolis General Hospital.

* * *

Dr. Alois M. Scheidel, formerly of Minneapolis, has moved to Cokato and become a staff member of the Cokato Hospital.

* * *

Public contributions to the **Minnesota Heart Association Fund** during the 1950 campaign totaled $99,649, it was announced on July 11. Of the amount, $41,000 was contributed by Hennepin County.

* * *

Dr. William A. Bessesen, Minneaolis, sailed from New York on July 13 for Buenos Aires to attend the seventh biennial assembly of the International College of Surgeons, held August 1 to 7.

* * *

Dr. Charles Slocumb, Rochester, was elected president of the American Rheumatism Association at its annual meeting in San Francisco on June 24.

* * *

Dr. Arnold A. Anderson opened offices for the practice of medicine in Hopkins on July 1. A graduate of the University of Minnesota Medical School in 1943, Dr. Anderson interned at the San Diego County Hospital, California, and then completed a residency in internal medicine there. He served in the Army from 1945 to 1947. He recently completed three years of pediatric training at the Mayo Clinic.

* * *

Four hundred persons attended a reception honoring **Dr. I. G. Davis** of Rushford on July 7. The reception, which was given by Dr. R. V. Williams, Rushford, was to pay tribute to Dr. Davis on the occasion of his retirement from active practice. Dr. Davis practiced in Rushford for thirty-one years. His practice has been taken over by Dr. M. J. Woltjen.

* * *

Dr. Henry P. Staub, Minneapolis, received a master's degree in pediatrics from the University of Minnesota in June. A graduate of the University of Illinois, Dr. Staub has been a resident of Minneapolis for ten years. For the past two years he has been studying pediatrics at University and Minneapolis General Hospitals.

* * *

Ten young physicians, all war veterans and all with University of Minnesota postgraduate training, are building a $150,000 medical clinic in **St. Louis Park** (Minneapolis).

The large, one-story, modern building is expected to be ready for occupancy in 1951. The clinic will be able to offer the services of specialists in internal medicine, surgery, obstetrics and gynecology, and otorhinolaryngology. Most laboratory procedures will be handled by technicians in the building.

The group includes Dr. Richard Webber, Dr. Arnold Anderson, Dr. Donald Freeman, Dr. Alex Barno, Dr. Robert Green, Dr. David Anderson, Dr. John LaBree, Dr. Rovert Giebink, Dr. Sewell Gordon, and Dr. Wyman Jacobson.

* * *

Dr. Ellery M. James, formerly pathologist at St. Joseph's Hospital, Saint Paul, has opened a medical laboratory at 657 Lowry Medical Arts Building, Saint Paul.

* * *

Dr. Samuel Miller has moved to Albert Lea to become radiologist at the Naeve Hospital. He recently completed a residency in radiology at the University Hospitals.

HOSPITAL NEWS

The Zumbrota Community Hospital was officially dedicated at ceremonies held on June 30. The dedicatory address was delivered by Dr. Viktor Wilson, Rochester. Open house was held at the hospital on July 2.

BLUE CROSS-BLUE SHIELD NEWS

Minnesota Blue Shield paid 4,625 claims during May, 1950 and 4,788 claims during June, 1950. The May payment totaled $189,611.93, the June payment $184,427.37. Total payments to participating doctors for May covering 4,420 claims was $179,403.50. The June total to participating doctors was 4,601 claims in the amount of $176,052.

Minnesota Blue Shield was among the seven plans adding more than 50,000 new members during the first three months of 1950 and have the second greatest increase in percentage of population enrolled. By May 31, an additional 30,774 Minnesotans had enrolled in Blue Shield making a net growth of 85,499 new subscribers in 1950 and a total enrollment of 346,000 as of May 31, 1950. The 69 member Blue Shield Medical Care Plans throughout the country reported a net growth of 975,872 new members bringing the total membership to 13,276,597; the ten non-member plans reported a net gross of 178,157 new members and a total membership of 2,106,213 making a combined membership of 15,382,810 in the 79 Medical Care Plans as of March 31, 1950.

In checking the payment during June of 1950, the bulk of payments were for cases initiated during May; however, the records still show a considerable number of cases outstanding from the last half of 1949 and also the first quarter of 1950. The Blue Shield office attempts to contact the doctors on these old unfinished cases; however, it would expedite the payment of all such cases if each doctor's office would submit a report on any and all outstanding Blue Shield claims. In so far as possible, the Blue Shield office would like to have all Blue Shield cases reported within thirty days after service is initiated. The cooperation of the doctor in sending Medical Service Report forms to this office at the earliest possible opportunity would assist in attaining this objective.

The Blue Shield office receives an ever-increasing number of calls from patients who are not quite clear as to whether or not the payment by Blue Shield has been deducted from the statement which the doctor sends to his patient. It is suggested that in so far as possible all monthly statements show the net amount payable less a credit for the Blue Shield allowance. This minor bookkeeping detail will eliminate many questions which I am sure the doctor's office receives and also give the Blue Shield subscriber a better idea as to the value of his Blue Shield on each doctor bill.

Enrollment of participating doctors with Minnesota Blue Shield totals 2,660 as of the end of June. The Minnesota Blue Shield is still attempting to attain as complete participation of the doctors with the Medical Service Plan as is possible. Any of you who have not as yet enrolled with this Voluntary Medical Care Plan are requested to do so at your earliest opportunity.

BOOK REVIEWS

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical Libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

CLINICAL APPLICATIONS OF SUGGESTION AND HYPNOSIS. William T. Heron, M.A., Ph.D. Professor of Psychology, University of Minnesota, Minneapolis. 116 pages. Price, $3.00, cloth. Springfield, Illinois: Charles C Thomas, 1950.

PRACTICAL PHYSIOLOGICAL CHEMISTRY—Twelfth Edition. By Philip B. Hawk, Ph.D., President, and Bernard L. Oser, Ph.D., Director, Food Research Laboratories, Inc., New York; and William H. Summerson, Ph.D., Associate Professor of Biochemistry, Cornell University Medical College, New York. 1323 pages. Illustrated. Price $10.00. Philadelphia: The Bakiston Company, 1947.

When an average person tries to review a book on Physiological Chemistry, he must expect to give only a general idea of the usefulness of such a book to his readers. The detailed material presented in this book is styled just as in the previous editions. Some of the newer advances in medicine are included in the material presented. Probably the newest, discussion of the isotopes as used in research when elements are tagged to determine their physiologic life in the body.

The chapter dealing with vitamins and deficiency diseases is especially good and I would suggest that it be given careful attention.

A particularly valuable discussion is that dealing with the experiments on steroid hormones.

The latter chapters deal with antibiotics which also indicates the current thought that is carried throughout the book. In general, I would say that this twelfth edition is a definite improvement over the previous ones and should be in every medical library.

Joseph M. Ryan, M.D.

BREAST DEFORMITIES AND THEIR REPAIR. By Jacques W. Maliniac, M.D., Clinical Professor of Plastic Reparative Surgery and Associate Attending Plastic Reparative Surgeon, New York Polyclinic Medical School and Hospital, New York City; Attending Plastic Surgeon, Sydenham Hospital; Diplomate, American Board of Plastic Surgery. 193 pages. Illus. Price, $10.00. New York: Grune & Stratton, 1950.

Written with the purpose of presenting a complete and accurate account of the present status of mammaplastic surgery, this monograph should go far towards a better understanding of the problems associated with breast deformities and to encourage their repair. In a field understood well by only a few specialists in plastic surgery, it will be an invaluable reference for those encountering these problems in every day practice.

The author has made an exhaustive study of the historical backgrounds of mammaplasty, the misconceptions as well as facts of breast anatomy and blood supply, the essential elements of repair of deformities, and the numerous procedures designed to correct them. Not only are his own techniques presented in detail but also those of other surgeons past and present who have contributed to this interesting field. Numerous detailed drawings and convincing photographs supplement the text.

This book deserves a place on the shelves of all reference libraries as well as those who attempt the surgical treatment of these deformities.

Edward W. Sickels

AMUSING QUOTATIONS FOR DOCTORS AND PATIENTS. Edited by Noah D. Fabricant, M.D. 149 pages. Price $3.00. New York: Grune and Startton, Inc., 1950.

As its title indicates, this book is a collection of quotations about virtually every subject that is remotely related to medicine. The subjects run from Accidents to Youth, and include such diverse topics as Buttocks, Fees, Measles, Nurses, and Snoring. Though many of the quotations are bitter, cleverly worded attacks on the practice of medicine, most physicians should derive a

Attending Psychiatrists

Dr. L. R. Gowan **Dr. C. M. Jessico**
Dr. J. E. Haavik **Dr. L. E. Schneider**

large number of smiles and chuckles while thumbing through the book. The contents of this volume would probably be most useful to physicians who do a considerable amount of public speaking.

A few samples will illustrate, better than any review, what the book is like:

Mark Twain on the Gastrointestinal Tract: "Only presidents, editors, and people with tapeworms have the right to use the editorial 'we.'"

Henrik Ibsen on Antivisisection: "It is inexcusable for scientists to torture animals; let them make their experiments on journalists and politicians."

Ambrose Bierce on Diagnosis: "A physician's forecast of disease by the patient's pulse and purse."

George Bernard Shaw on Experts: "No man can be a pure specialist without being in the strict sense an idiot."

William Osler on the Art of Medicine:`"Look wise, say nothing, and grunt."

M. A. Perlstein on Pediatricians: "Pediatricians eat because children don't."

Morris Fishbein on Tobacco: "He is an expert surgeon, brilliant pathologist, and an uncanny diagnostician, but he is somewhat rusty on advanced cigarette testimonials."

—J.H.L.

THE MERCK MANUAL OF DIAGNOSIS AND THERAPY: A SOURCE OF READY REFERENCE FOR THE PHYSICIAN. 8th ed. 1592 pages. Regular edition, $4.50: Thumb-Index edition, $5.00. Rahway, N. J.: Merck & Co.; Inc., 1950.

Ten years have elapsed since a new edition of the *Merck Manual* has appeared; and, now, following extensive preparation, the eighth or Golden Anniversary, edition has been published.

The Manual needs no introduction to those who have been in practice for some time; but to the newcomer in the practice of medicine a few words of explanation may be in order. The Manual is a convenient handbook of diagnosis and treatment of a multitude of conditions in all branches of medicine and surgery.

Each disorder is briefly defined, and then follows a concise discussion of its etiology, incidence, pathology, symptoms and signs, diagnosis, prognosis and treatment. At the end of each section into which the chapters are grouped are the prescriptions most commonly used in the disorders discussed in that section.

For example, examine the section on the Ear, Nose and Throat. The material is intended primarily for the general practitioner and is a helpful aid regarding the most common ear, nose and throat conditions. In this section is presented, first, the frequent diseases of the external ear, namely, furunculosies, otomycosis, cerumen, foreign bodies, trauma, herpes zoster, impetigo contagiosa, and tumors; then, of the middle ear diseases, such as myringitis, eustachian salpingitis, otitis media and mastoiditis; and of the inner ear, including labryinthine disease and otosclerosis. Tinnitus and deafness are dealt with as far as time and space will permit.

The commonest disorders of the external nose are summarized in one paragraph with suitable cross references to other pages. Rhinosclerma is the only condition here described. As to the internal nose, conditions of the septum, i.e., deviation, ulcer and perforation, are dealt with. Rhinitis (acute, allergic, chronic and atrophic) and polyps complete the discussion on nasal passages. The paranasal sinuses with their acute and chronic disturbances are handled adequately. Nasal trauma, fractures and foreign bodies are mentioned; and epitaxis is given ample space.

Pharyngeal diseases, including tonsillitis, peritonsillar abscess, hypertrophied adenoids, acute and chronic pharyngitis, are next in order. Then, in logical sequence, follows laryngeal problems, i.e. acute and chronic laryngitis, tuberculous and luetic laryngitis and, also, the general complaint of hoarseness. Last but not least, there is a full list of common useful prescriptions for ear, nose and throat problems.

Some one hundred pages of the Manual are devoted to common procedures and routines and to such useful bits of information as the essential contents of the physician's bag, a list of alternative proprietaries, and conversion formulas. A good index facilitates the use of this handy, ready reference tool.

E. L. Bauer, M.D.

AMA DIRECTORY—Eighteenth Edition. A Register of Physicians. Edited by Frank V. Cargill. 2913 pages. Price $25.00. Chicago: American Medical Association, 1950.

The eighteenth edition of the Directory of the American Medical Association is now available after three years of work. This is the first edition since 1942. The

SERVICE BROWN & DAY INC SAINT PAUL U.S.A. QUALITY

For

Professional Supplies

and

Service

BROWN & DAY, INC.

St. Paul 1, Minnesota

long interval was caused by the war and printing difficulties.

The new directory contains 2,913 pages, and lists information on 219,677 physicians in the United States, its dependencies, and Canada. It also lists American graduates and licentiates located temporarily abroad. Since the 1942 directory, thousands of changes of address have been made; 51,984 names have been added, and 28,242 names dropped from the book on account of death or for other reasons.

In the 1942 directory, the total number of physicians listed in the United States was 180,496; in the 1950 edition, the number is 201,277, or a gain of 20,781, an average yearly gain of 2,598 during the last eight years.

The Pacific States show the largest increase in physicians, the Atlantic and Great Lakes States a moderate incerase, and the West Central States the greatest losses. California leads in the number gained, with 16,688 physicians in 1950 as compared with 12,365 in 1942, a gain of 4,303. New York state shows a gain of 2,284, Texas a gain of 772, Pennsylvania 704, Florida 634 and Massachusetts 603.

For the first time, postal zone numbers appear after the residence and office addresses of physicians in cities where they are required by the Post Office Department. A new feature is the inclusion of data on the World Medical Association.

The directory costs $25. Orders can be placed by writing to Frank V. Cargill, Directory Department, American Medical Association, 535 North Dearborn St., Chicago 10, Illinois.

MEDICAL ECONOMICS

(Continued from Page 818)

Liberty Termed "Perishable"

Believing that liberty far outshines security, if a choice is required, James A. Farley nevertheless believes that liberty and security are compatible. He states:

> "We have got to get rid of the fixed idea that liberty is imperishable on our continent. If the choice is given to us of liberty *or* security, we must scorn the latter with the proper contempt of free men who know that liberty *and* security are not incompatible in the lives of honest men."

Poets, too, have carved verses dedicated to stopping the spoilage of this perishable, commodity, human liberty. For instance, the words of Walt Whitman:

"To the States or any one of them, or any city of
the States, *Resist much, obey little.*
"Once unquestioning obedience, once fully enslaved,
"Once fully enslaved, no nation, state or city of this
earth ever afterward resumes its liberty."

MINNESOTA ACADEMY OF MEDICINE

TREATMENT OF FRACTURES

(Continued from Page 821)

were in traction with fractures of the femur. I had one trained assistant, the other men who were helping me were gynecologists, obstetricians and pediatricians. Naturally we wished that we had the Kuntchner nails at that time because the treatment and responsibility of 187 fracture cases in traction was rather tremendous. Dr. Cole has covered this subject very thoroughly and evaluated it very properly. It is a procedure which has merit and I am very glad that he ended his presentation with one or two complications. I have seen many patients and I have seen many complications. I have seen osteomyelitis, soft tissue infection, non-union, delayed union, broken nails and nails protruding from the wound because the surgeon wasn't able to drive it within the distal fragment or remove it at the time of operation. I mention these many complications not to condemn the procedure because I agree that it is a valuable procedure; I mention them merely to emphasize the importance of fracture training. When there are emergencies and great numbers of fractures, we should be prepared with fracture teams, so that they can be treated with internal fixation without complications so that they will not require many months of bed treatment. Many phases of this problem are worthy of discussion but, because of the time, I will not continue.

Dr. Verne C. Waite, of Honolulu, Hawaii, then gave a talk (by invitation) on "General Surgical Practice in Hawaii."

The meeting was adjourned.

Wallace P. Ritchie, M.D., *Secretary*

MEAD'S
MEAD JOHNSON & CO.
EVANSVILLE, IND., U.S.A.

FOR ALMOST FOUR DECADES physicians have recognized the merits of infant-feeding formulas composed of cow's milk, water and Dextri-Maltose*.

In LACTUM and DALACTUM, Mead's brings new convenience to such formulas—for LACTUM and DALACTUM are prepared for use simply by adding water.

LACTUM, a whole milk formula, is designed for full term infants with normal nutritional needs. DALACTUM is a low fat formula for both premature and full term infants with poor fat tolerance. Both are generous in protein.

"Premarin"—a naturally occurring conjugated estrogen which has long been a choice of physicians treating the climacteric—is earning further clinical acclaim in the treatment of functional uterine bleeding.

The aim of estrogenic therapy in functional uterine bleeding is to bring about cessation of bleeding, and to produce subsequent regulation of the cycle. Once hemostasis is achieved, the maximum daily dosage of "Premarin" must be continued to prevent recurrence of bleeding. This schedule forms part of cyclic estrogen-progesterone treatment for attempted salvage of ovarian function.

While sodium estrone sulfate is the principal estrogen in "Premarin," other equine estrogens...estradiol, equilin, equilenin, hippulin...are probably also present in varying amounts as water-soluble conjugates.

An "estrogen of choice for hemostasis is 'Premarin' in tablets of 1.25 mg. ... The usual dose for hemostasis is 2 tablets three times a day. If bleeding has not decreased definitely by the third day of treatment the dosage level may be increased by 50 per cent."*

*Fry, C. O.: J. Am. M. Women's A. 4:51 (Feb.) 1949

"PREMARIN"®

Estrogenic Substances (water-soluble)
also known as Conjugated Estrogens (equine)

Four potencies of "Premarin" permit flexibility of dosage: 2.5 mg., 1.25 mg., 0.625 mg., and 0.3 mg. tablets; also in liquid form, 0.625 mg. in each 4 cc. (1 teaspoonful).

Announcing new CUSTOM-BUILT

the 500 MA vertical control

AGAIN, Keleket sets the pace with a money-saving development. NOW—ALL UNITS—200 MA, 300 MA and 500 MA use the SAME TRANSFORMER and CONTROL which can be produced at a savings... passed on to you!

By standardizing many parts of the world-famous Multicrons, Keleket is able to offer custom-built units . . . which fit your individual requirements exactly . . . at most attractive prices.

Every unit is equipped with the same functionally designed cabinet, finished in handsome Kelekote.

This unit may be installed permanently, even in a wall, with no worry about alterations . . . should your future technic requirements call for the higher capacity Multicrons.

All units . . . 200 MA, 300 MA and 500 MA... include the features which have made Keleket Multicron Controls so popular with radiologists . . . for flexibility, convenience and accuracy.

the 200 MA vertical control

The controls are rated as follows:

DIAGNOSTIC

200 MA unit—125KVP at any MA from 25 to 200

300 MA unit—125 KVP at any MA from 25 to 300

500 MA unit—125 KVP at any MA from 25 to 500

THERAPY

All units—140 KVP to 10 MA

An optional Photo-Timer and Photo-Timing pushbutton control can be mounted in the vertical controls. Unit is so designed and engineered that only minor alterations are required to effect increased capacity and timer changes.

Telephone or write for complete details

BIRDS *are descended from reptiles*

and, like these ancestors, they do not perspire: but many a doctor is, as they say, "sweating blood" over his collections. (Or, if he isn't, his secretary is.)

Leaving ornithology and herpetology out of it and getting down to sheer economics the fact is that while we know nothing about medicine we do know ACCOUNTS RECEIVABLE. With your permission we would like to deal with your secretary—or with you if you have the time — and take off your hands all accounts more than six months past due. One hour spent plucking those accounts from your ledger now and turning them over to

PROFESSIONAL CREDIT PROTECTIVE BUREAU

for deft, tactful, conscientious, firm and effective approach and consummation of collection may save you hundreds of dollars, hours of distraction and a tremendous amount of consideration as to whether or not you are going to sacrifice any goodwill. These are days of tension. Old accounts aren't going to be any easier to gather in during the winter than now or early fall, maybe not as easy. It's time to take action.

This is a personalized, completely proved procedure. We have no black magic, no inspired touch, but what we do have is a know-how on professional debits, a background in getting in the outstanding, a technic of careful analysis of each account, a knack of taking it over as your representative in the same decent way in which you would function. The returns flow to you direct and not through us. This kind of faithful service and understanding treatment has brought in hundreds of thousands of dollars to other practitioners and we would like very much to put ourselves at your disposal and become one of the effectives of your office. Send us 35 accounts which we will handle for $35; 105 accounts for $100: we to receive 20% for all monies paid to you. AND THE ACCOUNTS CAN BE "TOUGH ONES," TOO!

Tear off the corner of this page and fill in your name and address. We will send you the required forms and a written guaranty. And be assured that we do all the work.

AUREOMYCIN
CRYSTALLINE

for complications following Acute Infections in Childhood

Now is the season for children to enter upon their scholastic labors, and in most communities to receive either primary, or booster, immunization against several of the common childhood infections. Reliance must be placed upon antibiotics to control the secondary invaders which may follow these infections. Pediatricians are increasingly turning to aureomycin for this purpose, because of its wide range of activity against the common Gram-positive and Gram-negative organisms.

Aureomycin is also indicated for the control of the following infections:

Acute amebiasis, bacterial infections associated with virus influenza, bacterial and virus-like infections of the eye, bacteroides septicemia, boutonneuse fever, brucellosis, chancroid, Friedländer infections (Klebsiella pneumonia), gonorrhea (resistant), Gram-negative infections (including those caused by some of the coli-aerogenes group), Gram-positive infections (including those caused by streptococci, staphylococci, and pneumococci), granuloma inguinale, *H. influenzae* infections, lymphogranuloma venereum, peritonitis, pertussis infections (acute and subacute), primary atypical pneumonia, psittacosis (parrot fever), Q fever, rickettsialpox, Rocky Mountain spotted fever, sinusitis, subacute bacterial endocarditis resistant to penicillin, surgical infections, tick-bite fever (African), tularemia, typhus and the common infections of the uterus and adnexa.

Capsules: Bottles of 25, 50 mg. each capsule. Bottles of 16, 250 mg. each capsule.
Ophthalmic: Vials of 25 mg. with dropper; solution prepared by adding 5 cc. of distilled water.

For Safe Symptomatic Relief During the "*Late*" Hay Fever Season

There are good reasons why many allergists consider "late" hay fever a more serious threat than the Spring and Summer types of seasonal allergy: ragweed pollens cause a greater incidence of hay fever than all other pollens combined; more pollens are in the air during the ragweed season than at any other time; and since "the United States is the favorite habitat of ragweed, it has the dubious distinction of harboring more hay fever victims than all the rest of the world together."[1]

Fortunately, more and more patients each year are enjoying the therapeutic benefits of Neo-Antergan® Maleate. Because of its safe and strikingly effective action in relieving the distressing symptoms of allergy, Neo-Antergan has become a favorite antihistaminic with physicians and patients—*in every season of the year.*

Neo-Antergan is advertised exclusively to the medical profession. Your patients can secure its benefits *only through your prescription.*

Neo-Antergan Maleate is stocked by your local pharmacy in 25 mg. and 50 mg. tablets. Complete information concerning its clinical use will be sent on request.

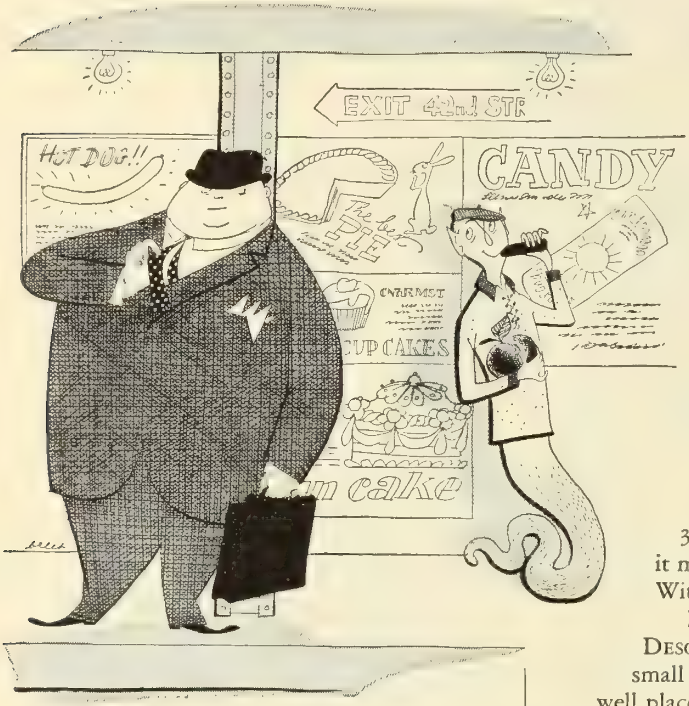
COUNCIL ACCEPTED

When all signs point to *forbidden* foods...



● When he's hungry—when his gourmand's soul begins to rebel against the dull, plodding pace of the reducing diet—this is when physician and patient alike welcome a relatively safe, effective central stimulant. ● With Desoxyn Hydrochloride, small doses are sufficient to produce the desired cerebral effect—anorexia, elevation of mood and desire for activity—with relative freedom from undesirable side-effects. Smaller dosage is possible because, weight for weight, Desoxyn is more potent than other sympathomimetic amines. Other advantages are Desoxyn's faster action, longer effect. One 2.5-mg. tablet before breakfast and another about an hour before lunch are usually sufficient. A third tablet may be taken about 3:30 in the afternoon, but after 4 p.m. it may cause insomnia in some persons. With small oral doses, no pressor effect has been observed. ● Why not give Desoxyn a trial? Unless contraindicated, small doses are harmless. And small doses well placed may mean the difference between success and failure in the outcome of the reducing regimen. **Abbott**

A Real American Breakfast

That a nutritious breakfast providing generous amounts of high quality protein prevents late morning hypoglycemia has been amply demonstrated. As shown by Thorn and co-workers,[1] and later confirmed by Orent-Keiles,[2] ". . . breakfast high in protein and low in fat and carbohydrate was followed by an improved sense of well-being and no symptoms of hypoglycemia."

Meat for breakfast—ham, sausage, bacon, breakfast steaks—is an appetizing means of increasing the protein content of the morning meal. Its biologically complete protein contains all essential amino acids, and serves well in complementing less complete proteins from other sources. Furthermore, muscle meat is an outstanding source of B complex vitamins and of iron.

The Seal of Acceptance denotes that the nutritional statements made in this advertisement are acceptable to the Council on Foods and Nutrition of the American Medical Association.

not "food allergy"... but "casein allergy"

Inability to tolerate milk casein is one of the most frequent causes of allergy in infants. Casein allergy, as manifested by such symptoms as gastrointestinal upsets and atopic eczema, may follow the ingestion of any animal milk. In true casein allergy, all animal milks, including goat's milk, must be avoided.

In such cases Mull-Soy provides the answer. Mull-Soy compares closely with cow's milk in nutritional values of protein, fat, carbohydrate, and minerals.

Mull-Soy is a liquid, pleasant-tasting, homogenized, stable (vacuum packed) food, high in unsaturated fatty acids.

MEDICAL PRACTICE ON LEVEL FOUR

F. J. ELIAS, M.D.
Duluth, Minnesota

THE ninety-seventh annual meeting of the Minnesota State Medical Association is a significant occasion in significant times—but it is obvious now to all of us that history has not stopped long enough to allow us to catch our breath.

We are on level four of our cultural development and, in many ways, we are unable to cope with the discoveries that led us to levels two and three.

"What is level four?" you may ask. "How did we get there and where is it?"

Customarily we reckon time in years or centuries. We may stop and reflect that we are now halfway through the twentieth century. But the students of cultural growth tell us that we have developed by stages . . . according to the time it has taken us to discover that we could turn the sun and the fossilized products of the earth and, finally, matter, mysterious, formulae-ridden matter, into energy for use in supplying our needs.

Our struggles to capture free energy have brought us to level four, the here and now. It's the mutable, shifting, disconcerting, challenging present that alternately fills us with optimism and despair. It is a state of mind and a state of culture. It is—and not incidentally—the level on which we are trying to keep our discoveries from destroying us.

For it is inevitably true that our possibilities have outdistanced our needs, and our knowledge is too far ahead of our reason.

Medical science has established its own peaks and plateaus on this level four of atomic living. We know that the foundations for medical advances were laid, in many cases, before the first atomic explosion catapulted us onto level four. But they were waiting to come into fruition. Now we have the dual prospect of longer and longer life or immediate mass suicide. Will the life-lengthening discoveries of science be cancelled out by the life-extinguishing discoveries of science? Or will man's greater maturity, that longer life is bringing, be able to shift the direction of our discoveries into channels of greater, more productive and pleasanter living?

Medicine must assume its responsibilities in this crisis of scientific, sociological and economic development, if the outcome is to be a fortunate one.

And to gauge those responsibilities, we must look back, across the years, to a time when life was simpler because so many of its consequences could safely be termed "inevitable," and so many of its problems, "insoluble."

Our general knowledge and, more especially, our scientific knowledge have changed our lives more in the past twenty years than in the previous fifty—more in that fifty years than in the previous two hundred. We may then, for all practical purposes, take the first half of the twentieth century as our quantity X.

In that time we have reaped the rewards of the germ theory of disease, for, with chemotherapy and public sanitation, we have all but mastered many disease micro-organisms—as significant a development as stone age man's successful battle with external organisms—the animals that preyed upon him until, with superior intelligence, he outwitted them.

Presidential address given at the annual banquet of the Minnesota State Medical Association, Duluth, Minnesota, June 13, 1950.

The doctor of yesterday, who hurried to his patients with about equal amounts of sympathy and science, was welcomed by the anxious families, although they knew his limitations almost as well as he knew them, himself. But he was there, a friend and confidante, who yielded with them to the inevitable, when his meager science failed.

But the doctor of today and, with greater truth, the doctor of tomorrow, is welcomed by the anxious families because he is the master of a mysterious science, a twentieth century worker of miracles who is not expected to yield, but to conquer the inevitable.

Thus, our responsibilities as doctors have become greater . . . the further we crowd back the barriers of disease and death, the further we are expected to push them. And, at the same time, more is expected of us as interpreters of this science, as leaders in the thought patterns that are emerging from scientific discoveries that constitute the very core of our civilization.

In administering the heady potion of longer living, we have incurred an obligation of helping to direct the use of these added years and to form logical answers to the questions that stand between man and a clear title to his new longevity.

Science has multiplied upon itself, like the mold of penicillin develops in a culture tube. Discovery has spawned upon discovery. One man has supplied the clue to another's experiment and that, in turn, has led to yet another development . . . as exemplified by Dr. Banning's idea for insulin, prompted by reading an article by Dr. Barron of Minneapolis—or the investigations of Whipple, which were followed by the work of Minot, Murphy and Castle and finally of Cohn, and resulted in liver extract. And now we have a further development in pernicious anemia therapy—vitamin B_{12}—which, injected in such infinitesimal amounts as one microgram daily, will cause a remission in this once-fatal disease. Fleming, followed by Florey, was, of course, responsible for penicillin, now being produced at the rate of something like four thousand billion units per month in the United States.

And scientific discoveries have generated new forms of application. By continuous and flexible interpretations of medical science, Minnesota, for instance, has cut its tuberculosis death rate from 106.4 per 100,000 in 1900 to 13.8 in 1949.

Duluth represents a striking example of progress in sanitation. In the early years it had the highest mortality rate in the cities of its class, as a result of typhoid fever. For a number of years now it has occupied a distinctive position in its freedom from this disease.

Within the span of my own life, I have observed medical science in headlong progress. I remember the ponderous static machine for the development of an unstable potential to energize a similarly unstable gas-filled x-ray tube, acquiring with these, if we were fortunate, an exposure on a glass plate comparable to that of Roentgen's. Similar in antiquity was the apparatus used in an assignment with the British Expeditionary Forces in the First World War, with equipment energized by an induction coil and, for interruptions of the current, electrodes separated in a champagne bottle! In the field of chemotherapy, the first administration of salvarsan was attended by procedure and preparation of major surgical proportions. Likewise, precisely prepared Dakin's solution was once accepted as the final answer to the control of sepsis in wounds. And there has been an ebbing of lay and medical confidence in the prevention of colds by antihistamines similar to the rejection of chlorine inhalation.

It may sound pretentious or provincial to say this, but, in Minnesota, the problems relating to science are perhaps at a high point in the nation. For here we have concentrated so deeply on their primary phases. I have recounted to you our progress in a few special fields of disease. Minnesota has distinguished itself, medically, through the endeavors of such men as Dr. Justus Ohage, who performed the first successful cholecystectomy in America; Dr. Charles Hewitt, pioneer public health worker; Dr. Edward Bockman, who introduced a new type of surgical suture . . . and . . . this is interesting . . . Dr. Hillard Holm, who performed one of the few successful operations separating Siamese twins.

I might remind you, too, of our record-breaking strides in maternal and infant health. And there begins the broad, general problem. We are giving the citizens of our state a head start in health. With low infant mortality figures, with subsequent control over communicable diseases and skilled corrective surgery, we are saving hundreds of persons who will eventually become geriatric problems.

In between, of course, there are broad areas for study and investigation. We need to turn our attention to the patient as a whole, not just as a person suffering from one or more particular maladies. As physicians, we should consider the subject of health as a whole, interesting ourselves in maintaining the individual's health as well as curing him of a disease.

And, too, there is the relatively uncharted field of body chemistry. Why does the body react so strangely to certain hormones, to emotional shocks, to the barely discernible scars of earlier illnesses? When we know, we may be in a position to add another twenty or fifty years to the average life span.

Always, concurrently with the question of "What can we do to extend life?" comes the question of "What will the added years mean?"

We have left the orderly, unalarming scientific patterns of the nineteenth century. We have ceased to regard the lighted areas of science as the only known world . . . instead we spend most of our time in the shadowy patches of near knowledge and the dark of unexplored territory. Our scientific creativity is no longer subject to the old accepted rules. Every day we make new rules for ourselves and, in so doing, we find that many times our previous thinking and experimentation fall into place and another pattern of progress is complete.

But, in the process, just as we have subjected every rule, every supposed truth to restudy, so have we abandoned our belief that progress is necessarily and automatically for the best.

Progress, we observe, is what we make of it. And nowhere is there a better example than in the development of atomic energy. This is progress, yes, but a double-edged progress that can add new dimensions to life or, wielded in reverse, will mean obliteration of all life.

Fissioning atoms are providing medical men with, among other things, such important tools as radioactive tracers, which are being put to use in the fight against cancer and are revolutionizing biology and medical research. The prospects for atomic energy . . . and for the newer explorations in hydrogen . . . are limitless, as we see them now. Or they may be strictly limited by the production of a few highly accurate, infinitely destructive bombs.

With the increased leisure afforded by mechanization and our highly complex industrial civilization, man has supposedly more time to think, to mature, to devote a larger portion of his life to the arts . . . and with the gift of twenty additional years . . . man should be approaching the most exemplary period of human history.

But can we hope for realization of this theory?

Probably not. For hasn't the machine superceded the man? Hasn't science outspaced conscience?

It would appear that our most perplexing and immediate puzzle is one of understanding. We must think our way to the formation of a philosophy sturdy enough and flexible enough to withstand the impacts of level four living.

The comprehension of the man who lives on level four does not seem adequate. He cannot understand even the relatively basic fundamentals of his own existence . . . and the prospect of lengthening life appears terrifying, instead of inviting, to him because he feels that in his later years he may be more vulnerable to the perils of an economically dependent existence.

What can we, as the practitioners and spokesmen of one scientific profession, do to help?

Our duties as physicians at this time are akin to our duties as citizens, it would seem to me.

I will not reiterate our continual responsibilities to become better doctors, to search for and retain the knowledge and skills we need to perform our scientific tasks to the best of our ability. We are inescapably aware of that necessity.

But, it is in the somewhat broader science of human relationships that our obligations sometimes fail to appear in sharp focus and personally applicable. We do not seem to keep an alert attitude in that field . . . to seize, as in medical science, upon an idea, a thought, the dawning comprehension of a truth and to build on it with our own interest and observation and experience; in short, to be as skilled in the epidemiology of sociological and political and economic diseases as we are in the epidemiology of physical disease.

I do not know why we fail so often here, but I assume that it is because we consider our lives well spent if we have given full devotion to our profession. And, while, categorically, we may divide this discipline into prevention, diagnosis and treatment, we do not realize that in the performance of this duty, we are bringing other duties upon ourselves which cannot be postponed or evaded.

First, let's not add to the mystery surrounding science. Let's explain scientific advances in simple terms to our patients. Let's help them to understand their physical selves and to have a general idea of the workings of the human body and, if they are ill, to understand why they are ill, how seriously ill, and what is being done to remedy the damage done by malfunction or micro-organisms.

Through understanding of one science, the people with whom we come in contact will be less unwilling to attempt at least a partial, outline understanding of other sciences that affect and influence their lives. With comprehension of the basic principles of all, will come a more satisfactory adjustment to environment, a firmer stand on the shifting grounds of atomic level four.

Then, we must initiate a re-evaluation of the longer life span that is unfolding for us all. Is it a valuable gift or a Pandora's box that will loose great economic and social evils in the world?

Its potentialities are all for good. Coupled with the expanding educational system—which has enabled 40 per cent of our children to go through high school and 7 per cent through college—longer life should mean better, happier life—more expressive and more complete.

We're being better trained and educated, mechanized industry gives us more leisure and more luxuries for our leisure, and we have a longer time in which to enjoy the good things of the world. Why then, has the assurance of longer life made us so uncertain of our abilities to utilize it?

It is partly because the economically self-sufficient individual has all but disappeared from twentieth century, level four America. We are dependent upon each other, and yet we don't know how to be profitably dependent upon each other.

We are looking for an impersonal leaning post —like the government—fearful of trusting ourselves or each other.

This, then, is the crucial decision point we reach in mid-twentieth century. As physicians, we can and must help to turn the tide of public thinking.

Nor can we rely on the easy, status quo attitude of "peace or plenty or tolerance in *our* time." We must face our problems now . . . for the heritage we pass on should not include the fears and distrust and political shiftings of today.

These are the causes—understanding, and the development of a self-reliant and mutually helpful philosophy—to which we must assign ourselves. We must be just as fanatical about good as the Leninists are fanatical about evil. We must, to paraphrase Lenin himself, find within our ranks people who will devote not just their spare evenings, but the whole of their lives, to the advancement of the principles we have chosen to abide by.

COMPOUND F SYNTHESIZED

A synthesized adrenal hormone chemically similar to cortisone and known as Compound F is proving effective against rheumatoid arthritis, researchers of the Mayo Clinic, Rochester, Minnesota, report.

Announcement of the synthesis of Compound F was made recently by a pharmaceutical company (Upjohn Company, Kalamazoo, Mich.) The company did not say what this synthesis will mean in terms of production, other than to emphasize that the amount of Compound F available does not allow distribution for other than limited clinical testing at the present time.

The report of trial of Compound F against rheumatoid arthritis was made by Dr. Howard F. Polley (one of the group from the Mayo Clinic who originally reported the effects of cortisone and ACTH against the disease) and Harold L. Mason, Ph.D., in the (August 26) *Journal of the American Medical Association.*

"Significant antirheumatic activity was possessed by 17-hydroxycorticosterone (Compound F)," they say. "Minor structural alteration from cortisone occurs in 17-hydroxycorticosterone. Our supply in the last year has permitted trial on one patient, a woman forty-nine years old, whose severe rheumatoid arthritis had been present three years and who had responded well to cortisone and to ACTH.

SURGICAL TREATMENT OF MITRAL HEART DISEASE

IVAN D. BARONOFSKY, M.D.
Minneapolis, Minnesota
and
JOHN F. BRIGGS, M.D.
Saint Paul, Minnesota

THE NEED for a safe technical approach to the surgical treatment of chronic valvular disease of the heart has been recognized for many years. The idea is not new, as the surgical treatment of mitral stenosis was first suggested by Brunton[3] in 1902. In 1912, Tuffier[22] attempted actual dilatation of a stenosed aortic valve. In 1929, Cutler and Beck[4] summarized their personal experiences in the surgical treatment of 8 cases of mitral stenosis, the mortality for the group being 83 per cent. Since that time much progress has been made in the field of thoracic surgery. These advances, combined with recent developments in chemotherapy and the sound present-day concept of the prevention and treatment of shock minimize many of the former hazards, and should permit reapplication of certain methods with significant reduction of mortality.

Before entering into any discussion of a new surgical procedure or a new surgical approach to an old procedure, one must justify somewhat any increased mortality in the beginning. It is to be expected that as one operates in or around the heart, there will be a mortality. As a matter of fact Elliot Cutler[5] stated that though the majority of his patients died following operation, it was his feeling that the experiences gained would be of great benefit in future reduction of mortality. It may be recalled that the mortality figures in early operations on the stomach now considered relatively simple, as collected by Dr. W. W. Keen[12] for his Cartwright lectures, were quite high. Following the first twenty-eight gastrostomies collected in 1875, all the patients died, and in a series of thirty-five gastroenterostomies in 1885, the operative mortality was 65.7 per cent. Moreover, it took years for these figures to improve. In 1884, the mortality for gastrostomy was still 81.6 per cent.

It is not our intention at this time to present an extensive collected series of personal cases in which operation was performed for mitral stenosis. Indeed, it is our intention as a combined team of surgeons and internists to present some of the material that has been accumulating in the literature. It is our main intention to present some of the indications for operation, the methods used and some of the results.

Without question, there is no necessity of stating that the clinical evaluation of any patient by an experienced cardiologist is a must. In the past years, medical management of mitral heart disease has become a clinical laboratory picture, and I am sure all of you know the methods that are used currently. There are certain basic questions that must be answered before operation is indicated:

1. Does the patient have evidence of active heart infection? The report of Hench and his coworkers on compound E may indicate that perhaps in active infections the treatment of choice is compound E.

2. Is the deformity of such a nature that the patient can survive a normal span of life with moderate activity? Perhaps catheterization studies of the heart, and lung biopsies may indicate the value of an operative procedure. In co-operation with Dr. John LaBree at the University we have been attempting to correlate intracardiac pressure studies with lung biopsies. Will a surgical procedure which permits more blood to reach the left ventricle, be of benefit to patients in whom arteriosclerosis of the lungs is already present, is a question that still remains unanswered. Our studies are still too few to warrant any definite conclusions on this point.

3. When shall a patient be subjected to operation, if at all? Shall we wait until the patient is a poor operative risk, when he is in failure, or when severe hemoptysis and dyspnea are present?

4. Is mitral regurgitation worse than a mitral stenosis? Is it a gradual regurgitation that is important, or are we to believe that regurgitation is an unimportant factor completely? Is merely the relief of pressure in the left auricle the important thing, so that an interatrial septal defect would suffice?

All these questions still remain to be answered. Were we to have a tool by which mitral stenosis

---

From the Departments of Surgery and Internal Medicine The University of Minnesota and The Ancker Hospital

Read in symposium on Diseases of the Chest, sponsored by the Minnesota Chapter of the American College of Chest Physicians at the annual meeting of the Minnesota State Medical Association, Duluth, Minnesota, June 12, 1950.

could be produced consistently in an experimental animal, we are sure that most of the questions could be answered on a physiologic basis. All the procedures that will be described in the future paragraphs would then be subjected to critical evaluation. In the meantime, until a method is obtained, human experience will be our sole method of evaluation.

Surgical Considerations

Mitral Valve

The methods that we have been using in the approach of the problems of mitral stenosis seem to take one of the following three courses:

1. Methods of direct surgical attack upon the stenotic valve.
2. Methods of relieving the associated pulmonary hypertension.
3. Methods of by-passing the stenotic mitral valve.

Methods of Direct Surgical Attack Upon the Stenotic Valve

1. *Simple incision of a valve cusp.*—Cutler, Levine and Beck[4] first attempted this procedure in 1924. Their results were not encouraging. However, it must be stated that we have since made some advances in pre- and postoperative care and, perhaps, if nothing else, these authors have given us some valuable experience that is being used today. Anatomically, the stenosed mitral valve can be reached by a suitable instrument by way of either the left ventricle or left auricle. It is not yet entirely clear as to which is the better approach.

2. *Excision of a portion of the mitral ring.*—Cutler, Levine and Beck[5] also reported some cases in which a piece of the fused valves was removed, since it was felt that the only hope in mitral stenosis was to replace it by a regurgitant type of lesion. Results seem to indicate that although there has been some objection to this procedure, there are indications for it. Smithy,[18] this year, reported seven cases subjected to eight operations with two deaths, a mortality of 28.6 per cent. He has approached the valve and resected a portion by means of the ventricle and the auricle. His preference at the time the paper was published was by the transventricular method. It is interesting to remark that one of the successful results is a technician now working in a Saint Paul Hospital. In a recent conversation, she stated that she would be willing to convince anybody of its value to her. Time will provide the answer as to how well these patients will carry on with their increased, though limited, regurgitation. It must be remembered that Powers,[15] in an attempt to produce a mitral stenosis in dogs and then resect the stenosed valves, stated that in all probability, a sudden regurgitation is very harmful. He suggested that a much better approach to the problem would be had if a gradual increase in the amount of reflux of blood into the left auricle were obtained.

3. *Digital dilatation of the stenotic orifice.*—Souttar[20] in 1925 first performed this procedure with success in one case. Recently Bailey[6] and his co-workers have performed three such dilatations with one success. Death within three days in one of the cases was due to clotting at the torn commissures.

4. *Valvuloplasty.*—Harken[9] has coined this term for a method which involves the resection of portions of the valve ring at the commissures. It is his feeling and that of many others, that the antero-lateral and the postero-medial commissures should be resected. A selective type of valvular resection is thus done, and regurgitation of blood from the aorta into the ventricle is thus prevented.

5. *Commissurotomy.*—Bailey[6] and his co-workers have recently suggested that, instead of resection of a piece of the fused valves, a slit into the antero-lateral commissure, and at times into the postero-medial commissure, be done. This is done under direct digital control, a procedure which he has called commissurotomy. Ideally, surgical intervention should restore perfect valvular action; then the correction of obstruction in the light of the associated degree of insufficiency that is immediately produced would not come under consideration. He has recently reported thirty patients with six deaths. In twenty-one, the results have been satisfactory to date, both subjectively and objectively as measured by cardiac catheterization studies.

In summary, therefore, of all the procedures used in direct attack on the mitral valve it would seem that either resection or cutting of the commissures is a valuable procedure. If surgery is considered, either one of these two methods should be contemplated.

Methods of Relieving the Associated Pulmonary Hypertension

The interesting observation first reported by Lutembacher, that patients with mitral stenosis who have a co-existing patent interatrial septal defect, do not usually suffer from paroxysms or pulmonary edema, has led to the suggestion that such a defect might be created artificially in cases of mitral stenosis. Harken has created a defect in humans by means of a specially devised valvulotome. Blalock[2] has attempted this procedure, and used it in cases of transposition of the great vessels. One of us (I.D.B.) experimentally used the approach of anastomosing the auricular appendages, either directly or by means of a vein graft.[17] By this method the interatrial defect, which is in effect produced, can be made under direct vision and can be broken down immediately, should the condition of the patient warrant it.

Sweet[19] has used still another approach. He has anastomosed the superior segment branch of the inferior pulmonary vein to the azygos vein, thus creating a communication between the systemic and pulmonary circulations. Whereas the pulmonic circulation is a closed circuit, the systemic venous return is not; thus the pressure within the left auricle can be distributed over a greater area.

Methods of By-Passing the Stenotic Mitral Valve

In 1913, Jeger[11] thought that a valved vein might be grafted to serve as an anastomosis between the pulmonary vein and the left ventricle and thus adequately side-tracking the stenotic mitral valve. Recently Gross's efforts at using grafts of vessels may in the future be an answer to this problem.[8] Rappaport[16] has recently also implanted the tip of the auricular appendage into the ventricle. By this method the stenotic valve will be by-passed.

In summary, it might be said that methods of by-passing the stenotic valve are still very much in the experimental stage and should be discarded as a procedure in humans.

Indications and Selection of Patients

Indications that have been put into the literature are at this time more verbal than salted with experience. We are not saying this in a critical way, but rather to suggest that perhaps more operative procedures should be done in an effort to obtain the true criteria for operation. Harken[9] suggests a preliminary classification of patients into three groups:

Group A—This group includes patients with a low resting cardiac output which is unchanged or even decreased on exercise and with an elevated pulmonary-artery pressure. Signs of right ventricular failure may appear in addition to the pulmonary symptoms. For such patients, the operation of "valvuloplasty" may be helpful since the available evidence indicates that mitral obstruction is of major importance in this clinical condition.

Group B—In this group are patients whose resting cardiac output is within normal limits and usually increases with exercise. In spite of the adequate cardiac output, they often have as severe pulmonary symptoms as those in Group A, and the pulmonary-artery pressure is also elevated. The pathophysiologic mechanism in these cases may be a predominance of mitral regurgitation over the element of stenosis, or it may be that a high left auricular pressure maintains flow through narrowed mitral orifices to an adequate level. Secondary organic pulmonary vascular changes may also occur as an important element in producing the pulmonary symptoms. These patients may be benefited by the production of an artificial interatrial septal defect, which will decompress the left auricle and the pulmonary venous hypertension, especially at high peaks during periods of strain. This operation is probably not suitable for patients who have had right ventricular failure because of the added burden produced in the right ventricle by the recirculation of blood through this chamber and the pulmonary circuit. Such an operation may be contraindicated for patients in Group A, in whom too great a proportion of blood may be diverted through the shunt, and with decreased left pressure, blood flow through the stenotic mitral orifice would be reduced still further to a level incompatible with life.

Group C—This category includes patients whose incapacitating symptoms, particularly attacks of pulmonary edema, are associated with rapid heart action that cannot be controlled by medical measures. The cardiac output may be normal or low, and the pulmonary-artery pressure elevated. The patients are not deemed suitable candidates for either of the operations mentioned above because of the extent and severity of their disease. The occasional patient with mitral stenosis who has attacks of severe chest pain, especially "hypercyanotic angina," may also fall into this group. For these patients, a palliative procedure may be the removal of the cardiac sympathetic accelerator and afferent nerves.

Glover and Bailey[6] classify the indications as follows:

1. Most favorable group:
   - (a) Excessive fatigability.
     Increasing exertional dyspnea.
   - (b) No rheumatic activity.
     Normal sinus rhythm.
     Lesion predominantly stenosis.
     Evidence of significantly increased pulmonary hypertension.
2. Less favorable group: The above plus
   - (a) Recurrent bouts of hemoptysis.
   - (b) Arterial embolic phenomena.
   - (c) Auricular fibrillation without failure.

Hemoptysis in more than amounts necessary to stain the sputum is of grave import. Wolf and Levine[23] point out that in their series of cases the average duration of life following the onset of severe hemoptysis is 35.5 months. Levine[14] stated that the average duration of life following the initial attack of congestive failure is 4.6 years. The development of auricular fibrillation is usually permanent and irreversible. In this state thrombus formation not infrequently occurs along the endocardium of the dilated and relatively immobile auricular walls. Some 75 per cent of these occur within the lumen of the auricular appendage (left), a common site for the origin of arterial embolization.

Bailey and his co-workers contraindications would be: (1) active rheumatic infection; (2) presence of superimposed subacute bacterial endocarditis; (3) cardiac failure uncontrollable by medical means; (4) presence of marked associated mitral regurgitation or other valve (aortic) deformities.

Smithy[18] states that the ideal candidate for operation is a patient in the younger range of years having a high grade of mitral stenosis, without evidence of more than minimal involvement of the other valves, and with severe disability from mechanical obstruction but little or no evidence of cardiomegaly, hepatomegaly, venous distention, and chronic fluid retention. Disability in cases of this nature is characterized by a definite group of complaints common to each: chronic weakness and fatigue, dyspnea on mild exertion, orthopnea with acute nocturnal exacerbations, persistent, exhausting cough with or without hemoptysis, palpitation, and periodic bouts of acute pulmonary edema. In the absence of much cardiac enlargement, venous engorgement, hepatomegaly, and peripheral edema, he considers such patients to be suffering almost entirely from mechanical obstruction to the flow of blood through the heart.

It is apparent from this discussion of the indications and contraindications that the internists and surgeons should get together soon and a preliminary effort at determining the indications for surgery, which later may be modified, should be made as the surgical patients are evaluated postoperatively.

Auricular Ligation for Recurrent Embolization

One of the most common causes of peripheral arterial emboli is rheumatic mitral stenosis. This disease occasions a slowing of blood within the left atrium and left auricular appendage. This stasis of blood, coupled with auricular fibrillation, leads to frequent thrombus formation in the left atrium. These thrombi are the most common antecedents of peripheral emboli in rheumatic heart disease. Our associates, Drs. Chester Thiem, Ben Sommers, and John Noble[21] have recently studied a series of cases for location of emboli within the heart of rheumatic mitral disease. Their figures indicate that the most common source of thrombi is in both auricular appendages. Previous to this study, we had ligated three left appendages in patients with recurrent embolization and mitral disease.[1] It is our feeling that this procedure may prove to be a very useful one in the prevention of future embolization. Our indications at present for doing this procedure are as follows:

1. The patient should be fifty-five years of age or younger.
2. There should be no evidence of severe coronary disease by clinical study and electrocardiogram.
3. The patient should not be in congestive heart failure at the time of operation.
4. The patient should have had evidence of embolic phenomena.
5. There should be no evidence of subacute bacterial endocarditis.

Perhaps the anticoagulants may control the formation of future thrombi, but certainly they do not dissolve any thrombi that are already present in the auricular appendage. As a matter of fact, we would like to suggest that both auricular appendages be ligated.

Aortic Stenosis

An additional word at this time on relief of the aortic stenosis associated with mitral disease. Attempts have been made in the past to dilate the aortic ring when stenosed. Recently it has been reported in the American Surgical Association by Glover[7] and his co-worker that a section of the aortic ring has been accomplished by means of a knife placed down through the carotid artery in the neck and impinging upon the aortic valve. At the present time it might be stated that we are not clear as to the indications and contraindications for such an operation. However, it is our belief that operations of this type should and will be done in the immediate future as soon as the indications are clear.

Summary

In summary, therefore, it is our belief that operative procedure for mitral stenosis should be carried out. A more definite set of indications and contraindications should be established. Until the advent of the experimental production of mitral stenosis is with us, human material should be used and the results compiled and information obtained for future reference.

Addendum

Since this paper was submitted for publication, two patients with mitral stenosis have been operated upon successfully. In both instances the mitral orifice was enlarged by way of the left auricle.

COURSE IN PROBLEMS OF HUMAN INFERTILITY

Problems of human infertility will be discussed by gynecology specialists at the University of Minnesota's Center for Continuation Study Thursday through Saturday, September 28-30. The three-day course is open to all physicians in the state.

Fields to be discussed at the continuation course will cover such topics as the physiology of ovulation, various endocrine studies, the psychosomatic effects of sterility and artificial insemination.

Among the visiting faculty members who will direct some of the sessions will be Dr. Isador C. Rubin, clinical professor of gynecology, New York university college of medicine, New York City, and Dr. Fred A. Simmons, research assistant in gynecology, Harvard university medical school, and assistant in surgery, Tufts university, Boston.

Dr. Warren O. Nelson, professor of medicine, anatomy and histology, University of Iowa college of medicine, Iowa City, is another of the out-of-state specialists who will head discussion groups.

Present from the staff of the Mayo Foundation at Rochester to give one of the lectures, will be Dr. Lawrence M. Randall, professor of obstetrics and gynecology.

Also leading parts of the meeting will be Dr. John L. McKelvey, professor and head of obstetrics and gynecology at the University.

THE SIGNIFICANCE OF THE ISOLATED PULMONARY NODULE

DAVID V. SHARP, M.D., and THOMAS J. KINSELLA, M.D.
Minneapolis, Minnesota

THE INCREASING USE of chest roentgenograms in community surveys and routine physical examinations has confronted physicians with a variety of unsuspected chest conditions including the isolated pulmonary nodule. This condition, variously designated as the "pulmonary coin lesion," the peripheral nodule, and commonly dismissed as a "tuberculoma," presents diagnostic and therapeutic implications far out of proportion to the seemingly insignificant nodule itself.

We have studied, over a period of the past four years, a total of ninety-six such nodules in patients from twelve to eighty-five years of age. The sexes were about equally divided and all were of the white race except one Indian girl twelve years of age.

These nodules differ widely in appearance. They have been found in all segments of the lung with their location of no special diagnostic value. Their size varies from 1 to 4 centimeters in diameter, thereby excluding the large bronchiogenic carcinomas and the smaller calcified areas (Gohn tubercles). They may be round or ovoid in contour with edges smooth, fuzzy or irregular. Their density varies from very soft infiltrates to extremely dense nodules with or without calcium deposits. The presence of calcium does not establish the benign or malignant nature of the process. The degree of calcification discernible on x-ray films, as Bloch[1] has shown, is indeed arbitrary and is largely dependent upon special x-ray techniques for its demonstration. The growth of a nodule is not necessarily a sign of cancer for it has been noted in fibroma, hamartoma, adenoma and the granulomas, while lack of growth may occasionally be noted in carcinoma over many months. All nodules observed in this series were entirely asymptomatic with two exceptions (bleeding from pulmonary cysts).

When confronted with a patient whose x-ray films reveal an isolated pulmonary nodule, careful studies should be instituted at once to attempt to determine the nature of the lesion. A careful history and complete physical examination should be supplemented by special diagnostic procedures as indicated. An exhaustive search must be made for primary tumors elsewhere and for underlying disease which might produce a local lung lesion. Laboratory studies of blood, urine, sputum, gastric washings, bone marrow, et cetera, may at times give a clue to the etiology of the nodule. Results to date in attempting to establish a diagnosis in an obscure pulmonary infiltration have suggested the desirability of skin testing particularly for tuberculosis, histoplasmosis, blastomycosis, coccidiomycosis and ecchinococcous disease.[7] Originally some, at least, of these infections were considered of local interest only, but more recently the migration of large numbers of people and modern air travel have rapidly dispelled our ideas regarding a so-called local habitat of certain yeast and fungus infections. Our experience from the studies in this series would seem to indicate, however, that skin test reactions possess suggestive rather than absolute diagnostic value in the case of isolated pulmonary nodules.

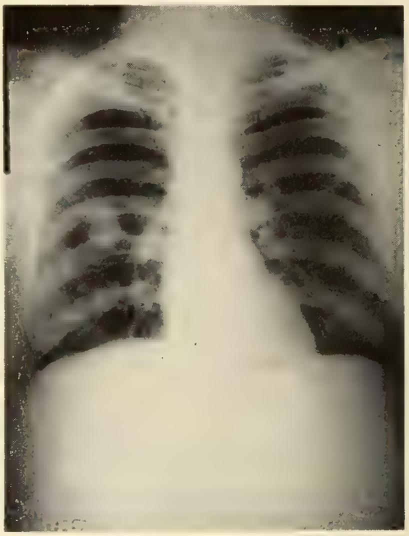

Fig. 1. An Isolated Pulmonary Nodule.

The relative frequency of tuberculosis and its tendency to involve the lung and to produce nodular areas of disease must place it high on the list of suspected causes of such nodules. Sputum, if any, must be carefully studied for mycobacterium tuberculosis. In its absence, bronchial secretions or washings obtained bronchoscopically or gastric washings may be studied cul-

turally or by guinea pig inoculation in an attempt to recover the organisms. However, the relatively high incidence of malignancy in this series (27.3 per cent) and the usual rapid growth of bronchial malignancy makes one seriously doubt the wisdom of delaying definitive action six or eight weeks for such laboratory reports. As these nodules, even if tuberculous, are frequently closed lesions, failure to recover organisms from secretions does not rule out tuberculosis.[3] The old idea that all granulomas and calcifications in the lung were the result of tuberculosis has definitely been disproven.[5,7] Our efforts to demonstrate pathologic yeasts and fungi from similar material have been quite disappointing. The presence of malignant cells in bronchial secretions is, of course, diagnostic, but small peripheral primary carcinomas and metastatic tumors do not throw off recognizable cells as regularly as carcinoma in the larger bronchi and, hence, positive cell studies in patients with isolated pulmonary nodules are but rarely found. Negative reports, however, do not in any way rule out the presence of a malignant tumor.

X-ray studies are valuable not only in discovering the nodule originally, but also in localizing its position and may, through special techniques or planigraphy, demonstrate calcification, fluid level, cavitation or other suggestive diagnostic information. Cavitation with or without fluid level may suggest a tuberculous abscess but may also be seen with other granulomas, in pulmonary cysts or even in malignant lesions. Perhaps the most valuable x-ray study may lie in a comparison of the recent with older films if available. Evidence of growth of the lesion is certainly an indication for its prompt removal. Conversely, lack of growth over a period of even a year does not prove the nodule to be benign. Certainly the common practice of recommending another film in three to six months has nothing medically to recommend it and could easily in the presence of malignancy seal the patient's doom.

While in the early portion of this series, we made extensive studies of all types listed in an attempt to gain information which might help us to arrive at a correct clinical diagnosis, we have, as a result of the experience gained by these studies, reached the conclusion that the only reliable and accurate diagnostic procedure is exploratory thoracotomy with excision and prompt pathological examination of the mass. When, with the lung exposed and in the surgeon's hand, it is often impossible to accurately state the nature of the nodule, how can indirect studies be expected to furnish the answer?

TABLE I. ISOLATED PULMONARY NODULES.

Proven			55
Malignant	15 (27%)		
Bronchogenic Carcinoma		11	
Lymphosarcoma		1	
Metastatic (Breast, Colon, Testicle)		3	
Inflammatory	22 (40%)		
Granuloma			
Ecchinococcus		1	
Tuberculosis			
(Proven)		6	
(Suspected)		5	
Unproven		10	
Benign Tumors	18 (33%)		
Hamartoma		5	
Chondroma		1	
Adenoma		2	
Fibroma		2	
Bronchial Cyst		8	
Undiagnosed Nodules			41
TOTAL			96

From this series of ninety-six nodules listed above, fifty-five have been definitely proven by surgical operation (forty-nine) or by medical means (six). We have accepted as final medical proof the positive bronchoscopic biopsy of malignancy or the progression of such a lesion to fatal termination, the recovery of tubercle bacilli or the demonstration of a proven primary tumor elsewhere. Fifteen (27.3 per cent) of the fifty-five proven nodules were malignant. Eleven were due to primary bronchiogenic carcinoma, one to a primary lymphosarcoma in the periphery of the lung and three to solitary metastatic nodules from carcinoma of the breast, colon and testicle. Eighteen (32.7 per cent) were found to be benign tumors of the types listed in the table above. The number of pulmonary cysts and hamartomas in this group is somewhat higher than in the average reported series. Twenty-two (40 per cent) of the nodules proved to be inflammatory lesions or granulomas. Formerly erroneously called tuberculomas under the mistaken idea that all were tuberculous in nature, we now know that a variety of infectious agents may produce them. Granulomas may vary widely in gross and microscopic appearance from an abscess, a blocked or inspissated cavity full of soft caseous material, through all stages of attempted healing to the very mature granuloma showing the concentric rings resembling the growth rings of a tree. The myth of the harmless "tuberculoma" which need not be disturbed is easily dispelled by viewing a few of these excised granulomas which are caseous areas either primary or secondary or blocked or inspissated cavities whose contents, often teeming with bacilli, only await bronchial communication to spread infection widely throughout the lung.

The microscopic picture of most granulomas of varying etiology is strikingly similar and the only positive proof of the tuberculous or other specific etiology of such a lesion is the demonstration of the specific organism from it. The number of proven tuberculous granulomas (six of twenty-two) is rather small for this reason. We have listed five others as suggestive of tuberculosis because of the clinical findings and microscopic picture in and about the nodule and have wondered if the preoperative forty-eight-hour administration of streptomycin may have been a factor in negative cultures reported in this group. To date, our attempts to isolate other organisms from a group of these nodules through the co-operation of the mycologists at the University of Minnesota and the State Board of Health have been disappointing, hence, the ten nodules of undetermined etiology. Perhaps studies with other techniques and media may reveal more in future specimens. The fact that some of these nodules unquestionably represent completely mature and burned out lesions must also be considered. The forty-one undiagnosed nodules listed represent a group of patients who have either not completed their work up or have refused or postponed exploratory thoracotomy as recommended to the physician.

There has been no surgical mortality or complication in this series of surgically treated patients. The usual procedure has been, at open thoracotomy, to excise the local nodule by means of a wedge resection and suturing the lung behind clamps while the pathologist is making his examination of the excised nodule. This technique has been preferred to local enucleation which works very nicely with hamartoma and a few of the lesions but which can lead to gross contamination if abscess or active tuberculosis is encountered. The procedure has been extended to segmental resection, to lobectomy or even to pneumonectomy as local conditions and the pathologist's findings warrant.

This experience and the published reports of others have convinced us that an accurate preoperative diagnosis of the nature of an isolated pulmonary nodule is impossible in the vast majority of instances. Exploratory thoracotomy and immediate pathological examination provide the only accurate means of determining the exact nature of the lesion. The low calculated risk of such a procedure and the relatively high incidence of malignancy (27.3 per cent) in this series (40 per cent in other reported articles)[2,4,8] makes it the only safe and logical method of treating the isolated pulmonary nodule.

ARMY AUTHORIZES APPOINTMENT OF WOMEN DOCTORS AS RESERVE CORPS OFFICERS

Appointment and concurrent assignment to active duty as Reserve Officers of women physicians, dentists, and allied specialists, has been authorized, it was announced August 30 by the Department of the Army.

They will be brought on duty under regulations currently providing for the commissioning of male officers in these Corps. Some women did serve in the Army as physicians and technicians during World War II, but their commissions have expired and legislation permitting their commissioning expired in 1947.

As Reserve officers on active duty, these women will be given opportunities for clinical practice and advancement which are now available to male officers in comparable grades, Major General R. W. Bliss, Surgeon General of the Army, pointed out. Appointments will be in grades from first lieutenant to colonel, depending upon age, experience, and professional qualifications. The pay, allowances, dependency and retirement benefits which accrue to male officers will apply to the women medical reservists. Women physicians and dentists will also draw the $100 a month professional pay allowed above the base pay of their commissioned rank. They will be eligible for service in every type of military medical facility, with the exception of forward medical installations in combat zones.

General Bliss said his office had received numerous letters during the past year from women physicians desiring military service.

CLINICAL DETECTION OF PULMONARY EMPHYSEMA FROM RESPIRATORY TRACINGS

PHILIP H. SOUCHERAY, M.D.
Minneapolis, Minnesota

IN THIS DISCUSSION, I should like to attempt to illustrate the irrationality of attempting to estimate pulmonary functional reserve or determine the cause of functional disability from any single measurement of respiratory activity. The respiratory system is more than a mechanism for moving air in and out of the body: air must be moved in order to ventilate terminal pulmonary alveoli, but the lung itself exists mainly to support a vascular bridge between the right ventricle and left auricle.[4] This vascular bridge, made up of nets of capillaries in the alveolar walls, must accommodate the greatly varying minute output of the heart in a manner quite different from that in which an increased flow is handled by the general circulation. As the flow across the pulmonary bridge increases the pressure, the rate of flow in the lesser vessels normally does not rise, but rather the blood diffuses out into previously unopened capillary beds where respiratory gas exchange may then take place in the usual leisurely manner.

Figure 1 is borrowed from an excellent article on determination of pulmonary insufficiency[5] where it appeared recently, and illustrates the processes occurring within a normal lung. The air flow through the upper U-tube, the ventilatory phase of the respiratory process, might be measured with a clinical spirometer, and ordinarily amounts to between 4.5 and 6 liters per minute. The total volume of air that could be moved through the tube in one breath represents the vital capacity while the actual volume of the circuit constitutes the residual air or dead space within the lung. The dotted line between the opposed U-tubes represents the capillary-alveolar interface, and respiratory gas exchange takes place across the cross-hatched area. The area of the circuit marked "dead space" represents the fact that not all of the air ventilated reaches the capillary-alveolar interface. This "dead space" or residual air volume has been studied extensively,[1] and it has been found to be slightly less than 28 per cent of the total lung volume in a healthy man. Any increase in the residual air practically always indicates the presence of pulmonary emphysema.

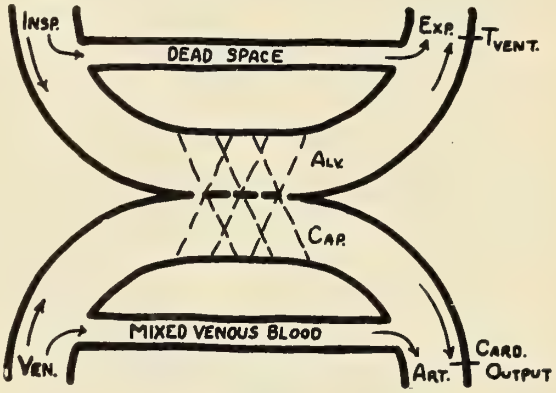

Fig. 1. Normal ventilation. Normal circulation.

The inverted U-tube represents the pulmonary circulation. The dynamics of this segment of the circulatory system have been investigated only since the advent of cardiac catheterization through a peripheral vein. By this means the pressures in the right ventricle and pulmonary artery have been measured, and from the rate of oxygen utilization the rate and volume of blood flow through the lung have been determined. It is important to remember that normally the pressure never rises in this system despite increases in minute volume of flow. Any increase in flow is accommodated by the opening of non-perfused capillary beds. If the necessary volume of new beds is not available because of some obliterative disease, then the pressure within the system must rise, and flow is speeded through the capillaries, or shunted around the beds completely.

Figure 2 represents the conditions which prevail when the airway is obstructed but the pulmonary circulation is left intact. The diagram might represent the picture of acute bronchial asthma, suffocation, spontaneous pneumothorax, or some types of pulmonary fibrosis. The causes of acute obstruction of the respiratory tract are

usually apparent, but before one could be sure that a chronic pulmonary disease was due solely to ventilatory dysfunction the dynamics of the pulmonary circulation would have to be investigated by cardiac catheterization.

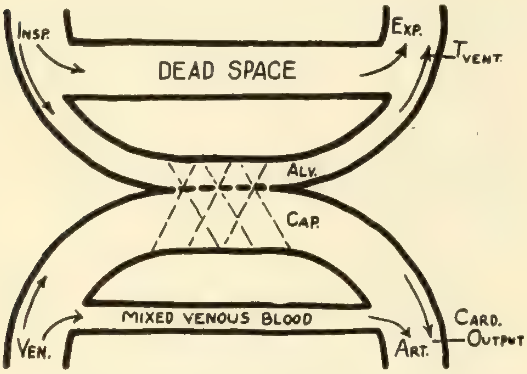

Fig. 2. Diminished ventilation. Normal circulation.

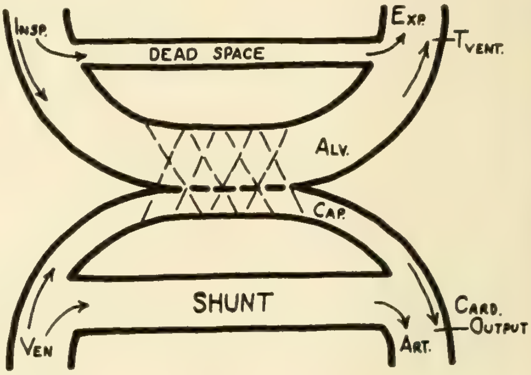

Fig. 3. Normal ventilation. Diminished circulation.

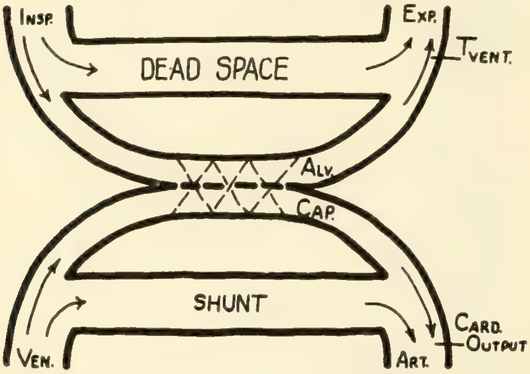

Fig. 4. Diminished ventilation. Diminished circulation.

Figure 3 represents the conditions which might prevail in cases of pulmonary hypertension due to pulmonary arteriosclerosis, either primary or secondary to some other disease such as mitral stenosis or some types of pulmonary fibrosis.[2] These diseases are certainly diseases of the pulmonary system and may present the picture of undue fatigue or dyspnea on exertion, cough, or hemoptysis. But without actual measurements of the dynamics of the pulmonary circulation, the real disease may lie undisclosed and, perhaps, unsuspected. Measurements of the ventilatory function alone would probably be normal and thus might even serve to turn one's attention away from the pulmonary system as the seat of disease.

Finally, Figure 4 illustrates a combination of circumstances in which there is both diminished ventilation of the alveoli and impaired perfusion of the capillary beds. This is the functional picture of pulmonary emphysema whether it be the hypertrophic bullous type, senile degenerative type, or the compensatory type seen surrounding a contracted scar of tuberculous inflammation or in portions of a lung distorted by the retraction of fibrous pleuritis. All chronic pulmonary emphysema is characterized by distention or distortion of alveolar spaces, loss of interstitial elastic fibers, and hypertrophy of the muscular layers of the arterioles with obliteration of associated capillary beds. To be able to detect or even suspect the presence of this type of combined ventilatory and circulatory disease would be a distinct advantage to the clinician because people harboring this type of pathology have lost a great deal of their ability to adapt either to an increased demand for oxygen-carbon dioxide exchange, or to an increased rate of blood flow through the pulmonary vascular bed. They are in a poor position to withstand any operative procedure within the thorax, they are more than usually susceptible to the pulmonary infections that so frequently follow general surgical procedures under anesthesia, and they suffer from a real disability which is often differentiated from malingering only with great difficulty.

In a recent study of pulmonary disability in cases of anthrasilicosis[6] through a comprehensive battery of both clinical and physiological tests two important conclusions were brought forth: first, pulmonary emphysema is the pathological process associated with most disabling pulmonary disease and, second, about one-half of the cases of advanced pulmonary emphysema may evade a competent examiner and be found only after extensive examinations of pulmonary function far beyond the scope of any clinical laboratory. It

TABLE I. SEPARATION OF CASES OF EMPHYSEMA

By Means of Measurement of Lung Volume and from Consideration of the Character of the Respiratory Tracing

Classification	Vital Capacity	Alveolar Nitrogen Vol. %	Residual Air / Total Lung Volume	Distribution of Patients by Laboratory Measurement	Distribution Within Each Group from Consideration of Tracings Only
Group 1 Normal	Over 3500 c.c.	Less than 2.5	Less than 28%	9	All of the 18 patients in Groups 1 and 2 fell into the "grossly normal" classification.
Group 2 Slight emphysema	2500-3500	2.5-3	28-35	9	
Group 3 Moderate emphysema	1800-2500	3-5	35-45	2	18 of the 19 patients who were in Groups 3 and 4 fell into the "grossly abnormal" classification as did one patient from Group 2.
Group 4 Severe emphysema	Less than 1800 c.c.	Over 5	Over 45%	17	

also seemed apparent that symptoms of pulmonary insufficiency were dependent not so much on the silicosis or fibrosis as on the degree of pulmonary emphysema present.

Some years ago Christie described the breathing patterns of some organic as well as functional diseases. Figure 5 is a normal respiratory tracing. Note that the rate and depth of the breathing action are quite regular, and that the resting or mid-position of the chest is constant. The complemental air is over half the vital capacity and as it is expired, notice that the expiration line is not curved. Notice too that the chest returns to the mid-position after either deep inspiration or deep expiration. Figure 6 is a respiratory tracing illustrating moderately severe emphysema. The respiratory rate is rapid but not always regular, and there is some variation in depth of breathing. This case of emphysema was probably of moderate severity because the complemental air is little diminished. Two things, however, do indicate loss of pulmonary elasticity: (1) the curved expiratory lines as rate of expiration slows toward the end when more and more accessory muscles are called into play, and (2) the failure to return to a constant mid-position after either a deep inspiration or forced expiration.

An attempt has been made here to evaluate Christie's indications of emphysema in respiratory tracings by recording the impression gained from considering the vital capacity as well as other characteristics in spirometric tracings made by thirty-seven patients, most of whom were suffering from some cardiac or pulmonary disease. These impressions were then compared with actual measurements of the ratio of residual air to total lung volume made on the same patients. In many there was also available the measurement of the nitrogen concentration in the alveolar air after the patient had been breathing pure oxygen. This type of measurement was developed by Cournand and associates as an indication of thoroughness of ventilation of all the alveoli. In a normal well-ventilated lung less than 2.5 volumes per cent of nitrogen remain in the alveolar air after the subject has breathed pure oxygen for seven minutes. Any increase in the residual nitrogen usually signifies poor ventilation, most often due to the distended alveoli of pulmonary emphysema.

The thirty-seven cases were divided into a group of normals and three groups representing emphysema of varying degrees of severity. Division on the basis of laboratory examination alone included as normals any patients who had a residual air to total lung volume ratio of less than 28 per cent and an index of alveolar ventilation of 2.5 volumes per cent or less of nitrogen in the alveolar air. On the basis of inspection of the respiratory tracings, the normal group had a vital capacity in excess of 3500 c.c., showed rapid expiratory rate, and readily returned to the resting position after either a forced inspiration or forced expiration.

From Table I it is apparent that the two methods do not give parallel results, but notice that there is complete separation of normals and borderline cases from cases of severe emphysema. The clinical impression failed to detect only one case of slight emphysema but called five normal persons slightly abnormal.

Thus, with an adjunct system of examination only one abnormal person was missed. If examination of the respiratory tracings had been a part of the general physical examination which

(Continued on Page 896)

RESPIRATORY ALLERGIES IN CHILDREN

LLOYD S. NELSON, M.D., and ALBERT V. STOESSER, M.D
Minneapolis, Minnesota

RESPIRATORY allergies are present in the young child more frequently than are commonly diagnosed. A persistent nasal discharge in an infant is often casually attributed to irritation of the nasal mucosa by regurgitated vomitus, or to lint from bed clothes and fuzzy garments, or it may be dismissed as a common cold. The underlying possibility of allergy is not even considered until numerous repetitions of these symptoms have occurred or until true asthma develops.

In a study of 164 cases of asthma, Buffin[2] showed that 20 to 30 per cent of these children exhibited their first allergic symptoms before two years of life. The onset of bronchial asthma in the young child may be gradual or sudden. In those cases of gradual onset, frequent episodes of croup occur. Later, bronchitis with a chronic persistent cough develops. This cough is provoked by sticky secretions which initiate paroxysms of coughing that simulate pertussis. Wheezing appears next, usually in the presence of superimposed respiratory infection, and finally true asthma develops. The onset of asthma in the young child may be sudden and dramatic. The initial attack is rapid and appears immediately after the ingestion of some offending food or exposure to some irritating inhalant. In this group of cases there is usually no history of antecedent nasal symptoms. These patients frequently reveal isolated wheal formations upon skin testing. The management and treatment is simpler and more rewarding than in the gradual type of onset. Unfortunately, the number of cases of this type are in the minority. Asthma which develops early in life is likely to be more severe than that originating later.

In comparing asthma of the infant with that of the adult, some very startling differences are noted. The asthmatic infant does not manifest the same degree of dyspnea as the adult. The wheezing, with prolongation of expiration which is so common in the adult, is never seen in the same degree in the infant. These differences are probably due to the softer thoracic wall and the predominantly abdominal respirations of the infant. The young child does not exhibit the same degree of anxiety which is characteristic in the older patient. It is common to find children playing unconcerned, and yet on auscultation of the chest, there are present definite wheezes and râles.

Older children with nasal allergy present symptoms of recurrent nasal congestion, mouth breathing, watery-clear nasal discharge, and an associated hacking cough which is usually more prominent at night and disappears shortly after awakening. These children are irritable, restless, often temperamental individuals, and are erroneously labeled behavior problems.

Too many of these cases are subjected to tonsillectomies in the hope that fewer so-called "colds" will develop. Piness,[9] as early as 1925, warned that tonsillectomies, when performed for the relief of allergic symptoms, end in failure. Bullen[3] reviewed a series of 1000 children with allergic manifestations who had had tonsillectomies, and concluded that this procedure was of no help in the treatment of allergic children. Clein[4] also studied this problem and showed that in the majority of those cases in which lymphoid tissue reappeared in the pharynx following tonsillectomy there was present an underlying undiagnosed allergy.

Where sound surgical indications for tonsillectomies and adenoidectomies are present, the operation should be done, but not until the underlying allergic problem is properly diagnosed and under competent management. There is proof that if this procedure is done during the pollen season, a latent pollinosis, or asthma, may develop. A few of these children with abundant lymphoid tissue in the oral and naso-pharynx are benefited by radiation therapy.

If nasal symptoms are not controlled early in childhood serious disturbances of growth and development may occur. An obstructed nasal passage leads to mouth breathing with poor aeration of the sinuses resulting in their maldevelopment, and thus permanently affecting the facial contours. The low grade obstruction to the eustachian tube predisposes to frequent attacks of otitis and inevitable hearing loss.

The diagnosis of allergy in the infant and child

From the Department of Pediatrics, Medical School, University of Minnesota.

Presented at the ninety-seventh annual session of the Minnesota State Medical Association, Duluth, Minnesota, June 13, 1950.

is extremely important because if the symptoms are controlled early, the likelihood of major allergic disease in adulthood with the irreversible anatomical changes such as palatine and facial deformities, emphysema and bronchiectasis is decreased. Children, when correctly diagnosed, usually respond dramatically to allergic control. It is a fallacy to assume that the child will outgrow his allergies. Clein[5] followed 100 cases of allergic children over a period of 10 to 15 years and discovered that the majority of these cases revealed their first symptoms before the first year of life. What is more startling is that 98 per cent of these 100 cases developed major allergic symptoms before their tenth birthday. This means that most of the major allergic symptoms in children are preschool problems.

The differential diagnosis of allergic rhinitis is relatively easy and will be discussed later, but the differential diagnosis of asthma is considerably more complex. Glaser[7] cautions that not all wheezing can be attributed to asthma. The differential diagnosis must include congenital stridors, foreign bodies, bronchial stenosis, laryngo-tracheo-bronchitis, pertussis, and pneumonitis. The possibility of a tumor mass, tuberculosis, or even fibro-cystic disease of the pancreas should be considered. Tracheal vascular anomalies and laryngo-spasm, due to tetany, must be differentiated in the young infant. A roentgenogram of the chest, or fluoroscopy, should be requested where any doubt of the diagnosis exists.

The presence of a concomitant allergic manifestation such as eczema or urticaria makes the diagnosis simpler. In diagnosing allergy, the family background is extremely important. Numerous studies concerning the hereditary factors in allergy have appeared. In general, the antecedent family history is positive in from 50 to 75 per cent of allergic individuals. This high incidence of family allergic history is in contrast with the low antecedent family history found in normal non-allergic persons of only 7 per cent. Vaughan[12] points out that the majority of allergic individuals who have a history of allergy in both parents will show evidence of their disease before ten years of age.

The history, properly taken, is the most valuable tool in considering an allergic problem. It should include the type of environment, habits of the child, and a chronological order of the symptoms. It is important to inquire concerning any seasonal relationship to the symptoms.

The investigation of the allergic patient should include a thorough physical examination. The general state of health must be evaluated, endocrine disturbances ought to be ruled out, and the foci of infection eliminated. The routine urine, blood count, and Mantoux tests should be requested. Upon examination of the nose, the airway is found to be narrow and inadequate. The nasal mucosa is a pale blue-grey color and varied degrees of edema and discharge are present. The presence of polyps is rare in children, but is seen frequently in the young adult. The pharyngeal wall is often studded with islands of lymphoid tissue giving a cobblestone-like appearance. In some of the older children the nasal mucosa, instead of being pale gray, is a deep red color. Obstruction of the nasal airway in these patients is the presenting symptom. Incidentally, this group of children do not respond well to the antihistamine group of drugs. The nature and the amount of the nasal secretion vary considerably. In the uncomplicated patients with allergic rhinitis these secretions are thin and clear, but, if an associated infection is present, the secretions are purulent and viscid. In either case, smears of the nasal secretions should be made. In the thin secretions, numerous eosinophiles will be seen. In the purulent secretions there will be clumps of polymorphonuclear cells present in addition. Roentgenograms of the sinuses frequently show thickening of the sinus mucosae, but in most cases this is due to edema and not to infection. The emphysematous chest, with flattened diaphragm and accentuated bronchovascular markings in the asthmatic individual, needs no further comment.

Investigation by cutaneous skin tests is indicated where definite allergy has been diagnosed, but a patient should never be skin tested in the hope of diagnosing an allergic condition. The method of performing skin tests has been the subject of considerable controversy, but in children the puncture technique is the method of choice. The application must be uniform, and fresh antigens are a necessity.

The mere performance of skin testing does not constitute a diagnostic procedure. In the interpretation of these tests, the child's age, food habits, environment, and severity of symptoms must be considered. The tests are of immense value if the limitations of this procedure are appreciated. Stoesser[10] stresses the fact that there is no correlation between the intensity of the skin reaction and the allergen's clinical significance. The complete elimination of the offending allergens would be ideal. In the young infant, in whom the diet is simple, and in whom the environment can be controlled, elimination of allergens is usually more successful. This is not possible in the older child.

The successful management of allergic diseases depends upon the thoroughness of the allergic investigation, the co-operation of child and parents, and the choice of medication. The majority of the failures in treatment are due to the fact that physician and patient alike expect a cure by the simple elimination of a few isolated allergens or by a few weeks of dietary restriction. A great deal of time and effort must be expended if good results are to be expected. Frequent interviews with the parents are necessary. The importance of such allergens as household pets, animal danders, insecticides, blooming plants, orris root, and smoke must be stressed. Adequate rest is a necessity. It is necessary to restrict physical activity. Swimming is usually curtailed because of irritation by water in the nose. The possible harm from long rides in the country during the pollination season must be pointed out.

Because of these restrictions, the psychological stresses on the already chronically ill child are increased. Bakwin and Bakwin[1] have emphasized the emotional factors in asthma. The allergic child may become overprotected and consequently become extremely dependent on the mother. One must constantly stress substitution in the child's management, and the need for outlets in activities which do not jeopardize the allergic condition.

Hyposensitization yields the best results in pollinosis and in the treatment of pollen asthma. Only mediocre results are obtained with inhalants. Molds are poor antigens, and in children hyposensitization with these antigens is of doubtful value. The attempt to hyposensitize to foods is usually disappointing.

The use of nose drops in the allergic individual is justifiable only for temporary relief. In children 0.25 per cent neosynephrin, 0.5 to 1 per cent propadrine hydrochloride, 0.5 to 1 per cent clopane, and 1 per cent onethyl sulfate may be employed. The antihistamine drugs are of value in allergic rhinitis. Stoesser[11] classified these drugs according to their general effectiveness. Antistine, neohetramine, and neoantergan give fewer side reactions but are also relatively weak drugs. Thephorin, chlor-trimeton, pyrrolozote pyribenzamine and benadryl are the more powerful members of this group. Thenylene, diatrin, histadyl, tagathen, chlorathen and decapryn are intermediary in action. In some children a sedative effect is desired and for these patients drugs such as decapryn or benadryl are particularly suited. A few children need added stimulation and this can be accomplished by thephorin. Some of the antihistamines have a very decided atropine-like action and are harmful in that they tend to dry the secretions and thereby precipitate asthma.

The use of antihistamines in the treatment of bronchial asthma has been highly overrated. Feinberg[6] makes this statement, "In the last three to four years as a result of high-powered publicity, the substitution of the antihistamines for the more efficient anti-asthmatic remedies and allergic management by physicians and patients has resulted in an actual deterioration of the management of asthma." The use of the antibiotics in the acute attack of asthma is abused. This may be due to the misconception that the asthmatic attack is caused by the infection alone. If the concept of underlying allergy with superimposed infection were clearly understood, a more reasonable plan of treatment would be followed. One must remember that these drugs, particularly penicillin and aureomycin, and to a lesser degree terramycin, are capable of sensitization.

The primary disturbance in bronchial asthma is obstruction of the bronchial tree by edema, smooth muscle spasm, and retained secretions. The main objective is to clear the bronchial tree of obstruction. Expectorant cough mixtures incorporating potassium iodide, sodium or potassium citrate, ammonium chloride or ipecac are essential in good management. Numerous mixtures of these drugs in combination with sedatives and antihistamines are available. Hydration in the asthmatic patient is extremely important. The ill child tends to become dehydrated thus further concentrating the secretions and often dramatic results by simple administration of fluids are obtained. The sympathomemitic drugs such as orthoxine, racephedrine, propadrine hydrochloride, benzylphedrine, isuprel and epinephrine are needed for their bronchodilator effect. These drugs may be used alone, but usually in conjunction with a sedative and/or an antihistamine. Syrup of orthoxine works well in the young infant, while franol, amodrine, tedral or amesec can be used in the child capable of swallowing a tablet. Epinephrine is the best drug in the treatment of the acute attack. Rubin, in Mitchell-Nelson's textbook,[8] states that small doses of adrenalin injected hypodermically may be given at frequent intervals for many days without harmful effects. Doses of 2 or 3 minims give just as effective relief as larger doses and the side effects are minimal. Epinephrine in oil or in gelatin may be employed for a more lasting effect, but be careful that the child is not sensitive to the vehicle used.

The xanthine drugs are also bronchodilators and of this group aminophylline works well. It may be used orally, rectally, or intravenously. In children, this drug frequently produces nausea and vomiting.

Conclusions

1. Allergic diseases of the respiratory system are common in the young child, but because of their insidious onset they are commonly misdiagnosed.

2. The most important factors in allergic management are a thorough allergic history, a detailed examination including skin tests and a complete orientation of both the parent and the patient.

3. Allergic children are commonly subjected to needless tonsillectomies.

4. The use of the antibiotics in allergic diseases has been abused.

5. The antihistamine drugs are of some help in children with allergic rhinitis. However, their value in the treatment of asthma has been highly overrated.

6. A return to a more rational form of therapy in asthma, using expectorants, hydration and bronchodilator drugs is indicated at this time.

CLINICAL DETECTION OF PULMONARY EMPHYSEMA FROM RESPIRATORY TRACINGS

(Continued from Page 892)

included fluoroscopic examination of the chest, I feel certain that separation of persons with all degrees of emphysema from the normal group would be nearly complete. As part of a screening examination attempting to detect the presence of combined ventilatory and circulatory impairment in persons with pulmonary disease, consideration of respiratory tracings made on the ordinary clinical spirometer may be a very simple yet rewarding procedure.

CANCER OF THE LARGE BOWEL

HENRY FISKETTI, M.D.
Duluth, Minnesota

CANCER of the large bowel is reported in sufficient frequency at St. Mary's hospital, Duluth, to make it a subject of interest and to warrant a review of all cases that have been treated in the years 1938-1947 inclusively. The fact that there are approximately 16,000 cases of cancer of the large bowel in the country annually poses a tremendous surgical problem. Such factors as better medical training in the various medical schools, the education of the public by the cancer control programs, more refined methods of diagnosis, and so forth, have no doubt contributed to its greater incidence in recent years. But, notwithstanding, there are still too many cancers of the large bowel that are seen at a stage of inoperability. This is especially true of cancer of the right colon, where obstruction is not an early occurrence. The disease is insidious to the point of hopelessness in some cases. Careful attention to history and a good physical and rectal examination will lend to early diagnosis. Over 50 per cent of lesions of the rectum and sigmoid are within reach of the average index finger, and still this simple but admittedly not too esthetic clinical maneuver is too often omitted. Extirpation of the lesion is possible in most cases, and in comparison with the survival rate of cancer in other organs, cancer of the colon is one of the most favorable for cure. Early diagnosis is of the essence, the responsibility being that of the attending physician, and not entirely the roentgenologist. To be well versed in proctoscopy is to diagnose cancer of the sigmoid early, but too few are skilled in the use of the proctoscope. To pass the same blindly, without caution, and without experience or some training is often disastrous, and seldom revealing. The patient is entitled to a careful consideration of abdominal discomfort, change in bowel habits, melena, fatigability, weight loss, and so forth, and unexplained symptoms warrant further study or periodic observations. In most series, the average delay from the onset of symptoms to hospitalization is about six months, which is far too long. However, once the diagnosis is made, the responsibility for competent care is that of the good surgeon whose surgical judgment will be guided by the absence or presence of obstruction, infection, and the general condition of the patient.

Surgical judgment means not only if and when to operate but what type of procedure should be done with minimal risk to the patient. A résumé of the indicated surgical procedures thought best by some of the recent writers on the subject will be cited a few paragraphs later.

TABLE I. NUMBER OF CASES PER YEAR

Year	No.	Per Cent
1938-42	24	23.1
1942-47	84	76.9
Total	108	100

TABLE II. SEX INCIDENCE

Sex	No.	Per Cent
Male	45	41.7
Female	63	58.3
Total	108	100

Incidence

Carcinoma of the colon comprises 10 per cent of all carcinomas and approximately one half of these are in the rectum. The sigmoid is next, the cecum is third.

An attempt is made to compare the site of predilection of cancer of the large bowel with other series of the larger clinics, and we see that the St. Mary's series corresponds rather closely.

TABLE III

	1931-45	1936-44	1907-28	1937-47
Source	Hines Vets.	Lahey	Mayo	St. Mary's
No. of Cases	1,330	1,457	3,542	108
Involved Sites and Percentages:				20 cases
Cecum	7.7	6.5	6	18.5
Ascending Colon				9 cases
Hepatic Flexure				7 cases
Transverse Colon				11 cases
Splenic flexure				6 cases
Descending Colon				6 cases
	15.9	17.1	17	36.1
Sigmoid	13.0	12.4	13.55	
				54 cases
Rectosigmoid	63..5	62.8	62.8	50.

The remarkable consistency of the above figures certainly belies any belief that geography, climate, social strata, and so forth have any influence on the incidence of carcinoma of the bowel. In fact, it would seem that this constancy of predilection depends more on basic anatomical structures and on local physiology.

At this point it is apropos to review the intrinsic blood supply of the large bowel and rectum, as the success of an anastomosis depends primarily on the blood supply. A beautiful anastomosis in a bloodless segment means nothing but disaster, but a good blood supply may minimize the dangers of the not too competent juncture.

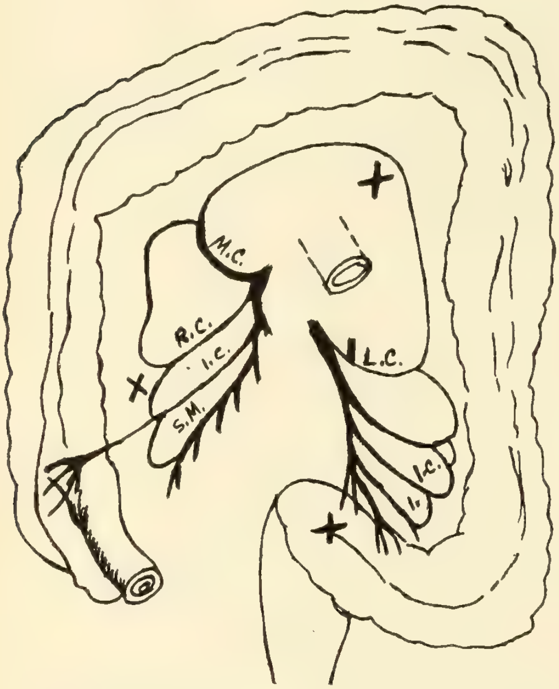

Fig. 1. X denotes weak points in marginal anastomosis.

Investigation into the blood supply of the colon has been stimulated by failures in colonic surgery, and injection of the arteries in cadavers has been the chief method of study. It is noted that the lymphatic supply is abundant and that the lymph channels follow closely the blood vessels to the origin of the mesenteric arteries. The extent of possible removal of the lymphatics is often limited because to remove them is to sacrifice vital blood vessels. In one's zeal to accomplish permanent cure, large vascular trunks may be ligated, endangering the circulation to the ileum and to longer colon lengths than anticipated.

The blood supply to the large bowel is from three major sources:

1. Superior mesenteric artery.
2. Inferior mesenteric artery.
3. Internal iliac branches:
    - a. Middle hemorrhoidal.
    - b. Inferior hemorrhoidal.
    - c. Pudendal artery.

Also, a better understanding of the colonic circulation may be had if we consider it in this light:

1. Main arteries.
2. Marginal artery, so-called the artery of Drummond and the vasa-recta.
3. The vessels within the bowel wall.

The marginal artery of Drummond joins the circulation from both mesenterics. This can be demonstrated by injecting media into either mesenteric artery and recovering it from the other. The vasa brevia are both long and short and enter the bowel on the mesenteric side naturally. The omentum with its good supply may have a part in colon surgery. Its blood comes from the gastric vessels, mainly the gastroepiploic. Its power of rapidly becoming adherent to the peritoneal surface, sealing over areas of questionable circulation and reinforcing suture lines is well known.

Although there are disadvantages in the arrangement of the blood supply to the colon, it still has some good points. We should be aware of the fact that all its arteries come from the center of a rectangle formed by the loops of the colon and radiate peripherally from the center. This means that the peritoneal reflection on the lateral aspect of both the descending and ascending colon

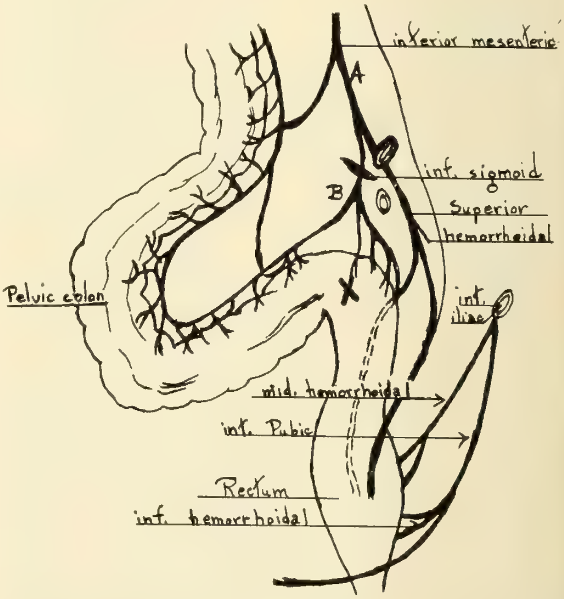

Fig. 2. Blood supply to the rectum, which is more richly supplied with blood than the other parts of the large bowel.

may be freely incised without encountering vessels and permits easy delivery of these segments of bowel from the abdomen, thus facilitating resection. The splenocolic ligament at the splenic flexure may require ligation for bleeding, but the attachment at the hepatic flexure may be severed with impunity.

Symptoms

A few points about symptoms. Usually an average from six to ten months elapses from the onset of symptoms until something medical is done. The first symptom may be sudden obstruction or perforation. Lahey states that at his clinic the time interval for all cases averages nine months with no betterment in recent years.

Unfortunately, many patients still undergo trial medical treatment too long: hemorrhoidectomies, appendectomies, and other surgical procedures before diagnostic studies are instituted. This is bad because the resectability of the tumor varies directly with the time of its existence. The following are the symptoms most frequently associated with tumors of the large bowel:

Abdominal Distress.—This is frequently more marked in the region of the descending colon, although often obstruction of the left colon will cause most distress in the dilated right bowel. Tenderness is chiefly on an inflammatory basis due, most likely, to degeneration of the tumor with secondary infection. The amount of distress depends upon the degree of obstruction and is usually aggravated by eating and relieved by a bowel movement. In about 8 per cent of the left colon lesions, acute obstruction is the first symptom. It is said that 5 per cent of the sigmoid tumors begin this way. Carcinoma of the cecum frequently is first diagnosed at appendectomy when the true pathology is usually noted by the surgeon. Further radical surgery at this time is done without the benefit of good preoperative preparation.

Change in Bowel Habits.—This is very important. A careful history may reveal alternating constipation and diarrhea. It is the contention of many that unfortunately this is not too early a sign and that it signifies considerable change in the mucosa or lumen of the bowel.

Mass in the Abdomen.—Many times this is the presenting complaint. Ten per cent of patients with carcinoma of the cecum discover a lump before the doctor. These patients are naturally thin ones, whose sigmoid and cecal areas can be easily palpated.

TABLE IV. DURATION OF SYMPTOMS

Duration	Number	Per Cent
Under 6 months	62	57.4
Over 6 months	16	14.8
Uncertain	30	27.8
Total	108	100

TABLE V. CLINICAL SYMPTOMS AND FINDINGS

	Neg.	Pos.	No. Inf.
Weight Loss	19	48	41
Anemia	22	23	63
Pain			
Upper Abdomen		11	
Lower Abdomen		35	
Both		32	
Palpable Mass	51	37	20
Occult Blood	26	31	51
Obstruction	8	66	34
Gross Hemorrhage	5	2	101
Perforation	5	3	100
+ X-Ray	37	34	37
Proctologic Exam.		28	80

Weight Loss.—Contrary to the usual belief, this is often an early sign and is nearly always present.

Blood in the Stools.—Found in about one-third of the patients with lesions in the left half, but in only 8 per cent with right colon involvement.

Other Complaints.—Anemia is characteristic of cecal involvement. The mechanism of the early anemia in cecal carcinoma is not clearly understood. Nausea, vomiting, weakness, anorexia, are other symptoms that are found and indicate some wasting disease.

From the standpoint of incidence, we note that in this series the three most important symptoms and findings are:

1. Pain
2. Obstruction
3. Weight loss

Pathology

The character of the lesion was proved by microscopic studies in a very high percentage of the series either by biopsy, removal of the tumor, or autopsy. Adenocarcinoma or a colloid modification of such is usually found; occasionally an undifferentiated carcinoma. Removed nodes can not be labeled malignant or benign grossly, and at operation frozen sections should be done before determining with conviction that the case is inoperable.

Multiple polyposis has been noted in about 2

TABLE VI

Pathology Diagnoses	
Adenocarcinoma	107
Carcinoma Simplex	2

Others	2
Total	111

per cent of the cases of carcinoma of the bowel and the incidence of multiple carcinoma is rather rare.

Operability or Resectability

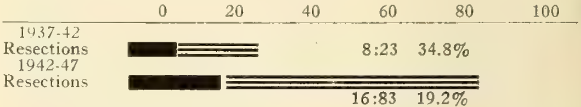
The above terms are relative ones. The attitude towards resectability has materially changed in recent years with gradual improvement in surgical principles, chemotherapy, preoperative preparation, et cetera. Operability has been extended to a remarkable degree, and even bearing in mind radical removal of possibly involved tissue, we have now arrived at the point where if the area can be mobilized, it may be removed rather safely. On the other hand, some have questioned the justification of radical operation in the presence of liver metastases. Nevertheless, a stormy convalescence in either of these cases is often justified by incredible periods of good health and well-being in a patient who is doomed.

Segments of the parietes are now removed with impunity but of course with a resultant higher mortality. The morbidity will also be greater, and both patient and doctor will sometimes wonder whether the effort to prolong life is worth while. The rate of cure is also decreased proportionately by the inclusion of these extensive operations. On the other hand, there is much to be said for a radical attitude. Not only does the patient have the best chance for a respite and a possible cure, but there is implanted in the mind of the young surgeon the correct viewpoint toward the increasing scope of surgery. In conclusion, resectability is probably a better term than operability.

The last chart was made to determine if the operative mortality has improved any in the last five-year period. The sulfonamides were in use in the first group and the second group had the additional aid of penicillin, sulfasuxadine, et cetera. Without any doubt, also, in the second five-year period there was better and more thorough preoperative and postoperative care.

Active interest in surgical management of malignancy of the large bowel has been more evident in the last twenty years. Anatomy and physiology, of course, have not changed, nor have all surgeons suddenly become experts, but no one doubts that surgical technique has increased the scope of resectability. Further benefits must come from earlier diagnosis, which obviously is lagging far behind surgical advances.

TABLE VII. NUMBER OF RESECTIONS OF CARCINOMA OF COLON AND OPERATIVE MORTALITY.



Multiple Stage 39

Others (Inhalation, Local, Intravenous)	56

Number of Surgeons 25

There are admittedly many different ways of attaining a certain surgical goal in a specific segment of bowel. The main prerequisite, however, is to do as extensive and radical an operation as possible without unduly jeopardizing the patient. Stating it differently, first the patient's life must be safeguarded; and second, the patient's health must be restored. This, if done by the open or closed method, by the one-stage or two-stage procedure, or by any other technique, makes little difference, provided the surgeon can show that his results from the standpoint of mortality and morbidity are equal to those of other techniques. Perfecting one technique is better than trying out every new surgical wrinkle that comes along. This is not the type of surgery that should be attempted alone by the occasional operator, but the aid of one experienced should be enlisted. If the 16,000 cases of carcinoma of the bowel were parcelled out equally to all surgeons, few would have sufficient experience to deal with them properly.

There are a variety of well thought-out operative procedures for patients with cancer of the colon. Those who champion one-stage procedures are apt to lay great emphasis on the benefits derived from prompt removal. This doesn't condone too great urgency. Obstruction, subacute perforation, or fixation must alter the course of the staunchest one-stage advocate. Graded procedures are needed for safety in this group. Many non-resectable lesions can be made operable by preliminary bowel drainage, and consideration must be given to exteriorization methods. So-called aseptic anastomosis versus open sutures must be critically weighed in each individual case.

In the final analysis, the main controversies in surgery of the colon revolve around: (1) the one or multiple stage procedure, and (2) the open and aseptic or closed method of anastomosis. Broadly speaking, as someone aptly stated, "less depends on the method than the manner of its execution."

Since there is considerable difference in the technique and the mortality rates in the extirpation of growths in the various segments of colon, it is desirable to discuss these regions separately.

The right colon is involved in this series in 30 per cent. Obstruction is seldom a problem here, and therefore decompression procedures seldom are necessary. The chance of survival is good due to the anatomic arrangement which makes it easier to include the entire lymph and vascular area in the resection. The terminal ileum and the right half of the colon must be included in the resection. The operative mortality in this group is relatively high. Charles W. Mayo does a one-stage with open anastomosis with a mortality of 8.4 per cent instead of the usual about 20 per cent. Lahey champions a Mikulicz type of resection as a primary operation, and closure of the complete fistula at a later date. His mortality is 13 per cent. Stone prefers a one-stage resection with aseptic anastomosis, and those operating at Massachusetts General have found that the mortality is less in the two-stage procedure. It is well to delay the preliminary ileo-transverse colostomy until the patient is in fine fettle from a preoperative standpoint. Sulfasuxadine or succinylsulfathiazole is a must and the Miller-Abbott tube should be used. Dangers of this operation are: (1) the usual double risk to two operations, and (2) obstruction of small bowel from herniations through the trap left by the ileocolostomy. This can be lessened by placing the anastomosis more than 12 inches from the ileocecal valve, thereby making the trap larger. Various methods have been suggested to manage the large, often infected, dead space resulting from resection of a large growth. Good drainage is very essential. The Mikulicz pack has enjoyed recent publicity and popularity.

Several procedures most commonly used for lesions of the transverse colon are resection and primary anastomosis, extraperitoneal resection, resection after preliminary cecostomy. Preliminary ileosigmoidostomy may be considered rarely, but may lead to an unnecessarily wide resection or may leave behind sizable defunctionalized segments of bowel. Primary resection is best adapted to lesions of the midcolon, and if the lesion is in the proximal third of the transverse colon, it can best be treated by the method used for the right colon.

We must always bear in mind the paucity of arterial blood at the distal end of the transverse colon, and if the resection is done in this virgin field, the bowel ends should be tested for viability.

The distal transverse, splenic flexure, and upper descending colon afford an ideal situation for a preliminary cecostomy followed by resection and aseptic anastomosis. A transverse incision is used well in this region. One may in some cases prefer Rankin's obstructive resection but immediate resection with anastomosis without preliminary drainage appears relatively hazardous in this region that is often obstructed.

The descending colon is involved the least. Representing one of the fixed areas of the colon, one cannot exteriorize the segment involved as easily as the sigmoid. Mobilization can be enhanced by dividing the suspensory ligaments to the splenic flexure. Obstructive resection has been popular at the Massachusetts General Hospital. Preliminary cecostomy, followed in ten days by resection and aseptic end-to-end anastomosis is the method of choice. There is some effort expended in closing the colostomy following obstructive resection, but preliminary cecostomy rarely requires surgical closure. In the absence of obstruction, resection with or without complementary cecostomy may be done. Complementary cecostomies heal more promptly than preliminary ones, due to the use of a small tube and shorter period of need for it.

For lesions of the sigmoid, although the operability is high and the operative mortality is low, the cure rate is considerably less than for the right colon. Lymphatic spread and earlier liver metastases account for this discrepancy. Many methods have been suggested to relieve the frequent and severe obstruction found at this site. The simplest and safest is cecostomy. If the growth is large or has produced an abscess by perforation, the cecostomy should be followed a few days later by a complete transverse colostomy. The Devine colostomy is rather well accepted in this country, but simple loop colostomy is becoming more popular. At any rate it is necessary to rest the infected bowel, and when possible to cleanse it preoperatively by means of irrigations.

The only price paid for safety and operability is the increased morbidity of additional hospital days. Many may be prepared for surgery without decompression and catharsis and enemas may be sufficient. Sulfasuxadine and succinylsulfathiazole are laxatives *per se*. Although it is the feeling of some that nothing more than such preparation is necessary before resection, many surgeons prefer decompression anyway. Whipple uses decompression frequently and Allen and Lahey do a preliminary tube cecostomy followed in about ten days by a Rankin obstructive resection. The use of a small catheter vent in the proximal segment placed near the clamp has been found helpful in this case.

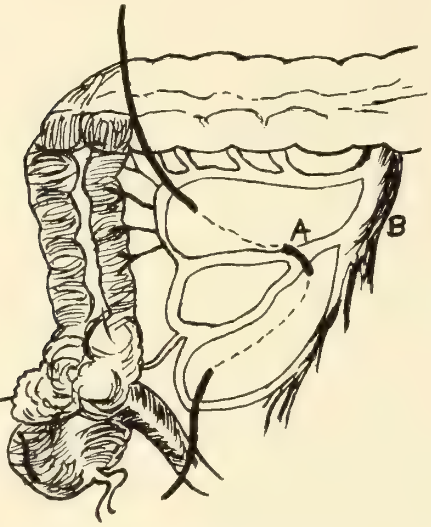

Fig. 3. The area of resection of the cecum with ligation of the ileocolic artery near the superior mesenteric at A. B indicates the main branch of the superior mesenteric which may be ligated inadvertently when an attempt is made to remove the lymphatic glands and which would result in death of a large part of the small intestine.

The history of surgery of the rectosigmoid and rectum is varied and interesting. Littre, in 1710, was one of the first to do a colostomy. Sixty years later a cecostomy was done, and in 1783, Duret successfully performed a left ilio-lumbar colostomy for an imperforate anus in a three-day infant. Then colostomy was not used in operations for extirpation of malignant lesions of the rectum till 100 years later when, in 1887, Shede did a preliminary colostomy for removing a tumor posteriorly and re-establishing bowel continuity. Until Miles presented his technique, in 1908, the surgical objective was extirpation and anastomosis of remaining segments to preserve the sphincteric mechanism. The emphasis was placed on the method of approach, i.e., perineal, sacral, anal, et cetera, and the degree of removal of the sacrum. The Kraske and Hochenegg procedures were in vogue. The Kraske was an end-to-end anastomosis of the sigmoid or rectum through a posterior approach without colostomy. The Hochenegg method was based on the principle of pulling the upper segment out through the anus and fixing it there with sutures. Colostomy was seldom done during this surgical era because the closure of a temporary colostomy was then accomplished by end-to-end anastomosis and carried a high mortality. Maunsell, in 1892, combined abdominal resection and perineal excision with sphincter preservation and posterior anastomosis. Miles modified the entire objective by minimizing the necessity for maintaining the sphincter mechanism and emphasized radical removal. He predicated this on the studies of the lymphatics of the rectum and concluded that the tumor also spread downward towards the anus. The compatibility of a colostomy with routine social, economic, and athletic activity was propagandized. Gradually, his teaching became universal. Nevertheless, in the past thirty-five years there have been sporadic attempts to develop operative procedures that would answer the need for wide excision and yet preserve anal continence. Lockhart-Mummery and Balfour in 1910 reported their experiences of anastomosis over a rectal tube.

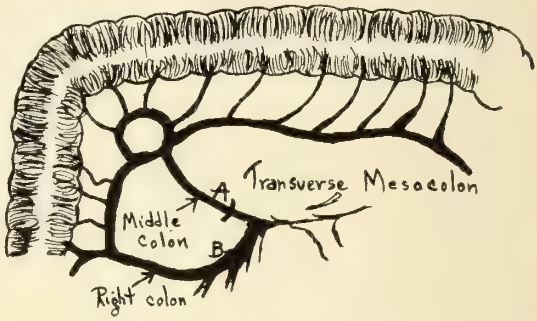

Fig. 4. In a certain number of cases where the left colic artery does not anastomose too freely with the middle colic part the splenic flexure, resection of the cecum and hepatic flexure may result in extensive devitalizing of the transverse colon when arteries are tied at A and B.

A new drive for eliminating the permanent colostomy was initiated in 1935 by Devine whose special transverse colostomy completely defunctionalized the distal colon, permitting later resection and anastomosis followed by closure of the colostomy. In 1937 Horsely resected the rectosigmoid after preliminary cecostomy and did an open anastomosis deep in the pelvis. Since 1939 reports have come from Babcock, Dixon, Fallis, Wangensteen and others, all with varying techniques but all with a common desire to eliminate permanent colostomy. This seems hopeful in the light of new interpretations in the mode of spread of carcinoma of the bowel. A half dozen investigators reveal that seldom is the spread by lymphatics or direct extension toward the anus. They think that a clearance of two inches below the tumor is sufficient. However, abdominoperineal resection is definitely indicated: (1) in widespread involvement of the sigmoid necessitating wide resection; (2) when the sphincters or levator muscles are involved; and (3) when the lesion is within three inches of the anus and encircles the canal (this may be debatable).

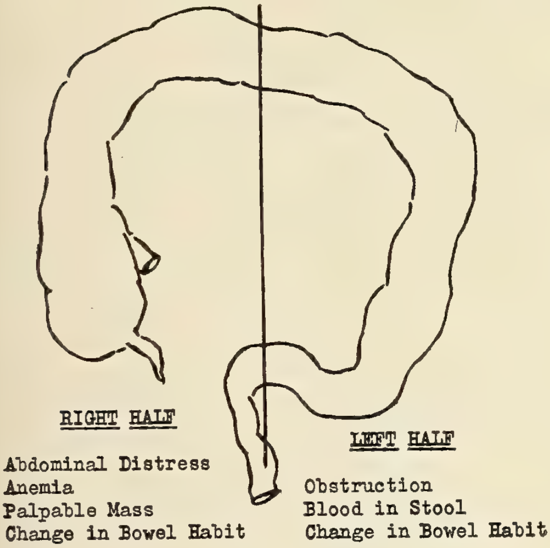

Fig. 5.

Summarizing, the temptation to make re-establishment of continuity the sole objective of the operation is one that must be guarded against if the surgeon is to avoid the most grievous of surgical sins, namely, fitting the patient to the operation rather than the operation to the patient.

General Complications

Complications of colon surgery are best brought out by another chart: Table VIII.

In closing, some general considerations to be stressed in bowel surgery may be briefly mentioned. Chemotherapy has proven a boon and preoperative sulfa and penicillin are a therapeutic necessity. Less sulfa is being used in the peritoneal cavity because of the liver damage often ensuing. Sulfasuxadine is a fine drug in this field because of its low absorption and toxicity and because of its laxative properties. Because of the antibiotics, complications such as abscess formation and wound infection are slow to appear and should be vigilantly watched for. The use of the Wangensteen and Miller-Abbott tube is indisputable and is only equaled by preliminary temporary cecostomy or colostomy. Intelligent use of the Miller-Abbott tube is paramount but a discussion of this is not within the scope of this paper.

TABLE VIII

Complications	Number	Per cent of 49	Per cent of Total
Peritonitis	6	13	5.5
Wound Infection	8	16	7.4
Pneumonia	9	18	8.3
Thrombosis	1	2	.92
Obstruction	9	18	8.3
Embolism	2	4	1.8
Others	14	29	12.8
(1) Coronary			
(2) Heart failure			
(3) Cerebral			
Total	49	100%	45.02

Delayed wound closure has been emphasized in this field. No matter how great care is exercised in the technique, these wounds have a relatively high incidence of infection. Coller's technique is to place the sutures, and then tie them and close the wound under pentothal anesthesia when no sepsis is assured, usually within seventy-two hours after resection. This practice has seldom been used at St. Mary's. Naturally, all the niceties and proprieties of preoperative and postoperative care are equally pertinent to this type of surgery.

In conclusion, bowel surgery will continue to pursue certain trends in the future as it has in the past. New techniques will replace the old. Many new drugs are just over the horizon, and consequently the tendency in recent years has been and in the future will be a steady decline in morbidity and mortality from the surgical aspect. May some panacea for early diagnosis be attained soon so that an ever increasing number of unfortunates will be spared the lot of death from cancer of the bowel.

BERYLLIOSIS

Brief Discussion and Presentation of a Case with Pulmonary, Digital and Axillary Node Involvement

ROBERT A. NACHTWEY, M.D., MALCOLM B. DOCKERTY, M.D.
and
CORRIN H. HODGSON, M.D.
Rochester, Minnesota

BERYLLIOSIS is a truly modern disorder. Though the metal beryllium was discovered in 1797, the first recognition of toxic effects was made in 1933[5] and the first report of beryllium toxicity in the United States was that of Van Ordstrand and associates in 1943. Beryllium was not extensively used until World War II. Because it resists corrosion and fatigue and increases the tensile strength of alloys, it is used in precision instruments, carburetors, airplane pipe lines and electrical instruments and in the coating of fluorescent tubing. Toxicity apparently does not arise from exposure to the ore beryl itself but from the fumes and dust encountered in extracting and processing beryllium. Therefore, toxic effects are seldom observed except in industries engaged in this work. Exposure to the occasional breakage of a fluorescent lamp is not a hazard unless one is cut by a piece of the glass which may cause a beryllium ulcer to form. Since June, 1949, all the major manufacturers of fluorescent lamps have discontinued the use of beryllium; so that this source of danger will eventually be eliminated. Because of the infrequency of berylliosis the condition is likely to be overlooked.

A brief review of the clinical aspects of berylliosis will here be given.

Dermatologic Manifestations

Within three to ten days after the initial exposure to beryllium fumes or dust, some cutaneous manifestations will develop in more than 25 per cent of the workers. A dermatitis may appear on the exposed parts of the body or a more or less generalized urticarial reaction may develop. The patient experiences a burning sensation or pruritus of the affected areas. The lesions respond well when the patient is removed from the offending environment and with the use of soothing and antipruritic lotions. The antihistaminic drugs are also thought to be helpful. Conjunctivitis may be associated with contact dermatitis of the face, but heals without complications.

A beryllium ulcer of the skin may develop if a minute crystal of beryllium enters through a cut or abrasion. A foreign body tissue reaction takes place which tends to ulcerate, heal and recur. This reaction evidently continues until the beryllium crystal is extruded or removed. Enlargement of the regional lymph nodes may be associated with the ulcer. Cuts from pieces of broken fluorescent tubing are a common source of beryllium ulcer. The treatment of this condition is excision of the region involved or incision and curettage to remove all traces of beryllium.

Respiratory Manifestations

Nasopharyngitis is an acute response to exposure to certain beryllium compounds. It consists of hyperemia and swelling of the mucous membrane of the nose and throat, and the patient notices soreness and bleeding. Ulceration, sometimes with perforation, of the nasal septum has been noted. The nasopharyngitis responds well when the worker is removed from the offending environment. It varies in severity.

Tracheobronchitis is an important development. It may exist without demonstrable pulmonary changes but it always precedes the development of pneumonitis. The symptoms associated with it are cough, dyspnea, occasional blood-streaked sputum, anorexia and loss of weight. No specific treatment is recommended, but failure to remove the worker from further exposure and failure to institute a strict rest program may lead to pneumonitis. When not complicated by pulmonary involvement the tracheobronchitis usually clears in four weeks or less.

Pneumonitis

Two forms of pneumonitis due to exposure to beryllium compounds are recognized, the acute and the chronic form. The acute form presumably results from a heavy exposure during a short period. The onset of symptoms is usually within a few hours or a few days after exposure. The patient complains of cough, dyspnea and substernal pain. The cough may be productive of small amounts of blood. With increase in the severity of

---

Dr. Nachtwey is a Fellow in Medicine, Mayo Foundation; Dr. Dockerty is with the Division of Surgical Pathology and Dr. Hodgson is with the Division of Medicine, Mayo Clinic, Rochester, Minnesota.

symptoms, the patient becomes extremely short of breath, cyanotic and bedridden, requiring oxygen. Anorexia and loss of weight are nearly always present. Unless influenced by complications the temperature and leukocyte count remain near normal. The acute pneumonitis runs a fairly rapid course ending in death or recovery in a few weeks or a few months. The mortality rate exceeds 10 per cent. At first no roentgenographic abnormalities are observed in the lungs. Later diffuse bilateral changes appear, progressing from a haziness to irregular areas of infiltration and then to conglomerate nodules before complete resolution takes place. Pulmonary fibrosis may remain after recovery.

Chronic pneumonitis follows prolonged exposure to beryllium compounds. It may appear after years of exposure and may fail to become manifest until a long time after exposure has terminated. The early symptoms, usually progressive, are severe dyspnea, anorexia, loss of weight, cough, fatigue and weakness. With the development of extensive pulmonary changes, notably fibrosis, cor pulmonale develops. If fever is present it is usually low-grade. Little if any alteration from the normal is noted in the laboratory examinations of the urine, erythrocyte and leukocyte counts, sedimentation rate, protein, or urea nitrogen. With the advent of right heart failure, secondary polycythemia may develop. Roentgenographic abnormalities of the lungs are described[2,3] as progressing from the earliest changes consisting of a "diffuse fine granularity" to a later distinctly nodular type of lesion. Some enlargement of the mediastinal lymph nodes is frequently present.

The treatment of both the acute and the chronic pneumonitis is the same and consists of rest in bed, oxygen when indicated, and supportive measures. Removal from exposure to beryllium compounds, of course, is essential. Antihistaminic drugs are said to be helpful. Penicillin may be effective in preventing secondary infection or in treating infection if it supervenes. BAL has been used in the treatment of berylliosis without appreciable effect.

Pathology of Berylliosis

Hardy and Tabershaw in 1946 studied necropsy material from a case of fatal chronic berylliosis and called attention to the presence of granulomatous reactions in the lungs, liver and lymph nodes. However, for the life history of the lesions as studied in the acute and chronic phases we are indebted to Dutra, who, in 1948, detailed the necropsy findings seen in some twenty cases in which patients had died from the effects of berylliosis. Death in the acute phase was brought about as a result of interstitial pneumonitis and hemorrhagic edema which effected a marked interference with the exchange of alveolar gases. Superimposed infections and failure of the right cardiac ventricle were precipitating factors.

Microscopically the lesions were not highly specific, although a peculiar fibrinoid change was described, the material being brightly eosinophilic and arranged in irregular or serpentine strands. In a few cases there were scattered giant cells and fibroblasts which in Dutra's opinion presaged the formation of granulomas and bridged the gap between the acute and the chronic lesions.

In "chronic" cases terminating fatally, there were, in addition to pulmonary fibrosis, sclerosis of the pulmonary vessels and emphysema, nodular lesions in the pulmonary parenchyma. Microscopically these nodularities featured tubercle-like structures of the so-called hard variety resembling more those seen in sarcoid than the ones which are typical of tuberculosis. In a matrix of brightly eosinophilic material, probably representing the fibrinoid substance previously referred to, were scattered fibroblasts, lymphocytes, histiocytes and giant cells. Histiocytes tended to be round rather than ovoid like the epithelioid cells of sarcoidosis. Prominent in the tubercules were peculiarly whorled or laminated purplish-staining structures which were termed "conchoidal bodies." Some of these bodies were located within giant cells while others were seen to be lying free. Caseation was absent. There was no increased content of silicon and, most importantly, analyses for beryllium gave positive results. The regional hilar nodes and occasionally the liver contained granulomas similar to those seen in the lungs.

Though one cannot make an absolute diagnosis of beryllium pneumonitis except by recovering beryllium from the lesion produced in the tissues, nevertheless, with a history of sufficient exposure, a characteristic clinical course, and typical roentgenographic findings, there should be no more question of the diagnosis than in obvious cases of silicosis.

The following case is one with typical beryllium pneumonitis, a "healed" beryllium ulcer of the finger and an associated enlarged axillary lymph node from which beryllium was recovered by spectrographic analysis.

Report of Case

The patient, a white man aged thirty-five years who lived in southern Minnesota, was admitted to the Mayo Clinic on April 7, 1949. He was engaged in the wholesale electrical business and stated that since 1936 he had spent much time in making fluorescent lamps, having blown the glass and coated the tubes.

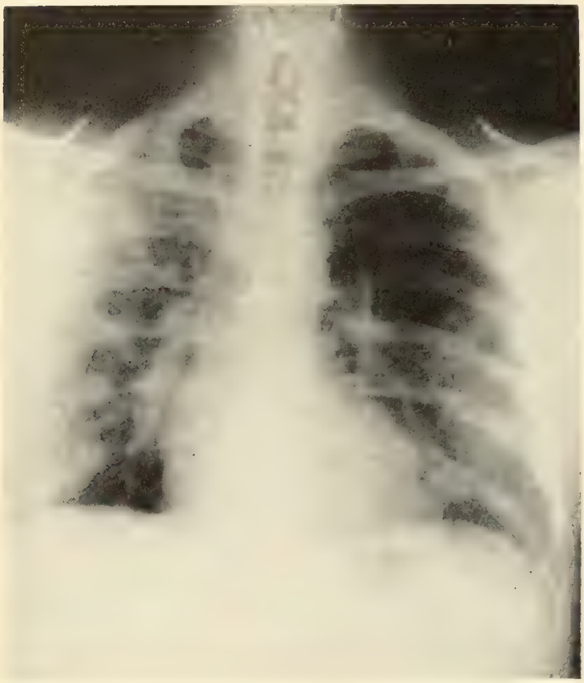

Fig. 1. Roentgenogram of the thorax of April 8, 1949 showing irregular consolidation in the peripheral portions of both lungs with enlargement of the hilar nodes.

His previous illnesses included an attack of what may have been rheumatic fever in childhood; pleurisy, dropsy and heart trouble in 1923; and pneumonia in 1923 and 1939.

For many years he had had a nonproductive cough which had increased in severity during the few months before admission. During the late fall of 1948 he had begun to notice dyspnea on exertion and fatigue. These symptoms had become progressively worse. He also had bilateral thoracic pain of pleuritic nature, and had noted pain in the lower dorsal region which was most noticeable in the morning and improved with activity. For several months before coming to the clinic he had noticed slight edema of the ankles, and for the previous two months, tachycardia and palpitation on exertion. He had never coughed up blood or experienced nocturnal dyspnea. During the two weeks before admission there had been a wheezing during inspiration. His weight had decreased from 205 pounds (about 93 kg.) to 187 pounds (about 85 kg.) in the preceding three months. Diuretics had been administered at home without appreciable effect on the edema or his symptoms. In 1945 while the patient was in the army a thoracic roentgenogram had been taken and apparently had been considered not to show any abnormality of the lungs. He presented a card from the chest x-ray survey reporting a film in 1948 as "negative."

His appearance when he was seated quietly did not suggest ill health. The color of his face and neck would darken when he lowered his head. He would become noticeably short of breath with slight exertion. There was no dilatation of the superficial veins of the neck. His heart was regular, the heart rate was 90 beats per minute, no murmur was detected, and there was no cardiac enlargement. Persistent fine râles were heard over the lower two-thirds of both lung fields. There was no clubbing of the finger nails, but a slight cyanosis of the nail beds could be seen. The liver and spleen were not enlarged and he had no edema of the extremities. At the base of the nail on the left fourth finger there was a healed scar which he said was the result of a lesion which would occasionally swell, drain some material, and then heal over. He thought this lesion had followed a cut by a piece of fluorescent glass. An abnormally enlarged lymph node was found in the left axillary space.

Laboratory examinations gave the following results: Hemoglobin, 14.8 gm. per 100 c.c. of blood; erythrocytes numbered 4,910,000 per cubic millimeter; leukocytes 6,600 per cubic millimeter, of which 51 per cent were neutrophils, 14 per cent monocytes, 27 per cent lymphocytes, 7.0 per cent eosinophils, 0.5 per cent basophils, and 0.5 per cent myelocytes. A smear of peripheral blood was reported to show a mild monocytosis but otherwise was not diagnostic of disease. Routine analysis of the urine gave normal findings. Though very little sputum could be obtained, examination of acid-fast stained smears showed no tubercle bacilli to be present. No tubercle bacilli grew on culture of two different specimens of gastric contents. No reaction occurred following the intradermal injection of 0.0001 mg. of tuberculin (PPD). The electrocardiogram was interpreted as follows: Rate 85, sinus rhythm; slurred QRS I, slight right axis deviation, diphasic P III, diphasic T III; V-1, inverted T; V-3, diphasic T; V-5, diphasic T. A roentgenogram of the chest was reported to show an irregular consolidation in the peripheral portions of both lungs and some enlargement of the hilar lymph nodes (Fig. 1).

On April 23, 1949, the enlarged left axillary lymph node was removed for pathologic study. Grossly the node exhibited a firmness suggestive of metastatic scirrhous carcinoma. The dry-appearing cut surface was of a mottled grayish-white color and it did not bulge.

Microscopically, under low magnification (Fig. 2) there was complete loss of nodal architecture and replacement by noncaseous tubercle-like structures, in a picture immediately identifying the lesion as a granuloma. The tubercles, which varied greatly in size, were isolated in some regions and conglomerate in others. With hematoxylin and eosin the bright pink staining of the tubercles stood out in marked contrast to that of the dark cords of lymphocytes in the surrounding nodal tissue. About every fifth tubercle contained one or more refractile dark purple staining acellular structures, the so-called conchoidal bodies. Giant cells were few.

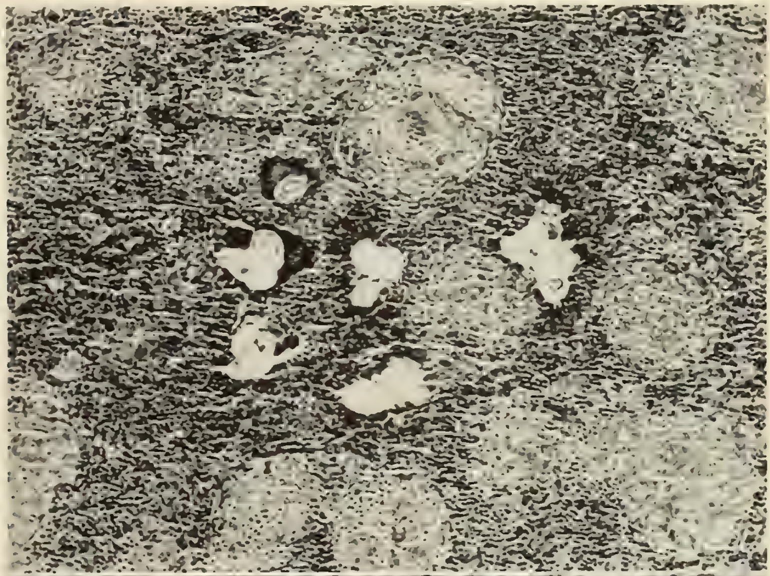

Fig. 2. The photomicrograph of the enlarged lymph node is typical of a granuloma with numerous "hard" tubercles which are pale-staining and lacking in necrosis. Giant cells are few. Conchoidal bodies appear in the clear zones (hematoxylin and eosin ×125).

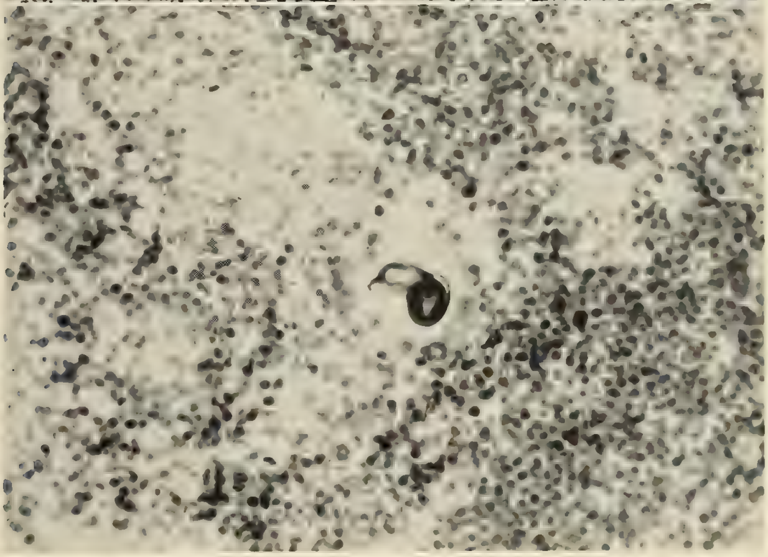

Fig. 3. Details of a tubercle showing the pale-staining histiocytes and one laminated dark-staining conchoidal body (hematoxylin and eosin ×285).

Under higher magnifications (Fig. 3) most of the pale cellular elements were seen to be histiocytes in a fibrinoid matrix which also incorporated a few plasma cells and lymphocytes. The conchoidal bodies appeared to be formed of a laminated particulate substance having some of the staining properties of calcium. They appeared similar to the structures occasionally seen in sarcoid, tuberculosis and regional enteritis, and they were not regarded as being specific for berylliosis. A portion of this lymph node was submitted to Dr. Frank Dutra of the Kettering Institute, Cincinnati, Ohio, for spectrographic analysis for beryllium. Dr. Dutra reported that his analysis of the specimen, which weighed 0.3 gm., showed the presence of 0.04 microgram of beryllium in the entire specimen.

The patient was advised to remove himself from all contact with beryllium powder or fumes, to undertake a rather strict rest program, and to avoid overexertion. He was last heard from in August 1950, at which time his condition was the same.

Because berylliosis is an uncommon disorder its presence is not likely to be suspected by the

BENIGN TUMORS, NEVI AND PRECANCEROSES

CARL W. LAYMON, M.D.
Minneapolis, Minnesota

VERRUCAE (warts) are of several different types, one of the most common of which is verruca vulgaris. These lesions occur most frequently in children on the exposed parts of the body, especially the hands. They may be single or multiple. In adults they tend to be fewer in number. Verrucae may occur any place on the body, even on the tongue and oral mucosa. Ordinary warts may occur under and about the nails in which locations they are especially difficult to eradicate.

Verruca plana (flat or juvenile warts) occur as pin-head sized or slightly larger, smooth, flat lesions which are usually multiple and occur on the face, neck, hands and knees. They are most common in children although they may occur in adults.

Verruca plantaris may be also single or multiple and unilateral or bilateral. The so-called mosaic wart represents multiple, contiguous lesions forming a plaque with a granular surface. The black dots on the surface of plantar warts represents capillary loops.

Acuminate warts are small, pointed projections which when multiple and coalescent form a large, vegetating mass. This type usually occurs in moist areas such as the ano-genital region, axillas or under pendulous female breasts.

Treatment:—Ordinary warts are best removed by destructive measures such as the actual cautery or electrodesiccation. In certain cases of periungual or subungual warts x-rays may be preferable. Other methods, usually less reliable, include chemicals such as acid nitrate of mercury, trichloracetic acid and salicylic acid. In multiple warts intramuscular injections of bismuth salicylate may be helpful. In flat, juvenile warts destructive measures are usually impractical. In these cases injections of bismuth, mercury protiodide orally and exfoliating topical applications such as lotia alba or sal alcohol may be effective. Plantar warts are best treated by means of x-rays (1500 to 2000r) sharply localized to the lesions. Destructive measures such as cauterization or desiccation may occasionally be necessary. Most acuminate warts respond favorably to a 20 per cent solution of podophyllin in alcohol or acetone. Cleanliness and dryness is important to prevent recurrences.

Fibroma

Fibromas are benign, connective tissue growths which occur as single or flat, sessile or pedunculated lesions of pinkish, ivory or brownish color. They may be soft or hard. Most cutaneous fibromas originate in the perineurium of the peripheral nerves, hence are in reality neurofibromas. Some develop from connective tissue fibers of the corium. The term Von Recklinghausen's disease has been applied to multiple neurofibromas. Excision is the preferred treatment for single lesions.

Glomus Tumor

These are peculiar vascular tumors usually located in the nail bed at the site of arteriovenous anastomoses which regulate the local and general temperature. Clinically the tumors are small, bluish and extremely tender and painful. The most satisfactory treatment is thorough excision.

Sebaceous or Epidermal Cysts

These lesions occur chiefly on the scalp, back and scrotum. They are usually fluctuant, tense swellings the size of marbles. The overlying skin is usually smooth and shiny. The content of lesions is cheesy in nature. Secondary infection is rather frequent. Some observers have claimed that malignant degeneration occurs in a small percentage of cases. Although there are various methods of treatment, surgical excision is effective.

Nevus Pigmentosus (Pigmented Mole)

Pigmented moles are of various sizes, shapes and colors. Hairs may or may not be present and the surface may be smooth or rough. Quiescent moles may be removed for cosmetic reasons or because they occur at sites of irritation. The term junction nevus has been applied to that type in which nevus cells occur at the epidermo-dermal junction. Clinically they are flat, smooth, hairless and usually dark. They are considered potentially malignant and should be

---

From the Department of Dermatology, Minneapolis General Hospital, Carl W. Laymon, M.D., Director; and the Division of Dermatology, University of Minnesota, H. E. Michelson, M.D., Director.

excised. Most benign moles can be adequately removed by means of destructive measures such as cauterization or desiccation. If a mole presents any sudden change in size, color or surface it should be widely excised.

Epithelial (Verrucous) Nevi

Such nevi are of epidermal origin and vary greatly in size, distribution, appearance and color pigment. Most of them are hairless. They frequently present a linear distribution. The term ichthyosis hystrix has been applied to localized multiple verrucous nevi, which are usually extensive and arranged in complex pattern. The preferred treatment is surgical removal whenever possible.

Vascular Nevi (Hemangiomas)

There are several types of vascular nevi. The port wine stain (nevus flammeus) is frequently unilateral and occurs usually on the face and neck, although it may appear anywhere. The lesions occur chiefly in infants and children, may be single or multiple and range in color from red to dark purple. They vary greatly in size and shape. They are usually smooth, but may be nodular on the surface. The general opinion prevails that the hazards of any effective treatment of port wine stains are so great that it is best not to treat them at all. There are certain preparations on the market which adequately cover them.

Strawberry marks (hemangioma simplex) are nevi in which large vessels are involved. They vary in size from a millimeter to several centimeters and in color from light red to scarlet or purple. They usually occur on the face, shoulders, scalp and neck, but may be found anywhere on the body. They tend to grow but frequently undergo spontaneous involution. Various methods of treatment have been used including injections of sclerosing solutions such as quinine-urethane, x-rays and radium, and solid carbon dioxide. Since so many of these lesions undergo spontaneous involution any form of treatment should be mild and expectant. Heavy doses of x-rays and radium are to be thoroughly condemned.

Cavernous hemangiomas are usually round, bright red or deep purple and spongy. As in other hemangiomas they occur most frequently on the head and neck but may be in other places. The lesions may be nodular, lobulated, polypoid or flat. Larger vessels are involved in this type of hemangioma. In general, the treatment is similar to that for strawberry nevi.

Leukoplakia

This is a precancerous lesion which represents a whitish thickening of the epithelium of the mucous membranes, especially of the lips, tongue and buccal mucosa. The lesions occur as superficial patches of various sizes and shapes. The surface is usually glistening and opalescent and often reticulated. There may be verrucous changes, erosions or fissures. Leukoplakia occurs chiefly in individuals past forty. Syphilis is only rarely an etiologic factor. Other predisposing factors are excessive smoking, poorly fitting dentures, jagged teeth and electrogalvanic currents between fillings and dentures.

In many cases observation is the only treatment necessary. Active treatment should be undertaken only if there is ulceration, erosion, fissuring or verrucous changes. Leukoplakia is radioresistant. Destruction with the cautery or desiccator under local anesthesia is frequently effective.

Radiodermatitis

Radiodermatitis must be regarded as a precancerosis. First degree burns are characterized by erythema with slight burning and itching which disappears after a few days or weeks. In second degree radiodermatitis there is edema, intense erythema and vesiculation followed in a few days by exudation and erosion and crusting. There is a loss of hair which may be permanent. Months later there may be atrophy and telangiectasia with excessive dryness of the skin followed by pigmentation, the formation of keratoses and later malignant degeneration. In third degree acute radiodermatitis there is extreme necrosis and ulceration with extremely slow healing which may take months.

In chronic radiodermatitis the skin is dry, thin, smooth, shiny and sensitive to trauma. There may be hyper or hypopigmentation. As the dermatitis progresses telangiectasia, keratoses and intense atrophy may develop. Ulceration which frequently develops into carcinoma is not uncommon.

Other disorders which may be complicated by malignant change include ulcers following burns or varicosities, lupus erythematosus and lupus vulgaris.

(Continued on Page 913)

THE EMERGENCY MATERNITY AND INFANT CARE PROGRAM IN MINNESOTA (EMIC)

A. B. ROSENFIELD, M.D., M.P.H.
Minneapolis, Minnesota

THE Emergency Maternity and Infant Care Program for the wives of servicemen in the four lowest grades, and for their infants during their first year of life, was developed as a part of the war effort during World War II. It was financed through the United States Children's Bureau and administered by the State Health Departments. In Minnesota, the program began in July, 1943. The maternal part closed in August, 1948, and the infant care part ended in June, 1949.

A total of 23,057 maternity cases received care in Minnesota at a cost of $2,238,050.10. The average cost per case was $97.07. There were 22,394 cases completed after delivery at an average cost of $46.44 for physicians' services and $54.25 for hospital care. Physicians attended all cases except for twenty-five attended by osteopaths, fifteen by midwives, and eight by others. There were 347 consultations, a ratio of sixteen per 1,000 cases, and fifty-eight cases required bedside nursing, a ratio of 2.6 per 1,000. Of all deliveries, 98.3 per cent took place in hospitals, with an average stay of nine days per case. This compares favorably with the state rate of 97.3 per cent but is lower than the hospitalization rates in the three large cities for 1948—Duluth 99.7 per cent, Minneapolis 99.4 per cent and St. Paul 99.0 per cent.

All medical and hospital care and immunization for infants were limited to the first year of life. The program provided for 7,515 infants at a total cost of $388,272.33, an average cost per case of $51.67. The average cost for physicians' services was $35.26 per case; for hospitalization it was $90.61 per case. Consultations were provided in 307 cases, a rate of forty per 1,000 cases. Bedside nursing was provided in thirty-nine cases or five per 1,000 cases. The average stay in the hospital was fifteen days.

Material and Method

The present study is based on a 10 per cent sampling of the 22,394 completed maternal cases, selecting every tenth application but excluding any incomplete or ineligible case. It should be noted that the number of applications is considerably greater than the completed cases, due to the fact that some incomplete cases were completed in other states and some applications were found to be ineligible under the regulations (Table I). This was especially true during the first year of the program. The entire data were obtained from the physicians' reports submitted to the State Department of Health. Neither the physicians' office records nor the hospital records were studied. The sample under consideration consists of 2,240 completed maternal cases. Infant cases are omitted because the services available were limited in extent and no follow-up was possible.

TABLE I. MATERNAL APPLICATIONS AND SAMPLE, BY YEARS

	Applications	Cases in Sample
July 6, 1943—July 5, 1944	8,440	547
July 6, 1944—July 5, 1945	7,912	725
July 6, 1945—July 5, 1946	6,374	703
July 6, 1946—July 5, 1947	1,775	224
July 6, 1947—August 1948	301	41
Total	24,802	2,240

TABLE II. SAMPLE OF 2,240 CASES FOLLOWED TO TERMINATION OF PREGNANCY

Received care in Minnesota	2,136
Known to have received care in another state	70
Termination before 20th week	33
False pregnancy	1
Total	2,240

The sample contains 2,136 cases that received full care in Minnesota (Table II), seventy that received part of the care in another state, thirty-three that terminated before the twentieth week, and one case of false pregnancy.

Consideration of the age of the mothers is quite interesting (Table III). Mothers in the age group of twenty to twenty-four years totalled 1,083 cases or 48 per cent of the sample. The usual proportion of maternal cases in this age group in Minnesota is about 30 per cent.

The fifteen to nineteen year age group included 14.5 per cent of the cases, in contrast to the usual 7 per cent in the state; 25 per cent in the twenty-

---

TABLE III. AGES OF MOTHERS IN MINNESOTA

	EMIC Program			Statewide
	No.		Percent	Percent
Under age 15	0			
15 years	2	325	14.5%	7.0%
16 years	14			
17 years	48			
18 years	95			
19 years	166			
20-24 years	1,083		48.4%	30.0%
25-29 years	554		24.7%	28.0%
30-34 years	142		6.3%	19.0%
35-39 years	30		1.3%	10.0%
40+	1		0.1%	3-4.0%
Not stated	105		4.7%	
Total	2,240		100.0%	

five to twenty-nine year age group, quite similar to the state proportion of 28 per cent; 6 per cent in the thirty to thirty-four year age group, compared with the state proportion of 19 per cent, and only one case in the age forty-or-over group, in which there are usually 3 to 4 per cent in Minnesota. The safest age groups are considered to be from fifteen through twenty-nine years of age. In the EMIC program, 88 per cent of all maternity cases were in this age group, whereas the state group contains only 67 to 68 per cent. On the other hand, in the age groups of thirty years and older, where the maternal mortality rises progressively, there were only 12 per cent in the EMIC program but 32 per cent in the state maternal cases. This factor was undoubtedly important in the low maternal mortality rate in the EMIC program.

TABLE IV. STAGE OF PREGNANCY AT FIRST ANTEPARTUM VISIT

Stage	No.
Unknown	3
6th wk. or earlier	77
7th wk.	73
8th wk.	84
9th wk.	111
10th wk.	135
11th wk.	104
12th wk.	108
13-16 wk.	350
17-20 wk.	319
21-24 wk.	267
25-28 wk.	230
29-32 wk.	197
33-36 wk.	126
37-40 wk.	56
Total	2,240

The mother's place of residence was in communities of 10,000 or more in 1,230 cases (55 per cent) and in communities of less than 10,000 population in 1,010 cases (45 per cent).

The records on stage of pregnancy at the date of the first antepartum visit are based on attending physicians' statements (Table IV). These records are of special interest, since such data are not readily available for obstetrical cases in Minnesota. Seventy-seven women visited their physician by the sixth week or earlier. The first prenatal examination was given in 695 cases (31 per cent) within the first three months of pregnancy. Within the first four and a half months pregnancy, 1,210 (54 per cent) had prenatal examinations. By the sixth month there were 1,631 or 73 per cent. On the other hand, 609 (27 per cent) did not have their first antenatal examination until after the sixth month, and fifty-six (2.5 per cent) until the ninth month of pregnancy, in spite of availability of medical care and the fact that the medical bill was being paid by the Federal government. Allowance must be made for the fact that prenatal care may have been obtained in another state, but this information was not supplied by the mother.

TABLE V. NUMBER OF ANTEPARTUM VISITS

Not clear	6
No visit before delivery	14
1 visit	48
2 visits	73
3 visits	129
4 visits	150
5 visits	181
6 visits	239
7 visits	314
8 visits	277
9 visits	219
10 or more	590

Antepartum visits to a physician totalled four or fewer in 400 cases, approximately 18 per cent of the sample (Table V). In 1,820 cases (81 per cent), five or more visits were made. Seven or more visits were made in 1,400 cases (62.5 per cent). Ten or more visits were made in 590 cases (26 per cent). Prenatal care was paid for separately with a required minimum of seven visits for the maximum fee. This factor may have contributed to the number of such visits. In the fourteen cases listed as having made no antepartum visits, five were first seen by the physician as "abortions," and eight were first examined at forty weeks. It is possible that prenatal care was given earlier outside of the state.

The duration of pregnancy was determined by the "expected date of confinement" which the physician entered on his report to the State Health Department (Table VI).

Thirty-seven cases terminated in an abortion at the twentieth week or earlier, and twenty-four cases terminated between the twenty-first and twenty-eighth weeks. A total of 1,911 cases (85 per cent) terminated between the thirty-ninth

Operation for ectopic	1	
Not clear or not reported	103	(4.6%)

* "Outlet" specified in 67 cases.

No complications occurred in 1,884 cases (84 per cent). There were 204 obstetric complications (9 per cent), 127 non-obstetric complications (5.7 per cent) and twenty-two both obstetric and non-obstetric complications. Details are shown in Table IX.

TABLE VII. ESTIMATED AND ACTUAL DURATION OF PREGNANCY IN FOUR "LONG PREGNANCIES"

Duration of Pregnancy	52 weeks	52 weeks	55 weeks	56 weeks
First antepartum visit	4-18-44	10-19-44	6-12-46	5-10-44
Estimated date of delivery	9-28-44	4-16-45	1- 2-47	8- 9-44
Actual date of delivery	12-21-44	7- 5-45	4-16-47	11-28-44
Duration of pregnancy on birth certificate	Term	40 weeks	Term	Term
Birth weight of infant	7 lb. 6 oz.	7 lb. 1 oz.	8 lb. 15 oz.	7 lb. 5 oz.

and forty-third weeks of pregnancy. It is of interest to note that in 103 cases (4.6 per cent), the duration of pregnancy was apparently from the forty-fourth to the fifty-sixth week. The frequent unreliability of the expected date of confinement by Naegele's rule, based on the last menstrual period, is evidence by a study of Table VII on the four longest pregnancies in comparison with a study of the birth certificates in these cases.

According to the physician's statement, there were 113 premature infants, or 5 per cent of the sample. Twenty pairs of twins were born, 0.9 per cent, or approximately one in ninety births, the usual ratio. There were no triplets nor quadruplets.

The type of delivery was not clear or not reported in 103 cases (Table VIII). Thirty-three were designated as "abortion" by the physician. Spontaneous delivery occurred in 1,681 cases or 75 per cent. If low or outlet forceps deliveries totalling 229 are added, plus eighty-two forceps deliveries where the type was not specified, about 89 per cent of the sample could be classed as spontaneous deliveries. There were forty-nine middle or high forceps cases, twenty-three versions and extractions, thirty-nine caesarian sections, and one operation for ectopic pregnancy.

TABLE IX. COMPLICATIONS

Not clear or no report		3	
No complication of any sort		1,884	(84.1%)
Only non-obstetric complications		127	(5.7%)
Only obstetric complications		204	(9.1%)
Any obstetric complication except infection, toxemia or hemorrhage	60		
Infection only	45		
Toxemia only	34		
Hemorrhage, shock or trauma	44		
Any combination of infection, toxemia or hemorrhage alone	7		
Any combination of infection, toxemia or hemorrhage with other obstetric complications	14		
Both obstetric and non-obstetric complications		22	(1.0%)
Infection, toxemia or hemorrhage involved	17		
No infection, toxemia or hemorrhage involved	5		

Malformations were reported in thirty-one cases (2.8 per cent) and birth injuries in ten cases (0.8 per cent). Deaths from malformations and from birth injuries have averaged over the past years approximately 0.3 to 0.4 per cent of all births in Minnesota. The reporting in this series, therefore, appears valid for congenital malformations, but the number of birth injuries is probably considerably under-reported.

Blood tests for syphilis were negative in 2,059 cases (Table X). There were seven cases giving positive tests, and these women were given anti-syphilitic treatment. In 109 cases or 5 per cent, no blood test was made, even though such tests are made by the State Department of Health free of charge.

TABLE X. ANTEPARTUM TESTS FOR SYPHILIS

Not clear or no report	65
Syphilis test not made	109
Syphilis test made:	
Negative	2,059
Positive and	
Treatment given	7
Treatment not given	0

One or more postpartum examinations were made in 97 per cent of all cases. No postpartum examination was made in seventy cases (3 per cent of the sample).

In this 10 per cent sample there were two maternal deaths. It would appear that by multiplying by ten we should get the full picture of the EMIC program. This is not true, however—at least not in the case of maternal deaths. Since two deaths occurred in the 10 per cent sample, there would be a total of twenty deaths in the total program or a maternal mortality of 0.9 per 1,000 live births. Actually, a total of only twelve maternal deaths occurred. In order to be able to compare the EMIC maternal mortality rate with the state rate, the four full years of the program (1944-47 inclusive) were studied. During this period the EMIC maternal death rate was 0.7 per 1,000 live births in contrast with a rate of 1.1 for the maternal cases in the state but not in this program, a significant difference of 36 per cent. It should be noted, however, that the EMIC live births included only 7 per cent of the total state births. A preponderance of mothers were in the safest age group of fifteen through twenty-nine (88 per cent in contrast to the usual 68 per cent), and the group was a favored one economically, since medical and hospital care were provided for the asking. Nevertheless, there is no question that adequate prenatal care, good obstetrical and postpartum care, consultations, blood, antibiotics, hospitalization, and public health programs play a significant role in the reduction of maternal mortality.

As a war effort, this program was actively supported by Minnesota physicians and hospitals. The excellent training of the physicians, the competent care rendered, and the adequacy of facilities are evident in the good results obtained There was considerable complaint about the burdensome paper work involved, a natural concomitant of government medicine, even though a determined effort was made by the State Department of Health to minimize the required work in this area.

BENIGN TUMORS, NEVI AND PRECANCEROSES

(Continued from Page 909)

Keratoses

There are several types of keratoses. The ingestion of inorganic arsenic may cause discrete, warty lesions which are usually symmetrical and occur most commonly on the palms and soles. Such lesions may or may not appear for several years after the drug has been taken. Arsenical carcinoma may complicate arsenical keratoses.

Verruca senilis (seborrheic keratosis) occurs as multiple, slightly raised light brown or dark brown, rough lesions which usually involve the face, back and chest. They are usually flat and covered by loosely attached, greasy scales which when removed show a raw pulpy base. Epitheliomatous degeneration is extremely unusual. Such lesions may be adequately treated by destructive measures such as cauterization or desiccation.

Senile keratoses occur chiefly in old people, especially those who have been exposed to the elements over long periods of time. This type of keratosis occurs especially on the exposed parts, namely, the hands and face. They may be single or multiple, discrete, flat, keratotic, grayish-brown or black lesions. They are much firmer, more discrete and more raised than verruca senilis. It has been said that squamous cell epithelioma develops in 20-25 per cent of the cases. Senile keratoses may be destroyed by desiccation or cauterization. They are radioresistant.

Cutaneous horns may resemble the horns of animals. In reality they are similar to senile keratoses except that there is an excessive development of horny material. They occur mostly on the scalp and face, although they may appear in other areas. Squamous cell epithelioma is not infrequently found at the base. The best method of treatment is by surgical excision.

History of Medicine In Minnesota

MEDICINE AND ITS PRACTITIONERS IN OLMSTED COUNTY PRIOR TO 1900

NORA H. GUTHREY
Rochester, Minnesota

(Continued from August issue)

John N. Farrand (1843-1880), "physician, surgeon and accoucheur," recently graduated from the medical school of the University of Michigan, arrived in Oronoco, Olmsted County, in the autumn of 1870.

A native of Franklin County, Vermont, John N. Farrand was born on a farm near Fairfield on August 2, 1843. He received his academic education in Fairfield, taught local schools for a time, and studied medicine under a physician of Fairfield. About 1868, on leaving for medical college in Michigan, he was married at Fairfield to Helen A. Butler, a daughter of E. S. and S. A. Butler of that place. His wife accompanied him to Ann Arbor.

At Oronoco Dr. Farrand bought a farm in Section 17 of Oronoco Township and there established his home, just outside the village. The house still stood in 1947, although changed from its original appearance. The first child of Dr. and Mrs. Farrand, Corydon Butler Farrand, was born in Ann Arbor. Four other children, Thomas S., Helen S., Albert M. and John were born at Oronoco.

Dr. Farrand was an able physician, a fine man and citizen, who won confidence and esteem in a widespread territory. Social-minded and public-spirited, he was a frequent speaker at public gatherings, an ardent Republican, a member of Oronoco Lodge No. 52 of the Independent Order of Odd Fellows, and for a time clerk of the independent school district of Oronoco.

On June 23, 1880, in his thirty-seventh year, Dr. Farrand died by accident. He and Dr. Marshall T. Bascomb, an Oronocan home on a visit, were fishing from a rowboat in Lake Shady, which was formed, then as now, by damming the Zumbro River at Oronoco. The water was high and the current strong. When Dr. Bascomb suddenly discovered that the boat had drifted and was at the verge of the falls above the old village millsite, he warned his companion and jumped. He escaped but Dr. Farrand was carried over the dam and was drowned. The funeral was conducted at Oronoco by the Odd Fellows of that village, Rochester, Zumbrota and Mazeppa in the presence of nearly 200 persons from surrounding countryside and villages.

In September, 1882, Helen Butler Farrand was married to M. M. Clark, of Oronoco, and she later removed with him to Canada. After the death of Mr. Clark the widow was married to an old acquaintance from Vermont. She spent the remainder of her life in California. The daughter, Helen S. Farrand, was married to George Echer, of Oronoco, in July, 1882. The sons, named in a former paragraph, for many years were residents of southern Minnesota.

In Oronoco the immediate professional successors of Dr. Farrand were

Dr. William A. Vincent, Dr. Edgar A. Holmes and Dr. Hamilton P. Boardman.

Corydon Butler Farrand (1870-1912), born on July 17, 1870, at Ann Arbor, Michigan, was the eldest of the five children of Dr. John N. Farrand and Helen Butler Farrand who came to Oronoco, Olmsted County, in the autumn of 1870.

Corydon B. Farrand, of brilliant native abilities and engaging personality, "a born doctor," as old friends have said, received his early education in the schools of Oronoco and Rochester. For a few years in the late eighties he taught district schools near Oronoco and in the autumn of 1890 he matriculated at the medical school of the University of Minnesota, from which he was graduated in 1893. In that day local newspapers commonly mentioned medical students as "doctors," so that during his undergraduate years frequent notes appeared in the press about the activities of Dr. C. B. Farrand. During vacations he studied and practiced medicine with Dr. Charles Hill, of Pine Island; on June 16, 1892, the *Olmsted County Democrat* stated that he had formed a partnership with Dr. R. C. Banks of Pine Island and would "hold forth in and around Oronoco."

In January, 1893, Corydon Farrand was married to Daisy Williamson, of Oronoco, who was then a high school student in Rochester. Mrs. Farrand continued her school work, in Minneapolis during her husband's last term at the university, and in Rochester. In later years she was a proficient teacher in the county schools.

On graduation Dr. Farrand began medical practice in Oronoco, in the honorable tradition of his late father. In that year, 1893, he spent some months in New York in postgraduate work, became a member of the Olmsted County Medical Society and the Southern Minnesota Medical Association and was appointed county physician in the townships of Oronoco, New Haven and Farmington. After 1894 Dr. Farrand practiced intermittently and at various places: in the East, at Red Wing, Goodhue County, at Hammond's Ford, Wabasha County, in South Dakota and in Minneapolis. He died in Minneapolis in 1912 at the age of forty-two years.

Lloyd Anson Faulkner, of Saint Paul, born in 1862, was graduated from the Bennett College of Eclectic Medicine and Surgery of Chicago in 1885 and was licensed in Minnesota on June 6, 1885, receiving certificate No. 1063 (E). He was in Rochester, Olmsted County, briefly in October, 1889, as the eighth appointee, as an assistant physician, to the staff of the Second Minnesota Hospital for Insane. His appointment was made during the reorganization of the hospital after the resignation of the superintendent, Dr. J. E. Bowers, and some of the assistant physicians. Dr. Faulkner, who had come well recommended by members of the medical profession of Saint Paul, began his work but after two weeks resigned and returned to Saint Paul. A few years prior to 1907 he was practicing in Lonsdale, Rice County; later he was in Hanley Falls, Yellow Medicine County; before 1916 he was again in Saint Paul, where he resided into the early nineteen thirties.

Charles Edward Fawcett (1869-1939), for forty-six years a leading physician of Olmsted County, at Stewartville, was born in the county, at Marion, in Marion Township, on October 13, 1869. Descended from Thomas Fawcett a Quaker who came to America in 1736, he was a son of John Henry

Preston Fawcett and Emily J. Wooldridge Fawcett and a grandson of Thomas Fawcett and Delia McCullock Fawcett.

In 1856 Mr. and Mrs. Thomas Fawcett came from Newcastle, Henry County, Indiana, to a farm home near Mabel, Fillmore County, Minnesota, accompanied by their four unmarried children, John Mahlon, Adoniram and Margaret, and by an older daughter, Mary, her husband Obadiah Stillwell and their two children. In 1858 the family group settled in Marion Township, Olmsted County. Thomas Fawcett died in 1878, his wife in 1888. Their son John H. P. Fawcett, born in Henry County, Indiana, on September 6, 1840, operated a farm one mile east of Marion for ten years; in 1866 he settled in the village, where for thirty-five years, an upright and useful citizen, he was a successful merchant and the village postmaster. The service he rendered the community as a dentist and as a helper to physicians from Rochester who attended the sick in Marion, was told earlier in this history. His marriage to Emily J. Wooldridge, native of Clearfield County, Pennsylvania, took place in 1867 in Sumner Township, Fillmore County. In 1900 Mr. and Mrs. Fawcett removed to Stewartville; their three children were Charles E., Arthur C. and Myrta (Mrs. George Leonard, of Harlingen, Texas, who died on December 6, 1944). Dr. Arthur C. Fawcett, who died in 1948, had been for forty-seven years a leading practicing dentist in Rochester.

Charles E. Fawcett was educated at the public schools of Marion, at Darling's Business College, in Rochester, and at the Winona State Teachers College. After teaching rural schools for two years, he began the study of medicine with Dr. Horace H. Witherstine, of Rochester, in the summer of 1891; that autumn he matriculated at the medical school of Northwestern University, for a course of three years. During vacations in that period he continued to work with Dr. Witherstine and he also spent considerable time as observer and occasionally as helper in the operating rooms of the Drs. Mayo at St. Mary's Hospital. He was graduated from Northwestern University with the degree of doctor of medicine on April 24, 1893.

Dr. Fawcett spent his first three months as a practicing physician in Austin, Mower County, and on December 18, 1893, took up his residence in Stewartville. On November 29, 1894, he was married to Myrta A. Phelps, of Marion, a daughter of Nathan S. Phelps and Margaret Waldron Phelps; Mr. Phelps and his wife were members of families who early settled in Olmsted County. To Dr. and Mrs. Fawcett were born four children: Gale C., Lois M., Frances E. and Donald N. Mrs. Fawcett died on July 7, 1910, aged thirty-nine years. In 1913 Dr. Fawcett was married to Mabel Bates Slater, of Stewartville.

Representative of the highest type of general practitioner and family physician, Dr. Fawcett was respected, trusted and loved. He gave unfailing response to all who needed him, was guide, philosopher and friend as well as physician to his patients, and was all his life a constructive citizen. He long served on the local board of education, for many years as president, and to him has justly been credited in large part the excellence of the Stewartville school system. His business acumen was evidenced during the thirty-two years (1907-1939) that he was president of the First National (later Stewartville National) Bank in the village. A loyal Methodist, like his forebears, he served on the official church board at Stewartville for forty-four years. He was an active Mason (A. F. and A. M.), Worshipful Master of the local lodge for four years, and a member of the Modern Woodmen of America. On December 18, 1933, the fortieth anniversary of his coming to Stewartville, the community honored him at a large reception, an account of which, with a summary of the tributes paid him by the men and women of the community and by Fellow physicians, is preserved in the *Stewartville Star* of December 21, 1933.

Dr. Fawcett, ethical, and loyal to his profession, was a member of the Olmsted County Medical Society from 1893, through its affiliation with other county medical societies, the Southern Minnesota Medical Association, the Minnesota State Medical Association and the American Medical Association. He served as village health officer and as county physician for his section. During World War I he was a captain in the United States Army Medical Corps from July 25, 1918, to January 3, 1919; at the Medical Officers' Training Camp, Fort Riley, Kansas, until August 12, 1918; then at Camp Beauregard, Alexandria, Louisiana; thereafter on assignment with the Seventeenth Sanitary Train. A charter member of the Ivan Stringer Post of the American Legion, at Stewartville, he served many years, until his death, as post chaplain. When death came, the captain, as was fitting, was accorded full military funeral rites, at Woodlawn Cemetery in the village.

Dr. Charles E. Fawcett died at his home, from coronary thrombosis, on December 8, 1939, survived by his wife and four children. In 1947 Mrs. Fawcett continued to reside at the family home in Stewartville; Gale C. Fawcett, credit man with the Standard Oil Company, was in Minneapolis; Lois M. Fawcett was head of the reference department of the Minnesota Historical Society, Saint Paul; Frances E. Fawcett (Mrs. J. R. Illingworth), a nurse, was in Spokane, Washington; and Donald N. Fawcett was general purchasing agent, the Flintkote Company, in Ridgewood, New Jersey.

F. L. Fletcher, physician and surgeon, who had his office in his residence on College Hill (the address, in 1947, was 406 Fifth Street, S. W.) practiced his profession in Rochester, Minnesota, from around 1860 to his death on January 22, 1870, at the age of sixty-two years. That his professional card appeared for the first time in the *Rochester City Post* of December 2, 1862, is not necessarily evidence of recent arrival: "The doctor is an experienced physician, well acquainted with the many diseases incident in the community, his treatment of which is already proved." Other notes bring out that he was a Presbyterian and a tireless worker for temperance. A final note is, "By the decease of Dr. Fletcher, a devoted circle of kindred has been deprived of one to whom they were most tenderly attached. The church has been bereaved of one of its most worthy and constant members and the community has lost a citizen whose character was without reproach and whose modest worth and many excellencies were appreciated most by those who knew him best." Mrs. Fletcher died in April, 1874, at Windom, Minnesota, where she had lived with her daughter Mary (Mrs. John Hyatt) since the doctor's death; her grave is in Rochester beside that of her husband.

In his reminiscences, several times quoted in this article, the late Charles Nicholas Ainslie traced the relationship between the families of Fletcher, Ainslie and Hagaman, all well known in Rochester and vicinity. The Reverend George Ainslie, Indian missionary, and pioneer Presbyterian minister in Rochester, first came to the city in December, 1861. His first wife, Mary Jane Hagaman, of Holland Dutch descent, the daughter of Nicolas Hagaman, of Hagaman's Mills, near Amsterdam, New York, had died in January, 1861, leaving two small sons. In September, 1862, Mr. Ainslie returned to Rochester from a trip east, bringing with him his bride, Mary Elizabeth Denny, of Thetford, Vermont, and his two boys, John and Charles. On arrival, because their home on a farm two miles north of Rochester was not completed, the Ainslies went to the home of Dr. Fletcher for a week or two. "In the Fletcher family were three grown children, Nick, deaf and dumb, Susan, who later (February 16, 1864) married my uncle Charles, [Mary] and Violet a younger sister . . ." Of the three sons of Charles E. Hagaman and Susan Fletcher, two became farmers in Olmsted County; the third, Dr. Edwin A. Hagaman, a dentist, in 1947 long had been established in practice in Rochester and, like his grandfather, had his office in his home on College Hill.

Dr. Fletcher's medicine and instrument chest for many years after his death was stored in the attic of the Hagaman farm home. Dr. Hagaman has described it as a "Boxlike affair made of boards over an inch thick, covered with cowhide, hair on, bound with leather strips fastened on with big brass tacks. The instruments and bottles of pills we used as playthings —sometimes we took a pill to see how it tasted or what it did to us. They were sugar-coated and tasted good."

Daniel O. Fosgate for a time in the late seventies lived on Cascade Road, Rochester, Minnesota, and was proprietor of the Rochester Dispensary, in the Williams and Pierce Block at the corner of Third and Main Streets. There he gave treatments for catarrhal colds and diseases of the throat and lungs. Dr. Fosgate's professional cards from August, 1878, into March, 1880, stated that he was the only regular, educated physician in Minnesota devoting exclusive attention to these affections, that he had the only known cure for catarrh. He was perhaps more successful as an inventor than as a physician. In 1878-1879 he perfected and patented a sulky plow, which at first was manufactured by the Rochester (Minnesota) Plow Works and later by the New York Plow Company. Three thousand of the machines were made in 1880 for Australian trade. The plow was followed immediately by Fosgate's Challenge Harness Buckle, duly patented, and produced by the O. B. North Company of New Haven, Connecticut. At this period Dr. and Mrs. Fosgate were much in the East and the doctor's cards disappeared from the Rochester press.

Frederick Edouard Franchere (1866-1934), eleventh appointee, as an assistant physician on the staff of the Second Hospital for Insane, came to Rochester, Minnesota, in the autumn of 1890 and served until the summer of 1892, when he resigned to enter private practice.

A son of Evariste and Martha Franchere, of French descent, Frederick E. Franchere was born at North San Juan, California, on July 14, 1866. He was graduated from the high school at Lake Crystal, Minnesota, in 1882, attended the state normal school at Mankato in 1883 and 1884, was graduated from the medical department of the University of Minnesota in 1890, and served as intern at the Minneapolis City Hospital.

In Rochester Dr. Franchere, dark, slender, keen, talented, of fine personality, made friends socially and professionally. As an able, ethical and humane physician he did valuable work at the state hospital and in leavng was honored by the entire personnel. In March, 1891, he became a member of the Olmsted County Medical Society; on his initial appearance before the group he read a paper on chloroform and ether as an anesthetic mixture.

From Rochester Dr. Franchere went to Sioux City, Iowa, where he remained three years before returning to Minnesota to practice general medicine and surgery, with special attention to the eye, ear, nose and throat, at St. James, from 1895 to 1902. In this period he was a railroad surgeon for two different roads and coroner of Watonwan County. In 1902 he returned to Sioux City to specalize in eye, ear, nose and throat work, a field in which he achieved distinguished success, as he did in the field of nervous and mental diseases.

Although Dr. Franchere's story from 1902 to 1934 belongs to the history of medicine in Iowa, a few points of interest are mentioned here. A constant student of medicine, Dr. Franchere traveled at home and abroad and contributed consistently to the medical literature. He was a member of county, state, district, national and special medical societies; a member and the secretary of the faculty of the old Sioux City College of Medicine, serving at different times as professor of neurology and professor of ophthalmology and otolaryngology; and he was on the staffs of four Sioux City hospitals. He was a member of St. Thomas Episcopal Church, of civic associations and fraternal organizations, and long was the director and secretary of the Sioux City Fine Arts Society. He was a skilled musician, an artist of note in oils and water colors, a student of astronomy, paleontology, ethnology and anthropology. Admired and respected for his abilities, he was loved for the warm kindliness and generosity toward his fellow creatures that distinguished him as early as his Olmsted County days.

Frederick E. Franchere was married on April 30, 1895, to Helen Catlin Hoyt, of Sioux City; he died on April 28, 1934, survived by his wife, two daughters and one son. In 1945 Mrs. Franchere was living in Sioux City. Mabel Catlin Franchere was the wife of Henry L. Kamphoefner, Professor of Architecture, University of Oklahoma, at Norman. Margaret Parrish Franchere was instructor in French in the Sioux City High School. Hoyt Catlin Franchere was associate professor of English at the University of Oregon at Eugene; Professor Franchere and his wife Ruth Frances have one daughter, Julie Victoire. Dr. Frederick W. Franchere, a native of Lake Crystal, Minnesota, and a nephew of Dr. F. E. Franchere, since 1911 has been (1947) a well-known practitioner in that city.

Hector Galloway (1828-1899), representative of the best in medicine and surgery of his day, was the first resident physician in Olmsted County and for twenty-four consecutive years was a leading member of the medical profession of the county. In the spring of 1855 he established his residence in the village of Oronoco, having first visited the site in March, 1854, with the three men from Allamakee County, Iowa, who founded Oronoco. In October, 1864, he came to Rochester.

Born in Mansfield Township, Cattaraugus County, New York, on June 28, 1828, Hector Galloway received his early education in the local schools. At the age of eighteen years he began teaching school at Ellicottville, and for several years taught in winter and studied medicine under a preceptor the remainder of the year. In 1852 he entered the Geneva Medical College, at Geneva, New York, from which he was graduated on completion of the required two courses of lectures. Shortly afterward he came to McGregor, Iowa, on the Mississippi River, where he practiced medicine until his removal to Oronoco.

Dr. Galloway spent nine useful years in Oronoco, practicing medicine ably under pioneer conditions and otherwise serving the region. A talented writer, he was chief editor of the *Oronoco Courier*, a seven column newspaper established by a group of Oronoco businessmen in the autumn of 1856, the first paper published in Olmsted County and conceded to be one of the best country newspapers in the state. The depression of 1857 together with the election the next year of Dr. Galloway and the local editor, E. Allen Power, as state senator and representative respectively, brought the paper to an end. Although the legislature did not convene that term, Dr. Galloway held his office and reported for work in January, 1860. He became superintendent of schools of Oronoco Township when the schools changed to the township system in 1860. With the coming of the Civil War he played an active part in local military affairs. When the citizens of Oronoco on April 25, 1861, met to organize the Oronoco Guards, of the Olmsted County Volunteers, Dr. Galloway was chairman, and later was fifer of the guards. On May 21, 1864, he was appointed surgeon of the Thirteenth Regiment, Minnesota State Militia, with rank of major, and thereafter was official examiner, at Oronoco, of persons claiming exemption from military duty. After he settled in Rochester, in October, 1864, he was for a time on duty on the Enrollment Board of the First Congressional District.

In Rochester Dr. Galloway first had his office in his home, a roomy frame house on Prospect Street (now Third Avenue, S. W.) opposite the site of the present post office. By June, 1866, he had rooms over the Woodard and Ells Drugstore on Broadway; again in his home in 1869; and from 1875 to 1879, in partnership with Dr. Francis A. Sanborn, in rooms facing on Zumbro Street, back of Hargesheimer's Drugstore.

Tall, handsome, vigorous, weighing 212 pounds (a weight that qualified him for membership in the social "Marrowfats," mentioned earlier in this chronicle), gentle and kindly, of superior culture and fine feeling, deliberate in diagnosis, on excellent terms with his colleagues, Dr. Galloway captured the fancy and won the affection and respect of the community. Venerable citizens recall, as do descendants of early residents, that he was the first physician who attended their families. His practice was comprehensive. He and Dr. W. W. Mayo often consulted together professionally and assisted each other in performing surgical operations. Today the consensus is that Dr. Galloway was a good physician and surgeon of unquestioned integrity. His sense of ethics was such, in fact, that it led to impatience with well-meaning persons who inquired too solicitously after their sick neighbors: Once in the Oronoco days as the doctor was returning with team and driver from a call at Genoa, a farm resident came running to the road, his arms flailing, to stop the carriage. "How is Mrs. . . . . . . ?" he called. "She's sick; drive on, Sam," said Dr. Galloway.

"His one fault," it is said, "was an incapacity to push himself forward to the station to which he was justly entitled." In 1866, for the second time a candidate for senator, he lost the campaign because, as he said, he could not travel around admiring pigs and kissing babies. He served, however, in various civic and professional capacities: member of the city board of health of Rochester with Drs. J. S. Allen and W. W. Mayo; county coroner at intervals from 1865 to 1873; school commissioner and member of the board of education from 1865 to 1867; a physician to the Olmsted County Poor Farm in 1870 and in county work thereafter; and as preceptor of medical students. He was a Mason, member of Rochester Lodge No. 21 (A. F. and A. M.) and a Knight Templar; he had the sword and probably the rest of the appropriate regalia and wore a Knight Templar charm on his watch chain.

Dr. Galloway's name figured in records of medical organizations. He was a founder, on April 15, 1868, of the original Olmsted County Medical Society; head of the committee on theory and practice of medicine and one of the committee to devise the first fee bill; and was a faithful contributor to discussions and debates, which covered a range of subjects from medicine and surgery to ethnology and physics. At a meeting on February 13, 1869, he read an essay on the philosophy of disease, in which, the *Rochester Post* reported, he announced "novel theories respecting the origin and progress of disease; the exposition abounded in apt illustrations and logical arguments in their support. Maintaining that all diseases have their source in interruptions of the process of nutrition, the doctor divided them into two classes, viz: first, those springing from causes extraneous to the system; and, secondly, those proceeding from vicious qualities of the organ itself . . ." Cancer, scrofula and consumption he named as examples of disease caused by imperfections of the oragnism in the task of nutrition. It was at this meeting that Dr. Galloway made his prophecy, still quoted locally in 1947, that the time would come when medical science would find remedies for all diseases but cancer.

Dr. Galloway became a member of the Minnesota State Medical Society on February 1, 1870, and for seven years was an active member, serving on various standing and special committees, submitting reports on typhoid fever, intermittent fever, diphtheria and German measles, and giving occasional reports of unusual cases seen in his practice. When the society met in Rochester in June, 1872, Dr. Galloway was active in the proceedings. After 1876 his name did not appear on the roster.

Not long after his arrival in Oronoco Hector Galloway was married there to Clarissa Alice Paige, one of the nine children of Mr. and Mrs. Foster Paige, pioneer settlers from St. Albans, Vermont. Two other Paige daughters were married to men who at some time were associated with medicine in Olmsted County; Caroline was the wife of George B. Ayres, of Rochester, a student of medicine under Dr. Galloway and later a prominent physician of Omaha, Nebraska; and Augusta, of Dr. Charles E. Teel, who from 1865 to 1880 was a leading physician of Olmsted County resident in Eyota.

Dr. and Mrs. Galloway had one child, Lucretia (Lulu) Maria Galloway, a beautiful and talented girl, who was married in Rochester, in October, 1878, to Dr. John Henry Spaulding, a native of Maine who came to Rochester from Sauk Center, Minnesota, a dentist who studied under Dr. J. M. Williams, Rochester's earliest dentist. In 1879 Dr. and Mrs. Spaulding removed to Fargo, Dakota Territory; their only child, Hector Galloway Spaulding, was born in Fargo on August 2 of that year. In October, 1879, Dr. and Mrs. Galloway also settled in Fargo, and there Dr. Galloway entered practice; On March 16, 1886, he was licensed under the territorial medical practice law of 1885. After some years in successful practice and in profitable speculation in lands in Dakota and western Minnesota he removed with his wife, about 1890, to Tacoma, Washington.

The fortunes of Dr. and Mrs. Spaulding affected the lives of Dr. and Mrs. Galloway. In 1886 Dr. Spaulding with his wife and his son went to Paris, France, for graduate study (his son has said, on the advice and encouragement of Dr. W. W. Mayo), and there remained, achieving a distinguished career as practicing dentist and professor of operative dentistry at the "Dental School of France." He retired in 1917. During World War I he was associated with the American Hospital in Paris and also worked with the Red Cross, as a captain, in a rehabilitation hospital for American soldiers which was housed in a castle near Bordeaux. He died in Nice in March, 1938. Lucretia Galloway Spaulding preceded her husband in death by forty-seven years; when she died in Paris in March, 1891, her husband and her son brought her body to Minneapolis for burial in Lakewood Cemetery. After her daughter's death Mrs. Galloway embraced theosophy and psychial research and in her investigations over a period of years traveled alone into many countries. Later she studied osteopathy in Chicago and became a licensed osteopath in Iowa and South Dakota and elsewhere, until in 1921 she went to Washington, D. C., to make her home with her grandson.

Dr. Galloway in the autumn of 1894 came back alone to Rochester, renewed his membership in the county medical society, and here again practiced medicine until May, 1895, when he returned to Oronoco, after an absence of thirty-one years. Failing in health and fortune, for about two years he made Oronoco his headquarters, spending winters with Dr. and Mrs. Ayres in Omaha. In 1897 he returned to Fargo, and early in 1899 to his boyhood home in New York. Dr. Galloway died on March 4, 1899, at the home of his brother in Otto, New York. His body was brought for burial beside his daughter's grave in Lakewood Cemetery, Minneapolis. His wife, Clarissa Alice Paige Galloway, died in Washington, D. C., in February, 1922; her ashes rest beside the graves of her husband and her daughter.

It has been said of Dr. Galloway, "If one can leave such a memory as he left in Rochester, his life is a success, though he dies in poverty and on charity. He instinctively practiced the precept, 'What we do for ourselves dies with us; what we do for others lives and is eternal.' He may have felt without realizing it that he was the only textbook that some people would ever read."

In 1946 Dr. Galloway had two living descendants: a grandson, Hector Galloway Spaulding and a great-grandson, John Henry Spaulding, II. Hector G. Spaulding, whose career was of absorbing interest to the doctor, was educated at the Lycée Janson de Sailly in Paris; at the Minneapolis Central High School and the University of Minnesota; and the Harvard Law School, from which he was graduated *cum laude* in 1903. After ten years of practice of law in New York, Minnesota and Illinois he taught law at Stanford University. Since 1920 he has been professor of law at

George Washington University. He was married in 1922 to Augusta de Laguna of Oakland, California; Mrs. Spaulding, a graduate in law, was in 1945 a lawyer for the National Labor Relations Board. John Henry Spaulding, II, in that year was with the American Army of Occupation in Japan.

Eric Olonzo Giere (1868-1942) was the twelfth appointee, in 1892, as an assistant physician on the staff of the Second Hospital for Insane at Rochester.

Dr. Giere, an eminent physician and surgeon of Minnesota, died on February 12, 1942, in Minneapolis, after fifty years in active practice. Many detailed accounts of his career have been published: in state histories, in records of numerous medical organizations and, particularly, in MINNESOTA MEDICINE, at the time of his death, and in the chronicle of medicine in Dodge County by Eckman and Bigelow. The present notes serve to link him to Olmsted County.

Born near Deerfield, Dane County, Wisconsin, on April 10, 1868, Eric O. Giere was a son of Ole Nelson Giere and Inger Himle Giere, both of whom were natives of Norway. His great-grandfather, Erick C. Himle, had been a physician at Voss. Inger Himle came to America in 1846 and Ole Giere in 1850; they were married in this country and made their first home on a farm near Deerfield, Wisconsin. In 1869 they came to southern Minnesota and settled in Vernon Township, Dodge County, adjoining Rock Dell Township, Olmsted County; in this community Eric O. Giere spent his youth and obtained his early education at the district school of Rock Dell a mile from his home.

Immediately on graduation from the University of Minnesota College of Medicine and Surgery on June 2, 1892, Dr. Giere came on appointment to the state hospital at Rochester, where he served three months. On July 6, 1892, at a meeting at the office of Dr. H. H. Witherstine, he became a member of the Olmsted County Medical Society. While in Rochester, on October 7, 1892, he received his license, No. 273 (R) to practice medicine in the state. In Rochester the young physician, ethical and loyal, made friendships among the local profession that were to be lifelong.

On leaving Rochester to enter private practice, Dr. Giere was first in Madison, Lac Qui Parle County; and subsequently in Hayfield, Dodge County; again in Madison, for seventeen years; in Watertown, South Dakota; in Saint Paul from 1921 to 1927; and in Minneapolis from 1927 until his death. He was survived by his wife, four daughters and four sons. The three sons who became physicians, Richard Waldorf Giere, Joseph Christianson Giere and Carl Norman Giere were associated with their father in the Giere Clinic, in Minneapolis, and since his death have continued the work. During World War II Dr. C. N. Giere and Dr. J. C. Giere were captains in the United States Army Medical Corps.

(To be continued in October issue)

President's Letter

ARE YOU AN 18 PER CENTER?

After the unpredicted 1948 election results, some of the political leaders in Ohio decided to pick a typical county and study the returns in an attempt to ascertain how and why the balloting went as it did. What they found out was what political scientists have constantly observed: that a light vote is not a representative vote, nor, more important, is it analogous with the principles of "by the people" government.

They discovered that many "responsible" citizens were irresponsible concerning this vital obligation of citizenship—among them 18 per cent of the physicians of that county and 22 per cent of the physicians' wives. This happened in Ohio; undoubtedly its counterpart was experienced throughout the country.

From an unAmerican vote has evolved an unAmerican shift to security planning, over-government and a decline in traditional personal freedom and initiative.

Now we have an opportunity to rectify some of the mistakes and omissions we have made in the last few years. It is possible, through individual responsibility and freedom to avoid collective security and control. Now and in the immediate future, the nation will be subjected to tremendous ideological assaults. We must have state and national legislatures composed of honest alert intelligent senators and representatives, who will be quick to recognize threats to our way of life and government and will move to avert those evils.

Your vote and the votes of your family and friends may be the pivotal point upon which an election return will swing. And, from there the consequences widen out into almost unbelievable areas; what began as a simple task—the marking of an election ballot—could well be the most important contribution you have ever made to the cause of democracy and good government.

F. J. Elias.

MORE PHYSICIANS IN SERVICE

WITH the onset of hositilities in Korea in June and the evident need for more fighting men, it became perfectly clear that Uncle Sam would need more medical officers. How many will eventually be needed is anyone's guess. The most equitable way of obtaining the additional medical personnel is a difficult problem to solve.

As has been frequently said those young physicians who have received their medical education at government expense have a moral, if not a legal obligation to enlist now that there is a pressing need. If all the members of this group were to enlist—an eventuality not likely to occur—the services would still need a certain number of reserve officers of experience in the various specialties and of various ranks.

By October 1, the Army will have recalled 1,582 reserve officers of the Army Medical Service, which will include 734 physicians. Recall quotas have been assigned to each of the six Army areas in the United States based on professional population rather than on the number of reserve officers in the area. Volunteers will be credited to the quota of the Army area in which they reside. To stimulate voluntary enlistment, medical officers who enlist will receive $100 a month above the usual pay for each rank.

Additional calls for enlistments in the near and and distant future will require additional professional personnel. To care for the 95,000 more men to be called to service in November an estimated 300 to 400 more doctors will be needed. More economy in the use of doctors in service than was evident in World War II will be employed; in the case of a 1000-bed general hospital only three physicians and two nurses will initially be called, the balance to stay in civilian life until receipt of warning orders for hospital deployment.

It is perhaps not surprising that enlistment of physicians has not supplied the need. Those who served in World War II and have only recently resumed private practice are naturally loath to pull up stakes and again don a uniform. Those who have never served have only a vague idea of the present and future need of their services. The present crisis does not have the appeal that a future need for an all-out effort may soon present.

It is not surprising that the AMA Board of Trustees went on record on August 12 approving the doctor-draft bills in principle. They, however, approve the drafting of physicians only for service in the war effort—not to care for veterans, civilian employes except outside the continental limits of the United States, or dependents of military personnel, except in case of dependents outside the country or in areas where adequate medical care cannot otherwise be provided.

To meet the present pressing need, Minnesota is required to furnish twenty reserve army doctors—a certain number of different ranks. Every effort is being made in the selection of these officers not to disrupt the civilian supply, nor intern, resident or postgraduate training. A committee of the Minnesota State Medical Association has been appointed to co-operate with the Military in order to cause as little disruption of medical training and practice as possible.

We may as well face the facts, however, that we must be strong in a military way, if we are to preserve our freedom and support the United Nations in its guarantee of the freedom of its member nations. A strong military force requires physicians.

BLOOD BANKS

THE EXTENT to which blood transfusion has come to be used therapeutically is strikingly brought out by the Survey of Blood Banks in the United States recently completed by the Bureau of Medical Economic Research of the American Medical Association under the direction of Frank G. Dickinson and Everett L. Welker.

At the time of this report, there were 1,648 blood banks located in 951 different cities in the country. In this number are included 1,571 hospitals, 46 non-hospital blood banks, and 31 Regional Red Cross Blood Centers. These centers have been increased from 31 to 34, according to last report. While about half of the hospital blood banks purchase blood and sell it to recipients, about two-thirds of these banks allow for replacement of blood from donors in lieu of payment for blood used. Some of the non-hospital blood banks make only nominal charges for the processing of the blood and count on voluntary donations of blood by members of civic groups for maintenance. The Red Cross Blood Centers do not purchase or sell blood and depend entirely upon donors for maintaining their supply. None of the centers administers blood, but distribution is free to hospitals which are allowed to make a nominal charge for handling. The cost of the processing and handling of the blood is borne by the Red Cross, which, of course, is supported by thousands of contributors.

The estimate of blood dispensed in a year is 2,532,452 units of 500 c.c. by the hospital banks, 306,130 units by the non-hospital banks and 427,565 units by the Red Cross. No estimate was made of the amount of plasma used. It is further estimated that all the blood banks and centers now have the equipment and personnel to bleed 5,500 donors simultaneously, or 440,000 in a forty-hour week. Thus the country seems pretty well supplied with facilities for obtaining and processing blood which can be easily expanded in case of an emergency. Possible future war need, of course, was in part responsible for the continuation of the Red Cross Centers. In case of a wide extension of the present Korean conflict, all the present facilities for handling blood would be vital.

The co-operation of the various agencies in Minnesota has been most satisfactory. Unfortunately, this has not been the case throughout the country. It is positively disgraceful that there should have been rivalry to the point of opposition between the American Association of Blood Banks and the Red Cross and that the Association has tried to put pressure on many State Medical Associations to instruct their AMA delegates to vote against approval of the Red Cross program. And this in spite of the precautions taken by the Red Cross of having the approval of the local medical societies before centers were established and in spite of the fact that in each state the program is controlled by a committee of the State Medical Association. The charge has been made that the Red Cross program smacks of socialized medicine. Since the program is supervised by medical societies and closely resembles in operation many of the independent blood centers, there would seem to be little excuse for the criticism. Fortunately, no resolution to discredit the Red Cross was even submitted to the meeting of the House of Delegates at San Francisco.

The wisdom of the establishment of the Red Cross centers would seem to be convincingly confirmed by the recent designation of the Red Cross as the official agency for the procurement of blood for the armed forces as in World War II.

Some ten years ago the Hennepin County Medical Society began discussing the possibility of establishing a central community blood bank in Minneapolis. Through the co-operation of a number of civic agencies, funds were collected, a building purchased and remodeled at 1914 LaSalle Avenue and on November 11, 1948, dedicated as a memorial to the service men of World War II who did not return. The bank began operating December 1, 1948, as the Minneapolis War Memorial Blood Bank. It is an independent non-profit organization. Blood is not bought or sold, and its supply is maintained in part by blood replacement on the part of relatives and friends of the recipients. Donor clubs have been formed, membership entitling the member and his family to free supply in case of need. The Center stocks the refrigerators of the hospitals of Minneapolis with various types of blood. A service fee only is charged for typing, Rh determination, and serology testing. The Minneapolis Blood Bank is willing to assist in setting up banks in neighboring communities with the approval of the local medical society and civic groups. How this was done in one specific instance is well told by Dr. Borgerson in the August issue of MINNESOTA MEDICINE (p. 773). Co-operation between such outlying centers and the Minneapolis War Memorial Blood Bank would be to mutual advantage.

Recently, arrangements have been made between the Red Cross Blood Center in Saint Paul and the Minneapolis War Memorial Blood Bank whereby an interchange of credit will be allowed between the two banks to patients entitled to blood from either bank. This example of a fine spirit of co-operation between two banks is highly commendable. After all, both institutions have the same purpose of providing a costly remedy, valuable in peace and war, at a nominal price within the reach of everyone.

MEDICAL ECONOMICS

Edited by the Committee on Medical Economics
of the
Minnesota State Medical Association
George Earl, M.D., Chairman

FSA CALLED SEED BED OF SOCIALISM

Beginning a new series on seed beds of socialism, a recent issue of *Nation's Business* calls the Federal Security Agency an "unknown visitor in the life and home of every American . . . well on its way toward changing the individual thinking as well as the social, economic and political structure of the nation."

Comparing it to other federal departments to convey the scope of the agency's control, the article says:

> "It reaches every citizen, either in benefits or in taxes. Among older departments, State is concerned with foreign affairs, Commerce with trade, Labor with workers and employers, National Defense with military security and Agriculture with one class of producers. Only Federal Security is all-embracing in its relation to the human beings who make the nation.
>
> "Other nations are solicitous for the welfare of their people from the cradle to the grave, but this agency goes farther. It gives prenatal advice for babies, guides them later through childhood, cares for workers and aged and succors the relicts of the departed."

Aim to Create Socialist State

Unpopular as the idea of socialism is, some of the key supporters of the agency and what it stands for have shamelessly confessed that its chief goal is to establish a welfare state:

> "Some of its key employes and ardent supporters have declared frankly the final goal of this pretentious agency is to abolish the present democratic form of government and to create a socialist state where officials will be dominant over the individual and his activities—in the home, in trade or in security—the attractive name so often used—while the youth are indoctrinated for the future."

The List Grows Longer

Helping this "all-embracing" agency to indoctrinate youth is a budget in 1950 which is larger than that of any other federal department except National Defense—$1,591,000,000. Its organization includes 35,363 full-time and 4,127 part-time workers; it has twelve regional offices and many National Institutes of Health and Health Workshops in cities and towns.

The number and variety of divisions and bureaus which it administers seems phenomenal, and, if the most ardent supporters of government control have their way, the list can extend almost endlessly. The Federal Security Agency administers Social Security which includes Public Assistance, Old-age and Survivors Insurance, the Children's Bureau, and Federal Credit Unions; Employes' Compensation; Public Health Service including quarantine and 20 odd hospitals; a printing house for the blind in Louisville; Food and Drug Administration; Vocational Rehabilitation, and the Office of Education. In Washington it operates two big public hospitals—St. Elizabeth's and Freedmen's—Howard University for Negroes, Gallaudet College and Kendall School for the Deaf.

Keynote Found

With these and many more institutions and agencies under its wing, and with an annual distribution of $1,000,000,000 to states, "FSA is in position to punish any state—almost any citizen—that dares to challenge any of its policies or directives." Looking through the manual of the Social Security Agency, the keynote of these policies is made clear:

> "Social security and public assistance are a basic essential for attainment of the socialized state envisioned in democratic ideology, a way of life which so far has been realized only in slight measure."

If this is "only in slight measure," Americans can well ask, "What is considered a completely full measure?"

CONGRESSMAN DISCUSSES SOCIALISM —AMERICAN VARIETY

Adding warning and emphasis to the example of the type of controls which the Federal Security Agency is slyly developing, Congressman Ralph W. Gwinn, New York, spoke at a meeting of the Medical Society of New York recently, quoting noted witnesses to testify that socialism is creeping surely into American life.

Mr. Gwinn quoted "America's greatest living Socialist, Norman Thomas," whose words underscore the fact that socialist trends are the greatest threat ever to come on the American scene. Running for the presidency since 1928, Mr. Thomas was somewhat pleased in 1936, after four years of the New Deal, that it "had in some fashion carried out our immediate demands."

Mr. Gwinn cited the words of Communist leader, Earl Browder, declaring that American capitalism can deteriorate into socialism, thence to communism, unless Americans are vigilant:

> "State capitalism leaped forward to a new high point in America in the decade 1939-1949. It became overwhelmingly predominant in every major phase of economic life, and changed the face of politics. State capitalism has progressed further in America than in Great Britain under the Labor Government, despite its nationalization of certain industries, which is a formal stage not yet reached in America; the actual, substantial concentration of the guiding reins of national economy in governmental hands is probably on a higher level in the U. S. A.
>
> "The general trend to state capitalism signifies a yielding of capitalist private ownership for more socialized forms of the economy and results in a more socially organized economy. . . . Each important measure of state capitalism is a part of the whole movement which results in the socialist transformation.
>
> "State capitalism is the invasion of planned production and points the way to Socialism. . . . The U. S. Government has emerged as the greatest trust of all, the super-trust whose economic operations dwarf the largest private corporation. . . . The trend to state capitalism marked the final monopolistic stage. After monopolistic capitalism the only higher stage possible is the fully-socialized society."

And, the late leader of British Socialists, long noted for his authoritative statements on socialism and what causes it, was also quoted by Mr. Gwinn. Harold J. Laski says:

> "Since it is the Socialist belief that the central principles of the New Deal have come to stay, the Socialist Government in Britain can have the confidence that America will advance in a collective direction and at an increasing tempo."

Another of the greatest contemporary authorities on the subject of economic socialism and communism has declared that leftist policies are more evident in America than in western Europe. John Strachey, England's War Minister, helps Mr. Gwinn's argument by saying:

> "Outside the United Kingdom and the Scandinavian countries, the U. S. Administration today is probably more to the left in general economic policy and point of view than any of the governments of western Europe."

The "Scare Words" Again

Supporters of federal medicine, increasing social security and the whole gamut of expanding government control measures can ridicule the use of such terms as the "welfare state" and "socialism" by calling them mere "scare words," like President Truman did, not long ago. Many of them would think twice after reading a new booklet written by former Senator Joseph H. Ball entitled "Where Does Statism Begin?" The pamphlet points out that the welfare state is a state in which the government assumes and tries to carry out the responsibility of assuring a certain standard of living and economic security for everyone in terms of housing, food, clothing, health services and education, regardless of the individual's age, ability, productive effort or moral deserts."

Words which have gained new definitions through common usage receive comment in the pamphlet:

> "Statism is the concentration of more and more power in the hands of government as an inevitable result of trying to substitute government planning of production, distribution, and pricing for the free market mechanism of capitalism.
>
> "Socialism, welfare state and statism are interchangeable to this extent: their political and economic promises can't be carried out without new and extensive concentration of power in the hands of the central government."

Defining Not Enough

Individual Americans, states *New York Medicine* recently, will realize that mere definition of words is only the beginning of understanding:

> "There is a price tag on human liberty and freedom in any human endeavor. That price is the willingness to assume the responsibility of being free men. Payment of this price is a personal matter with each of

us. It is not something we can get others to pay for us. There is a very human impulse to let others carry the responsibility of freedom, and the work and worry that accompany it—while we share only in the benefits!

"In these present days, power is, wittingly or unwittingly, conferred by a people upon others. Ofttimes it appears as if this power were forcibly wrested away, but it is not. People give their freedom away. By vote we give away our hard-won rights. Factors, which bring a change, most frequently go unnoticed because of apathy. Only when an evil is firmly entrenched do we become aware of its insidiousness. While an evil is quietly and unobtrusively establishing itself, people go about their business, performing their daily tasks saying: 'This can't do that to us,' and all the time it is being done . . . right under their noses!"

Julian F. Dubois, M.D., Secretary

MINNEAPOLIS MAN PAYS $100 FINE FOLLOWING CONVICTION FOR VIOLATING FEDERAL FOOD, DRUG AND COSMETIC ACT.

Re. United States of America vs. Otto W. Dressler, an individual trading as Gold Seal Laboratories.

On June 12, 1950, Otto W. Dressler, seventy-two years of age, 204½ 10th Street South, Minneapolis, paid a fine of $100 in the United States District Court at Minneapolis, following his conviction by the Hon. M. M. Joyce, of violating the Federal Pure Food and Drug Act. Dressler was convicted of "having unlawfully shipped in interstate commerce a certain device, to-wit, Polizer, in violation of the Federal Food, Drug and Cosmetic Act, in that said device was misbranded within the meaning of 21 U.S.C. 352 (a)." The information filed by the Government alleged that accompanying the device was a circular entitled: "The Pol-izer (Miracle of the Age) Why Suffer." The information also alleged that the statement represented and suggested that Polizer was efficacious in the cure and treatment of over 60 ailments from arthritis to heart trouble. It was the contention of the Government that the device was misbranded because it was not in fact efficacious in the treatment of such ailments.

In finding Dressler guilty, Judge Joyce stated that expert witnesses of the highest rank in the State of Minnesota had studied and tested the device and found it wholly useless and of no therapeutic value. Judge Joyce further stated that not one scintilla of evidence was produced by the defendant that there is any penetration into the human body of any of the so-called elements of the Polizer or of polized water.

The case was tried for the Government by Mr. Clifford Hansen, Assistant United States Attorney of Saint Paul. The preliminary work in the case was done under the direction of Mr. Chester T. Hubble, Chief, Minneapolis District Pure Food and Drug Administration.

MINNEAPOLIS WOMAN SENTENCED FOR CRIMINAL ABORTION

Re. State of Minnesota vs. (Mrs.) Val A. Ramer.

On August 22, 1950, Mrs. Val A. Ramer, seventy-six years of age, 809 Douglas Avenue, Minneapolis, was sentenced by the Hon. Rolf Fosseen to a term of not to exceed three years in the Women's Reformatory at Shakopee, Minnesota. Mrs. Ramer had entered a plea of guilty on June 6, 1950, to an information charging her with the crime of abortion. Mrs. Ramer also admitted a previous conviction in 1936. Because of the defendant's age, Judge Fosseen suspended the sentence and placed the defendant on probation for a period of five years. Judge Fosseen warned Mrs. Ramer that not even her age would save her from going to the Women's Reformatory if she became involved, in any manner, in any further violation of the laws of the State of Minnesota.

Mrs. Ramer was arrested on May 4, 1950, by Minneapolis police officers following the hospitalization of a twenty-one-year-old Minneapolis woman suffering from the aftereffects of a criminal abortion. The Minnesota State Board of Medical Examiners was asked to assist in the case and legal counsel for the Medical Board obtained a signed statement from Mrs. Ramer in which she admitted having performed the abortion by means of a probe and packing the cervix with gauze. Mrs. Ramer also admitted receiving $150 for her services. The abortion was performed in Mrs. Ramer's apartment. Mrs. Ramer also admitted that she had performed other abortions averaging about one per month. Mrs. Ramer was convicted by a jury in the District Court of Hennepin County on April 24, 1936, of the crime of abortion. At that time, a Minneapolis physician, now deceased, was also convicted with Mrs. Ramer. Mrs. Ramer holds no license to practice any form of healing in the State of Minnesota.

HEALTH RESOURCES ADVISORY COMMITTEE

Dr. Harold S. Diehl, dean of the medical sciences at the University of Minnesota, has been named to the new Health Resources Advisory Committee of the National Security Resources board. The appointment was made by W. Stuart Symington, chairman of the board.

Purpose of the committee is to assist and advise the National Security Resources board on problems of the nation's health relating to national mobilization and in the event of an atomic war.

The commitee also may be given the added responsibility of advising Selective Service in the drafting of doctors.

Dr. Diehl attended a meeting of the committee in Washington Thursday and Friday, September 7 and 8.

American Medical Association

House of Delegates—Summary of Proceedings

San Francisco—June 26-30, 1950

First Meeting, Monday, June 26

Morning Session

The House of Delegates convened in the Concert Room of the Palace Hotel, San Francisco, and was called to order at 10 a.m. by the Speaker, Dr. F. F. Borzell.

After preliminary proceedings including adoption of the minutes of the interim session, roll call, appointment of a Vice Speaker pro tem, in the absence of the Vice Speaker, invocation and the appointment of tellers for the session, the House heard the address of the speaker giving general directions for reference committees and delegates. He then presented the reference committees to the House.

The House then chose Dr. Everts A. Graham, St. Louis, as the recipient of the Distinguished Service Award for 1950. This was followed by the address of President Ernest E. Irons who summed up the progress made against infiltration of socialistic trends by saying, "We as physicians and citizens shall not relax until, with other patriotic groups in business, on the farm, in the other professions and labor, we shall have rolled back the socialist flood that threatens to engulf our American freedom and our solvency."

The Chairman of the Board of Trustees, Dr. Louis H. Bauer, presented the report of the Board. Ordinary income in 1949 exceeded costs and expenses by $106,817.56; this amount was credited to the capital account of the Association, which now totals $4,240,197.81.

The report of the Board of Trustees also included reports of, and concerning, the Committee on Displaced Persons, Committee on General Practice, Council on National Emergency Relief, Student American Medical Association, Commission on Chronic Illness, Co-ordination Committee on Legislation, Treasurer, Auditor.

All recommended resolutions were referred to reference committees.

Dr. Elmer L. Henderson, chairman of the co-ordinating Committee, presented the report of his committee.

This was followed by the report of the Council on Medical Service, given by Dr. James R. McVay.

Dr. Harvey B. Stone, acting chairman, presented the report of the Council on Medical Education and Hospitals.

The House recessed at 12:30 p.m.

Afternoon Session

The House reconvened at 1:45 p.m. and heard a supplementary report of the Board of Trustees, read by Dr. Bauer, which included the report of the Committee on Hospitals and the Practice of Medicine.

This was followed by a Report of the Committee on Chronic Diseases. In view of the work of the Commission on Chronic Illness, there had been suggestions that the functions and work of the two bodies had been overlapping. After hearing evidence of the necessity of both bodies, the House voted continuance of the committee.

The House then heard the proposed resolutions, all of which were referred to their respective reference committees for study and such committees will report the resolutions to the House for approval or rejection.

The House recessed at 3:45 p.m.

Second Meeting, Tuesday, June 27

Afternoon Session

The meeting convened at 1:20 p.m. The House adopted a report of the Committee on Executive Session, which stated that an executive session to discuss a resolution on expenditure for advertising was not necessary.

Dr. Bauer read a message wishing the House a successful meeting from Dr. T. C. Routley, Secretary General of the Canadian Medical Association. The House requested the Secretary to wire appreciation to Dr. Routley.

The House recessed at 1:30 p.m.

Third Meeting, Wednesday, June 28

Morning Session

The meeting reconvened at 9:10 a.m. The House adopted the report of the Reference Committee on Reports of Officers which included a recommendation from the Speaker's address that an interim committee on constitution and by-laws be appointed.

The House adopted a resolution eliminating oral reading of its voting, substituting the use of tellers' reports directly to the speaker who then announces the vote.

The House next considered the report of the Reference Committee on Reports of the Board of Trustees and Secretary. The report of the Board was considered by section:

Section 1. Financial statement—approved.

Section 2. Committee on Displaced Physicians—approved.

Section 3. Student American Medical Association—approved and established.

Section 4. Survey of Physicians' Incomes—approved with minor amendments.

Section 5. Surveys of Medical Education and Medical Practice in Great Britain—approved with commendation.

Section 6. Hearings on Taft and Hill Bills—approved.

Section 7. Resolution on Free Choice of Physicians for Federal Employes—approved recommendation for more study and information.

Section 8. Expansion of Washington Office—approved action to increase efficiency and continue implementation.

Section 9. Bulletin for Woman's Auxiliary—approved cancellation of bulletin.

Section 10. Treasurer's and Auditor's reports—approved.

Section 11. Quality of Medical Care in a National Health Program—approved Board's action in expressing strong opposition to the socialist blueprint for medical care of the recommendations of the Subcommittee on

Medical Care of the Committee on Administrative Practice of the American Public Health Association.

Section 12. Resolutions on Medical Care of Veterans —approved statement that this resolution reaffirms previous similar resolutions of the House in opposing unjustified care being given to non-indigent veterans for non-service-connected disabilities.

Section 13. Resolutions on Purveyal of Medical Service, Resolutions on Report of Committee on Hospitals and the Practice of Medicine, Resolutions on Enforcement of Principles of Medical Ethics and Resolutions on Practice of Medicine by Hospitals—approved all these resolutions having to do with the purveyal of medical services and the practice of medicine in hospitals.

Section 14. Report of the Committee on Hospitals and the Practice of Medicine—approved report which provides that if a physician is found to be unethical through proper authorities and is still retained on the staff of any hospital approved for resident or intern training, it shall be the duty of the Judicial Council to show cause why hospital should not be removed from the approved list, assuming the hospital is just as unfit for the training of physicians for unethical reasons as it is unfit if it does not have proper filing systems. The report also recommended recognition of the practice of anesthesiology, pathology, physical medicine and roentgenology as practice of medicine.

The House next considered the report of the Reference Committee on Medical Education which was adopted as a whole and recommended that particular specialties in which residents are being trained should be represented on the staff by well qualified people, whether or not they are members of "special societies and colleges or are certified in their specialty"; that it is not essential that all hospital residencies should adopt the same program, but it is essential that all hospitals participating in graduate training be able to meet fundamental essential requirements; that attendance at hospital staff meetings is not mandatory; that state medical societies be urged to use their influence with various state boards to give proportionate consideration to pediatrics as is given to other fields of medicine; that the practice of some hospitals making specialty board ratings a requirement for appointment or promotion be disapproved.

At this time Dr. Bauer announced that the Board of Trustees had extended the contract of Whitaker and Baxter for another year, stating, "We have very great hopes that we can carry on in a very greatly reduced tempo from what we have during the past year. On the other hand, we feel that it would be a great mistake to break up our organization which we have established and which has been so successful, because we don't know what may happen."

The House of Delegates heard the report of the Reference Committee on Sections and Section Work. The resolution requesting an appropriation for section delegates was referred to the Board of Trustees. The House approved recommendation that the Council on Scientific Assembly consider creation of a Section on Military Medicine and Surgery and a Section on Medicine in Industry.

The House next considered the report of the Reference Committee on Amendments to the Constitution and By-Laws and approved appointment of an Interim Committee of the House of Delegates on Amendments to the Constitution and By-Laws; setting amounts of annual dues at the annual meeting; giving the Board of Trustees specific authority with respect to remission of membership dues; allowing Associate Fellows privilege to participate in the Scientific Assembly, without the right to vote or hold office; allowing member or service fellows, active members, associate, affiliate or honorary fellows, invited guests, medical students of approved schools, and interns and residents of approved hospitals to register.

The House next heard the report of the Reference Committee on Hygiene and Public Health and approved resolutions providing earlier detection of diabetes through self-testing for sugar; and earlier detection of cancer through use of all recognized facilities for the initial diagnosis, including examination of tissues, exudates and bodily excretions.

The House approved the resolution on Medical Relations in Workmen's Compensation reported by the Reference Committee on Industrial Health, providing: that the Council on Industrial Health investigate the present status of medical relations under the Workmen's Compensation laws of the states, territories and federal government and report back to the House of Delegates in June, 1951.

The House recessed at 12 noon.

Afternoon Session

The House reconvened at 2:05 p.m. and considered the report of the Reference Committee on Legislation and Public Relations. The House approved a resolution opposing H.R. 5865, declaring "that it would place local health units in the country under substantially direct and complete control of the Surgeon General of the Public Health Service"; opposing again S. 1411 as long as Section C still remains in the bill. The House approved the committee's opinion that, as a general principle, the American Medical Association should not take a position favoring or opposing legislation which does not bear directly on medicine; approved expansion and strengthening of the Washington office; approved appointment of a committee to study the 12-Point program with the idea of making changes which may be indicated.

The House approved the report of the Committee on Training of Interns which recommended the inauguration of a 2-year rotating internship program covering the main branches of medicine, surgery, obstetrics and gynecology.

The House heard the report of the Reference Committee on Emergency Medical Service and approved a resolution urging immediate passage of Federal and state enabling legislation for a civil defense organization; a resolution urging appointment of a medical advisory committee to function at the top level of the Chairman of the National Security Resources Board.

The House next considered the report of the Reference Committee on Miscellaneous Business and approved resolutions providing better co-ordination of scheduling American Medical Association council meetings; continuation of National Education Campaign, endorsing work of the World Medical Association; declaring as ethical for members to engage in lectures, demonstrations, the preparation of pamphlets and other measures suitable for the dissemination of information designed to prevent blindness and directed to any non-medical groups.

The House then heard the report of the Committee on Veterans Affairs. The resolution to recommend more stringent rules regarding treatment of non-service-connected illness was tabled.

Dr. Bauer explained an additional change necessary in the By-Laws concerning payment of dues and Fellowship classification, which was laid over for twenty-four hours to be brought up at the next meeting. Dr. Bauer also announced that the Clinical Session will be held in Cleveland, December 5 to 8.

The House then considered the report of the Reference Committee on Insurance and Medical Service. The House approved the report which provided recommendations of expansion of medical prepayment plans for graduate nurses; recommendation for further extension of service-connected medical care for veterans through existing channels and home-town medical programs; recommendation to the Council on Medical Service that detailed procedural directions be given for action on the local level; approval of the work of the Commission on Chronic Illness.

The House recessed at 4:10 p.m.

Fourth Meeting—Thursday, June 29

Afternoon Session

The House reconvened at 1:30 p.m. and heard the report of the Reference Committee on Emergency Medical Service and approved a resolution recommending continued co-operation with the medical services of the Armed Forces and the National Security Resources Board to the end that the most effective utilization of medical personnel be achieved for the maximum protection of the nation.

The House adopted an amendment to the By-Laws providing that dues shall include subscription to *The Journal of the American Medical Association* beginning January 1, 1951.

The proposed change in the By-Laws regarding classification of fellows was referred to the Interim Committee on Amendments to the Constitution and By-Laws for study and report at the Clinical Session in Cleveland.

The House approved membership dues for 1951 at $25.00.

The House instructed the Secretary and General Manager to have the report of the Reference Committee on Reports of Board of Trustees and Secretary mimeographed and mailed to each member of the House of Delegates at the earliest possible time.

The House passed a resolution requesting the Board of Trustees to expedite adequate appropriations by the Congress to help control tuberculosis among the Indians.

The House heard the address of Rear Admiral Joel T. Boone, United States Navy.

The election of officers followed:

President-Elect—John W. Cline, M.D., San Francisco, California.

Vice President—R. B. Robins, M.D., Camden, Arkansas.

Secretary—George F. Lull, M.D., Chicago.

The House heard addresses by Dr. Cline and Dr. Robins and then elected Dr. Josiah J. Moore, Chicago, as Treasurer, and Dr. F. F. Borzell, Philadelphia, as Speaker, both succeeding themselves.

Dr. James R. Reuling, Bayside, N. Y., was elected Vice Speaker.

The House elected two new trustees: Dr. Thomas P. Murdock, Meriden, Conn., to succeed Dr. James R. Miller, Hartford, and Dr. L. W. Larson, Bismarck, N. D., to succeed Dr. John H. Fitzgibbon of Portland, Oregon.

The speaker appointed the following as members of the Interim Committee on Amendments to the Constitution and By-Laws: Drs. Joseph D. McCarthy, Omaha; Floyd S. Winslow, Rochester, N. Y.; B. E. Pickett, Sr., Carrizo Springs, Texas; Louis A. Buie, Rochester, Minn., and Stanley H. Osborn, Hartford, Conn.

Dr. Bauer announced that the annual session for 1951 will be held in Atlantic City, N. J., and that the 1952 session will be held in Chicago. The House heard the invitation of New York City, given by Dr. J. Stanley Kenney, to hold the 1953 session there. Ballots were spread.

Dr. Louis A. Buie, Rochester, Minn., was elected to succeed himself for five years as a member of the Judicial Council, Dr. J. B. Lukins, Louisville, Ky., was also elected a member.

Dr. Edgar V. Allen, Rochester, Minn.; Dr. James Stevenson, Tulsa, Okla., and Dr. Julian P. Price, Florence, S. C., were appointed as members of the Committee on Distinguished Service Awards, Dr. Allen as chairman.

Dr. Henry R. Viets, Boston, was elected to succeed himself as a member of the Council on Scientific Assembly and Dr. Russell L. Haden, Crozet, Va., was elected to succeed himself as a member of the Council on Medical Education and Hospitals.

Dr. George F. Lull, Secretary, presented the names of applicants for Associate Fellowships. Minnesota Associate Fellowships were granted to: Nellie O. N. Barsness, St. Paul; Edgar D. Brown, Paynesville; Frank D. Gray, Marshall; J. C. Hultkrans, Minneapolis; Oscar F. Mellby, Thief River Falls; F. P. Strathern, St. Peter.

The House voted, by plurality, that the annual session for 1953 be held in New York City.

Dr. James R. McVay, Kansas City, Mo., was elected by acclamation to succeed himself on the Council on Medical Service, and the ballot was spread to elect a successor to Dr. Jesse D. Hamer, Phoenix, Ariz.

Dr. Bauer introduced Dr. Pedro Nogueira, Secretary of the Cuban Medical Association, who brought greetings from his country, and Dr. José Angel Bustamante, Secretary of the Pan-American Medical Association, who also brought greetings.

The House passed a resolution of appreciation to the State of California, the San Francisco County Medical Association and the California Medical Association, and a resolution of appreciation to the city of San Francisco.

Dr. Jesse D. Hamer was elected to succeed himself as a member of the Council on Medical Service.

The House of Delegates to the American Medical Association adjourned at 3:30 p.m.

"**AMINOPHYLLIN** shares the actions and uses of other theophylline compounds, over which it has the advantage of greater solubility. It is useful as a diuretic and myocardial stimulant for the relief of pulmonary edema or paroxysmal dyspnea of congestive heart failure. . . . Aminophyllin is also useful in the control of Cheyne-Stokes respiration and for the treatment of paroxysms of bronchial asthma or status asthmaticus."

✦ Reports and Announcements ✦

AMA CLINICAL SESSION

The fourth clinical session of the AMA, designed primarily for the general practitioner, will be held in Cleveland, December 5 through 8. The scientific sessions and the scientific exhibits will be presented in the Cleveland Municipal Auditorium. The House of Delegates will meet at the Statler Hotel.

Outstanding clinical teachers will appear on the program. Clinical sessions will be limited to an attendance of 100 physicians. Obstetric, pediatric and geriatric problems, traumatic surgery, cancer and diabetes will be among the subjects of interest to the general practitioner which will be discussed. This midyear meeting aids the general practitioner in keeping abreast of medical progress.

AMERICAN COLLEGE OF CHEST PHYSICIANS

The fifth annual Postgraduate Course in Diseases of the Chest, sponsored by the Council on Postgraduate Medical Education and the Illinois State Chapter of the American College of Chest Physicians, with cooperation of the members of the staffs of the medical schools and hospitals of Chicago, will be held at the St. Clair Hotel, Chicago, October 16 through 20.

Addresses on medical and surgical phases of chest diseases will be given at the morning and afternoon sessions, with round-table discussions each noon. The evening of October 19 will be given over to a banquet, to be followed by a meeting of the Illinois chapter of the College.

The number of registrants for the course is limited. Applications, with a remittance of $50, should be sent to the American College of Chest Physicians, 500 North Dearborn Street, Chicago 10, Illinois.

AMERICAN COLLEGE OF PHYSICIANS

The Midwest Regional Meeting of the American College of Physicians will be held at the Memorial Union Theatre on the campus of the University of Wisconsin in Madison, Wisconsin, Saturday, November 18, 1950. Physicians of Minnesota, Illinois, Indiana, Iowa, Ohio, Michigan and Wisconsin, whether members of the College or not, are urged to attend.

Registration at 8 A.M. will be followed by fifteen-minute papers on a wide variety of medical subjects, the afternoon session terminating at 5 P.M. A social hour follows at 5:30 P.M. In addition, a scientific exhibit will be presented in the foyer of the Memorial Union Theatre.

For further information, address Dr. H. M. Coon, 1300 University Avenue, Madison 6, Wisconsin.

AMERICAN COLLEGE OF SURGEONS

A sectional meeting of the American College of Surgeons will be held in St. Louis on January 22 and 23. All physicians who wish to attend are invited. A registration fee of $5 for nonmembers can be expected. Minnesota is included among the midwestern states in the section of the country for which this meeting has been arranged.

Headquarters will be at Hotel Statler, and an extra day of operative clinics will be conducted in addition to the two days of addresses. Further information can be obtained from Dr. Barrett Brown, 400 Metropolitan Building, Grand Avenue and Olive Street, St. Louis 3, Missouri.

NATIONAL GASTROENTEROLOGICAL ASSOCIATION

The National Gastroenterological Association will hold its fifteenth annual convention and scientific sessions at the Hotel Statler in New York City, October 9 through 11.

At the annual banquet of the Association, to be held at the Hotel Statler on October 10, the winner of the National Gastroenterological Association 1950 Prize Award Contest for the best unpublished contribution on gastroenterology and allied subjects, will receive the prize of $100 and a certificate of merit.

Immediately following the convention, the Association is conducting a course in postgraduate gastroenterology at the Hotel Statler in New York City on October 12 through 14.

Further information concerning the program and details of the course may be obtained by writing to the Secretary, National Gastroenterological Association, 1819 Broadway, New York 23, N. Y.

VAN METER PRIZE AWARD

The American Goiter Association again offers the Van Meter Prize Award of $300 and two honorable mentions for the best essays submitted concerning original work on problems related to the thyroid gland. The award will be made at the annual meeting of the Association which will be held in Columbus, Ohio, May 24, 25 and 26, 1951, providing essays of sufficient merit are presented in competition.

The competing essays may cover either clinical or research investigations, should not exceed three thousand words in length, must be presented in English, and a typewritten double spaced copy in duplicate sent to the Corresponding Secretary, Dr. George C. Shivers, 100 East Saint Vrain Street, Colorado Springs, Colorado, not later than March 1, 1951. The committee who will review the manuscripts is composed of men well qualified to judge the merits of the competing essays.

A place will be reserved on the program of the annual meeting for presentation of the Prize Award Essay by the author, if it is possible for him to attend. The essay will be published in the annual Proceedings of the Association.

Now Available . . . .

Complete, modern facilities of the Glenwood Hills Hospitals; co-ordinated to give an accurate diagnosis and proper treatment to the neuropsychiatric patient.

These unique facilities include:

- The outstanding staff of neurologists and psychiatrists in the United States
- The new Electroencephalograph
- The new Electrocardiograph
- An ultra-modern laboratory
- A completely equipped x-ray room
- Occupational therapy and Hydrotherapy
- A new physical education department
- Nurses specially trained in our own neuropsychiatric training school

QUOTA FILLED —

For the September class for the School of Neuropsychiatric Nursing. Registration is now open for the January class.

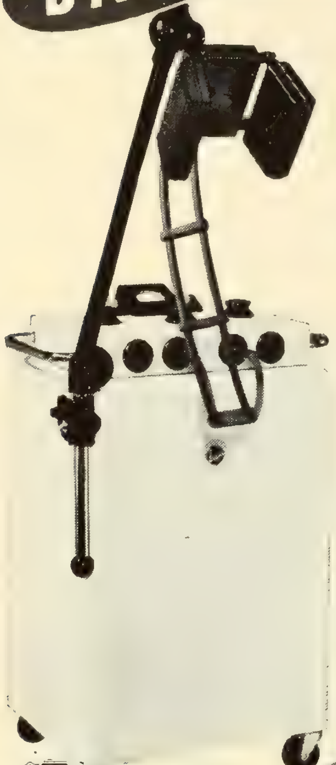
BIRTCHER
Crystal
BANDMASTER

SHORT WAVE DIATHERM with the TRIPLE INDUCTION DRUM



The Bandmaster has been approved or accepted by the following:

✓ A.M.A. Council on Physical Medicine
✓ Federal Communications Commission
✓ Underwriters' Laboratory
✓ Also the Canadian Department of Transport and Canadian Standards Association

The Bandmaster Diatherm with the Triple Drum provides better diathermy and affords application of the large area technic which is being widely recognized over other methods of producing heat in the tissues.

Considerable total energy may be introduced into the deeper tissues without excessive heating of outer surfaces. Crystal control assures frequency stability for life of the unit.

Reprint of diathermy technics mailed free on request. Write "Bandmaster Booklet" on your prescription blank or clip this advertisement to your letterhead and mail to:

MINNESOTA PUBLIC HEALTH CONFERENCE

Physicians and health officers of Minnesota municipalities will meet on September 25 and 26 in the Hotel Nicollet in Minneapolis to discuss general sanitary problems of municipalities. This meeting is being held in conjunction with the fourth annual meeting of the Minnesota Public Health Conference, an organization with a membership of over 600 lay and professional health workers in Minnesota.

Authorities on sanitary problems will join with the health officers and physicians in discussions of municipal solutions of waste disposal, rodent control and other problems. The conference is also featuring a second day full program of interest to physicians. Mary Switzer of the Federal Security Agency will report on the activities of the World Health Organization. A general afternoon session features a discussion of health problems in industry, the use of mass media to get a message across to people, and techniques used in social welfare to win public support of the programs. The banquet session of the program features an address by Dr. William Sheppard of the Metropolitan Life Insurance Company, who is president elect of the American Public Health Association.

All physicians and health officers in Minnesota are invited to attend the two-day program which brings together all health interests in Minnesota.

CONTINUATION COURSES

Cortisone and ACTH.—The University of Minnesota announces a continuation course for physicians on cortisone and ACTH to be presented at the Center for Continuation Study on October 4.

Subject matter for the course will include pituitary adrenal interrelationships, the alarm reaction, and tests of adrenal cortical function. The use of cortisone and ACTH in allergic states, rheumatic fever, rheumatoid disease, and eye disorders will highlight the therapeutic section of the course.

Faculty for the course will include members of the staffs of the Mayo Clinic and the University of Minnesota Medical School.

Medical Technologists.—The University of Minnesota announces a continuation course for medical technologists on October 10 and 11. The course will be presented at the Center for Continuation Study and will be devoted to problems in clinical chemistry. Among the subjects to be discussed will be the reliability and validity of methods in clinical chemistry, the use of the flame photometer and spectrophotometer, technique and interpretations of liver function tests, plasma protein determination, and serum cholesterol determination, techniques, and interpretation. The visiting faculty member for the course will be Dr. Olaf Michelsen, biochemist of the Division of Chronic Disease of the United States Public Health Service. Members of the faculty of the University of Minnesota will complete the staff for the course. Graduates in technology are eligible to attend.

A HOMELIKE HAVEN WHERE ALCOHOLICS ACHIEVE INSPIRATION FOR RECOVERY

200 acres on the shores of beautiful Lake Chisago where gracious living, homelike atmosphere and understanding companionship contribute to successful rehabilitation.

HAZELDEN FOUNDATION

The constructive thinking of a group of Twin Cities men seeking a new approach to the problem of alcoholism resulted in the organization of the Hazelden Foundation. Some of the founders are themselves men who have recovered from alcoholism through the proved program of Alcoholics Anonymous. Their true understanding of the problem has resulted in the treatment procedures used at the Hazelden Foundation.

POSTGRADUATE SEMINARS

Two preliminary planning meetings for the conduct of professional postgraduate seminars were held recently. On July 26 members of the different professions, as well as interested lay persons, met at the St. Francis Hospital, Crookston, to discuss plans for the forthcoming seminar.

Dr. R. O. Sather of Crookston, secretary of the Red River Valley Medical Society, and Dr. O. K. Behr, also of Crookston, represented the local medical profession.

Dr. R. E. Siman and Dr. H. F. Jung were there representing the dental group. Miss Margaret Sherman, Miss Ruby Gregerson, Miss Blanche Ingvalson, Mrs. Eva Brown, and Miss Ida Twedten were from the nursing profession.

Dr. George N. Aagaard, director of postgraduate medical education at the University of Minnesota; Mr. Thomas A. Morrow, executive secretary of the Minnesota Heart Association; Dr. William A. Jordan, director, Division of Dental Health, and Mr. E. W. Eagle, pharmacist in Crookston, were also present. Sister Mary Charitas, as administrator, represented St. Francis Hospital.

The Crookston seminar, scheduled for September 13 to November 1, is a joint undertaking of the University of Minnesota Medical School, the Minnesota State Medical Association, and the Minnesota Department of Health. It is one of six planned for Minnesota communities during the 1950-51 season.

On July 27 a similar planning meeting for a seminar to be held at Virginia was conducted at the Virginia Municipal Hospital. This seminar, with the same sponsors, will start September 21 and end November 9.

Dr. J. A. Malmstrom, president, Range Unit of the St. Louis County Medical Society; Dr. E. N. Peterson, chief of staff, Virginia Municipal Hospital; Dr. R. P. Pearsall, city health officer, Virginia, Minnesota; and Dr. N. M. Strandfjord represented the physicians. Dr. L. C. Krause represented the dental profession.

Mrs. Inez Christen, president, Tenth District Minnesota Nurses Association; Mrs. Madeline Takala, St. Louis County public health nurse, Virginia; Miss Esther Hakko, St. Louis County public health nurse, Virginia; and Mrs. Barbara Rodorigo, St. Louis County P.H.N., Virginia, Minnesota, were present for the nursing group.

Dr. George N. Aagaard, Mr. Thomas A. Morrow, Dr. William A. Jordan, and Mr. Charles C. Crosby, pharmacist from Virginia, were present. Mr. John Alexon, superintendent, represented the Virginia Municipal Hospital.

The other seminar areas, together with approximate attendance dates in 1951 are:

Moorhead	January 3 to February 21
Willmar	January 11 to March 1
Worthington	March 6 to April 24
Albert Lea	March 14 to May 2

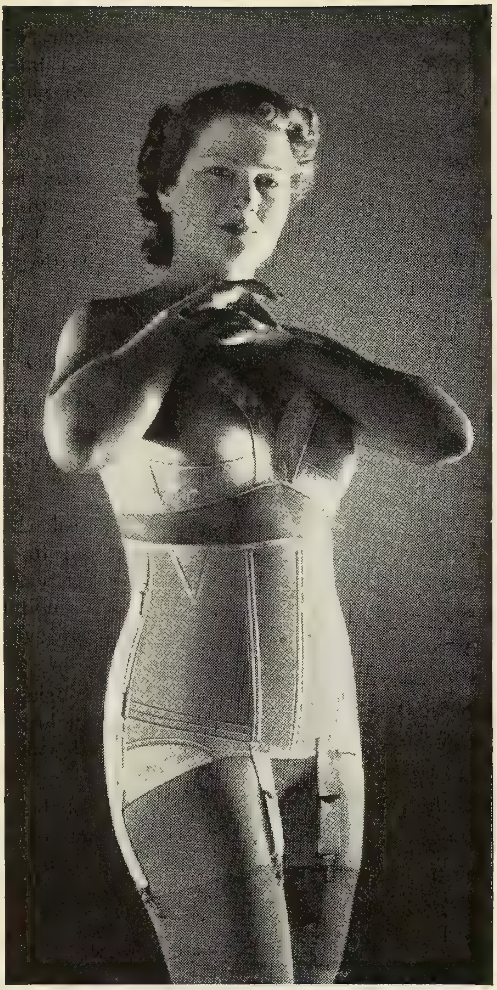
CAMP

for POSTOPERATIVE and POSTPARTUM NEEDS



Basic design and the unique system of adjustment make a large variety of Camp Scientific Supports especially useful as postoperative aids. Surgeons and physicians often prescribe them as assurance garments and consider them essential after operation upon obese persons, after repair of large herniae, or when wounds are draining or suppurating. A Camp Scientific Support is especially useful in the postoperative patient with undue relaxation of the abdominal wall. Obstetricians have long prescribed Camp Postoperative Supports for postpartum use. Physicians and surgeons may rely on the Camp-trained fitter for precise execution of all instructions.

If you do not have a copy of the Camp "Reference Book for Physicians and Surgeons", it will be sent on request.

Authorized Service

POSTGRADUATE SEMINARS

(Continued from Page 938)

The seven courses held throughout the state in 1949-50 were extremely well received, and professional attendance and interest was excellent.

Heart disease, cancer control and mental health will be the subjects of this year's programs. Latest information on the diagnosis, treatment, and management of diseases in these three fields will be presented by leading medical lecturers from the University of Minnesota Medical School. Professional films and literature will in some instances be used to augment the speakers.

Each seminar, as last year, will consist of eight consecutive weekly meetings, with each session about two hours long. Ordinarily two speakers, each on a different subject matter, will appear.

There is no charge for this series of lectures unless local physicians voluntarily assess themselves $2 each to obtain a certificate of attendance.

County medical societies are actively co-operating in the organization and conduct of these significant medical education events.

Coinciding with these medical seminars, dentists and nurses of the area will hold eight sessions of their own, patterned generally after the physician's courses, with subject matter tailored to their specific interests. The University of Minnesota Schools of Dentistry and Nursing, the Minnesota State Dental Association, the Minnesota State Nurses Association, and local dental and nursing groups sponsor the seminars.

Other co-sponsors of the seminars are the Minnesota Division of the American Cancer Society, the Minnesota Heart Association, and the Minnesota Mental Hygiene Society.

LYON-LINCOLN MEDICAL SOCIETY

The forty-second semi-annual clinic course of the Lyon-Lincoln County Medical Society began on September 5 and will end on October 10. All meetings are held at the New Atlantic Hotel in Marshall and begin with dinner at 6:30 p.m. The program for the course is as follows:

Sept. 5—"Diagnosis and Treatment of Head Injuries"—Dr. Wallace P. Ritchie, Saint Paul.

Sept. 12—"Some Practical Aids in Prolonged Labor"—Dr. E. A. Banner, Rochester.

Sept. 19—"Psychosomatic Medicine"—Dr. Gordon Kamman, Saint Paul.

Sept. 26—"Emergency Surgery of the Abdomen"—Dr. O. H. Beahrs, Rochester.

Oct. 3—"Cardiovascular Renal Emergencies"—Dr. T. W. Parkin, Rochester.

Oct. 10.—"Rheumatic Fever in Children with Special Emphasis on the Differential Diagnosis"—Dr. Albert Stoesser, Minneapolis.

In Memoriam

FRANK J. BRABEC

Dr. Frank J. Brabec, a practitioner at Perham, Minnesota, since 1893, died July 29, 1950, at the age of eighty-one.

Dr. Brabec was born at Watertown, Minnesota, January 31, 1869. He received his medical degree from the University of Minnesota in 1893. After graduation, he took his internship at Asbury Hospital, Minneapolis, and St. Joseph's Hospital, Saint Paul. On his return trip from Butte, Montana, where he had accompanied Dr. Charles Wheaton of Saint Paul to assist in an operation on Senator Carter of Montana, the train was delayed at Perham and Dr. Brabec was so impressed with the surrounding country that he decided to practice there.

Dr. Brabec was instrumental in persuading the Franciscan Sisters to establish a hospital at Perham. He also donated a farm to the village for the benefit of a library addition.

Dr. Brabec is survived by his wife; two sons, Dr. Leonard Brabec, an educator in New York, a child by his first wife who died a number of years ago, and Dr. Paul Brabec of Forsythe, Montana, and a daughter, Katheryn, of Saint Paul.

He was a former member of the Park Region Medical Society, the Minnesota State Medical Association and the American Medical Association.

KENNETH G. WILSON

Dr. Kenneth G. Wilson, formerly of Minneapolis, died at Laguna Beach, California, June 19, 1950, at the age of thirty-four.

Dr. Wilson was born in Minneapolis, August 27, 1915. He attended Washburn High School in Minneapolis and received the degree of B.S. from the University of Minnesota in 1938 and an M.D. in 1940. After interning at St. Luke's Hospital in San Francisco, he took postgraduate work at the Mayo Foundation specializing in aeronautical medicine.

During World War II, he was a flight surgeon at General Motors bomber plant, Cleveland, and at Consolidated Vultee Corporation, San Diego, California. He was a member of Psi Upsilon and Nu Sigma Nu fraternities.

Dr. Wilson is survived by his parents, Mr. and Mrs. Alfred E. Wilson of Minneapolis, a brother, John R., of San Francisco and a sister, Mrs. Cora J. Compton, of Minneapolis.

My duty (men have duty; and, if I would be a man,
Then I must bow to duty) is to do the best I can,
In ev'ry way, and ev'ry day, till I grow big enough
To realize the best of men are diamonds in the rough.
Time has a way of telling man its truths before he dies;
He profits most who serves the best. My job—there it
lies.

The annual Leo G. Rigler lecture in radiology will be given at the University of Minnesota on November 2 by **Dr. Knut Lindblom** of the Karolinska Institute in Stockholm, Sweden. Dr. Lindblom will speak on "Backache" at 8:15 p.m. in the ampitheater of the University Medical Sciences Building. The lecture will be given in connection with a course in neuroradiology held October 30 through November 3 at the University Center for Continuation Study.

* * *

Dr. L. E. Steiner, Albert Lea, was elected secretary of the Freeborn County Medical Society at the June 1 meeting of the organization. He succeeds Dr. E. S. Palmerton, who is taking a residency at the University Hospitals.

* * *

Dr. William S. Chalgren opened an office in Mankato on July 1 for the practice of neurology and psychiatry. A graduate of the University of Minnesota Medical School in 1943, Dr. Chalgren served his internship and a residency in neuropsychiatry at the University Hospitals. After a period of service in the Army, he returned to the University department of neuropsychiatry, and in 1949 he received a Ph.D. degree in neurology and was certified by the American Board of Psychiatry and Neurology. Formerly an assistant professor of neuropsychiatry at the University, he is now on the staff as a clinical assistant professor. He is also consultant in neurology at the St. Cloud Veterans Hospital and consultant in neuropsychiatry at the Nicollet Clinic, Minneapolis.

* * *

Dr. and Mrs. John Briggs, Saint Paul, left on August 21 to attend the International Congress of Cardiology, scheduled to open in Paris September 3. Dr. Briggs will address the International Congress of Chest Physicians at the Foralani Institute in Rome on September 20.

* * *

Dr. Burton C. Ostling began the practice of medicine in Kerkhoven on August 1. A graduate of the University of Michigan, Dr. Ostling has practiced for a year at Hastings.

* * *

Announcement of the appointment of **Dr. Robert B. May** as clinical director and assistant superintendent of the Fergus Falls State Hospital was made during the middle of July. At the time of the appointment Dr. May was serving in a similar capacity at the Willmar State Hospital.

Dr. May's previous experience includes work at the Hastings State Hospital in Nebraska and at the Greystone Park Hospital in Trenton, N. J. He has also been clinical director in one of the Maryland state hospitals and superintendent of the Eastern Shore State Hospital in Maryland.

* * *

After almost a year without the services of a local physician, Wanamingo acquired a resident physician late in July when **Dr. J. T. Boswell** opened offices there for the practice of medicine. A native of Oklahoma, Dr. Boswell served his internship at the U. S. Naval Hospital at Great Lakes, Illinois.

* * *

Dr. Paul Wendt, formerly of Sauk Rapids, became associated with the Johnson Clinic in Thief River Falls early in July. A graduate of the University of Minnesota Medical School, Dr. Wendt recently completed his internship at the Milwaukee County Hospital, Wisconsin.

* * *

Dr. Virgil J. P. Lundquist has opened offices at 829 Medical Arts Building, Minneapolis. He was recently affiliated with the University Hospitals and the Minneapolis Veterans Hospital.

* * *

Dr. J. A. Malerich and **Dr. William T. Miller** have moved into new offices at 914 South Robert Street, West Saint Paul.

* * *

Dr. C. L. Roholt left Waverly on July 21 to take a postgraduate course in general surgery in Chicago.

* * *

It was announced on July 20 that **Dr. Francis J. Braceland,** Rochester, had been appointed chairman of the governor's advisory council on mental health. Dr. Braceland, chief of the psychiatric section of the Mayo Clinic, succeeds Dr. Alexander G. Dumas, Minneapolis, who resigned as chairman because of ill health. Dr. Dumas retains a seat on the council, however.

Dr. Braceland has been a member of the council since 1947. In 1949 he was named co-consultant to the Division of Public Institutions in the development of Minnesota's mental health program. He has been head of the section on psychiatry and the department of neurology and psychiatry at the Mayo Clinic since April, 1947.

* * *

Dr. F. C. Dolder was presented with a lifetime membership in the Eyota Businessmen's Association at a meeting of the group in Eyota on July 13. Dr. Dolder was honored for his enthusiasm and activity in the association's projects during the past years.

* * *

Dr. David R. Philip has become associated in practice with Dr. L. H. Hoyer in the Windom Clinic. Dr. Philip has had postgraduate training in obstetrics and pediatrics. He is a former resident of Mankato.

* * *

It was announced on July 14 that **Dr. and Mrs. Louis H. Stahn** had returned from Spokane, Washington, and that Dr. Stahn planned to open an office for the practice of medicine in Minneapolis.

* * *

Two new physicians have joined the staff of the Itasca Clinic. They are **Dr. Larry E. Karges,** lo-

cated at Grand Rapids, and **Dr. Roy R. Juntunen,** who is with the clinic at Nashwauk. Both are graduates of the University of Minnesota Medical School. Dr. Karges interned at Ancker Hospital, Saint Paul, and Dr. Juntunen served his internship at St. Mary's Hospital, Duluth.

* * *

Dr. O. L. McHaffie, Duluth, has been named St. Louis County Medical Society representative to the Duluth Rehabilitation Center board of directors.

* * *

Dr. F. Donald Bucher opened offices for the practice of medicine in Starbuck on July 24. A graduate of the University of Nebraska, he served his internship at St. Joseph Hospital, Sioux City, Iowa. He has spent two years in service with the Navy.

* * *

Dr. W. W. Will, Bertha, is one of several physicians to be heard on a special radio broadcast this fall sponsored by the University of Minnesota as part of its centennial celebration. On the broadcast, which has been tape-recorded, Dr. Will is interviewed as he describes his experiences as a "country doctor." He is also heard in a typical office interview with a person imitating a patient. The title of the broadcast is "Minnesota Mid-Century," and the interviews with physicians are part of the medicine and health portion of the program.

* * *

Dr. Anthony L. Ourada, who recently completed a residency in surgery at Swedish Hospital, Minneapolis, began medical practice in Waseca on July 17. A graduate of the University of Minnesota Medical School in 1946, Dr. Ourada served his internship at St. Elizabeth's Hospital in Youngstown, Ohio. He then spent sixteen months in the Army in Germany.

* * *

Dr. A. M. Ridgway, Annandale, said to be the oldest practicing physician in Minnesota, observed his sixtieth year of practice on July 15.

* * *

Dr. Lewis Thomas, former professor of pediatrics and medicine at Tulane University, has been appointed to the American Legion memorial research professorship in rheumatic fever and heart disease at the University of Minnesota Medical School. The professorship was established through funds provided by the Minnesota American Legion and its auxiliary. Dr. Thomas, a graduate of Harvard University in 1937, will study causes and treatment of rheumatic fever and heart disease and will direct special research teams.

* * *

Dr. and Mrs. R. V. Williams left Rushford on July 25 for a trip to Norway. They planned to spend two months visiting various points in Norway before returning to Rushford.

* * *

Two physicians specializing in the practice of internal medicine opened a new medical office in Mankato on July 27. **Dr. Robert H. Conley** and **Dr. Benjamin R. Guers,** who had been in Mankato since June, announced that their new offices had been completely remodeled and equipped.

Both physicians are graduates of the University of Minnesota Medical School and both recently completed three years of postgraduate work at the University Hospitals and Minneapolis Veterans Hospital. Dr. Conley served his internship at Rochester General Hospital, Rochester, New York, and then spent three years in the Navy. Dr. Guers interned at Ancker Hospital, Saint Paul, and served in the Army for three years.

* * *

Dr. Bernard S. Nauth opened offices for the practice of medicine in Bemidji on July 31. A graduate of the University of Minnesota Medical School in 1941, Dr. Nauth served in the Army for two and one-half years. He spent the past five years as a general practitioner in the Winona Clinic.

* * *

Dr. John R. Zell, a native of Mankato, has accepted an appointment for a three-year residency in neuropsychiatry at the United States Veterans Hospital at Coatsville, Pennsylvania. Dr. Zell recently completed his internship at the U. S. Naval Hospital in Philadelphia.

* * *

Dr. Arthur H. Borgerson, Long Praire, has been invited to speak at a meeting of the American Association of Blood Banks in Chicago October 12 through 14. He has been asked to describe the methods used in establishing a blood bank in Long Prarie, which was the first community in Minnesota, outside of the metropolitan centers, to set up such a blood bank system.

* * *

On July 24 the residents of Northome could again obtain the services of a local physician after being without them for almost two years. On that day **Dr. Gordon Franklin** opened offices for the practice of medicine in Northome.

A native of Vernon Center, Dr. Franklin is a graduate of the College of Medical Evangelists. He interned at the Glendale Sanatorium and Hospital in Los Angeles and took additional training at St. Luke's Hospital, Saint Paul.

During the past two years Dr. Roger MacDonald of Littlefork served the Northome community two days each week.

* * *

Dr. Yngve Hakanson, after a year and one-half of study in cell research and biochemistry at the Karolinska Institute in Stockholm, Sweden, joined the department of obstetrics and gynecology at the University of Minnesota on August 1.

* * *

Dr. B. O. Mork, formerly of Worthington, has been appointed medical director of one of the Los Angeles eight public health districts. He will combine his new activities with his work on the faculty of the University of California at Los Angeles.

* * *

Mrs. Horace Newhart, wife of the late Dr. Newhart, died in Minneapolis on August 14. Long active in

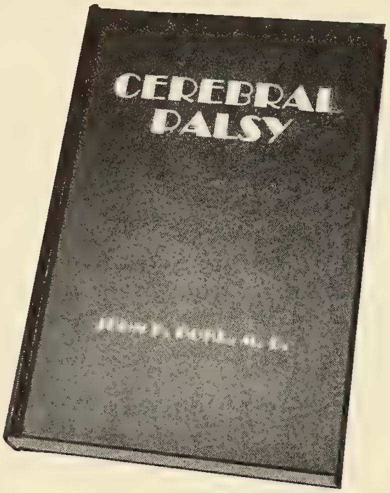
**The First Complete
and Authoritative
Medical Text on the
Diagnosis and
Treatment of**



"Cerebral Palsy"

by John F. Pohl, M.D.

Cerebral palsy is **not** a hopeless disorder. Careful application of proper training methods can often enable the cerebral palsied child to become completely independent and eventually self-supporting.

In his new book "Cerebral Palsy" Dr. John F. Pohl presents detailed descriptions of tested therapeutic techniques—original methods that were developed during twelve years of research with many actual cases of cerebral palsy. All phases of therapy are covered—with major emphasis on relaxation, neuromuscular training, developmental patterns, walking, occupational therapy, and speech.

More than 130 photographic illustrations and drawings supplement the eleven descriptive chapters and vividly demonstrate each step to be taken in the treatment of all types of cerebral palsy.

• • •

Dr. John F. Pohl is a Diplomate of the American Board of Orthopedic Surgery and is orthopedic surgeon at the Michael Dowling School for Crippled Children. He is also the author of "The Kenny Concept of Infantile Paralysis and Its Treatment," thousands of copies of which have been sold throughout the world.

church and women's groups, she was also president of the Minneapolis Society for the Hard of Hearing. She had been a director of Northwestern Hospital, Minneapolis, for more than forty years.

* * *

On August 7 the Rochester city council approved a health department resolution hiring **Dr. George Williams,** Saint Paul, as psychiatrist with the department's counseling clinic. Dr. Williams, affiliated at present with the University of Minnesota, will replace Dr. Robert Fawcett as the clinic psychiatrist on January 1.

* * *

Dr. Wallace R. Anderson joined the staff of the Austin Clinic on August 1. A graduate of the University of Minnesota Medical School, he interned at Minneapolis General Hospital, following which he took two years of postgraduate training in pediatrics. His practice at Austin will be limited to this specialty.

* * *

Dr. and Mrs. Rudolph B. Skogerboe and family returned home to Karlstad on July 25 from a three-week vacation, two weeks of which were spent in New York and one at Lake Andrusia.

* * *

Dr. Nelson J. Bradley has been appointed superintendent of the Willmar State Hospital, succeeding Dr. Stanley B. Lindley, who had resigned to join the staff of the Veterans Administration Hospital in Knoxville, Iowa. At the time of his appointment, Dr. Bradley was acting superintendent of the Hastings State Hospital, a position he had held since the former superintendent, Dr. Ralph Rossen, was appointed state mental health commissioner last January.

A graduate of the University of Alberta, Dr. Bradley has taken postgraduate work at the University of Minnesota. He joined the Hastings State Hospital staff in 1948.

* * *

Dr. Alphonse Cyr, Barnesville, was appointed Clay County health officer at a commissioner's meeting in Moorhead early in July. Dr. Cyr replaces Dr. Olga H. Johnson, Moorhead, who resigned from the office.

* * *

Dr. Cherry B. Cedarleaf has become associated in practice with Dr. L. H. Rutledge and Dr. C. W. Moberg in Detroit Lakes. A graduate of the University of Minnesota Medical School, Dr. Cedarleaf interned at the Waterbury Hospital, Waterbury, Connecticut, and then spent two years in resident graduate work at Northwestern Hospital, Minneapolis.

* * *

Dr. George W. Heine became associated in practice with Dr. G. M. A. Fortier at the Little Falls Clinic on August 1. A graduate of the University of Minnesota Medical School in 1948, Dr. Heine interned at St. Luke's Hospital, Duluth, and then spent one year at the Oakland Naval Hospital.

* * *

Dr. and Mrs. Edmund Miller and their son, Robert, returned home to Anoka in July from a trip to the West Coast. While in California, Dr. Miller presented a paper on the care of tuberculosis patients in institutions at a meeting of the American College of Chest Physicians in San Francisco on June 25.

* * *

Dr. L. E. Gallett, formerly of Pulaski, Wisconsin, has opened offices for the general practice of medicine at 2131 West Old Shakopee Road, Bloomington (Minneapolis). A graduate of the University of Wisconsin Medical School, Dr. Gallett practiced at Pulaski for eight years. He recently completed a year of postgraduate study in allergy at the Cook County Graduate School of Medicine.

* * *

Three Rochester physicians will present papers at the eighty-fifth annual session of the Michigan State Medical Society in Detroit September 20 through 22. Dr. Louis A. Brunsting will speak on "The Present Status of the Syphilis Problem." Dr. John R. McDonald will discuss "The Clinical Importance of Early Cancer," and Dr. James T. Priestley's subject will be "Surgical Lesions of the Stomach."

* * *

Dr. David Hoehn and his wife, **Dr. Bernice Andrews,** have replaced Dr. E. J. Schmitz in Holdingford. Dr. Schmitz gave up his practice to become a fellow in surgery at the University of Washington at Seattle. Graduates of the University of California in 1937, Dr. Hoehn and Dr. Andrews have practiced for nine years in the interior of Alaska, for two years in Tennessee, and for one year in North Dakota.

* * *

Goodhue acquired a new physician early in July when **Dr. James W. Halvorson** opened offices there for the practice of medicine. A graduate of the University of Minnesota Medical School in 1948, Dr. Halvorson served his internship at St. Mary's Hospital in Winona. He then spent one year at the U. S. Naval Hospital at Great Lakes, Illinois.

* * *

Dr. Hendrik De Kruif, formerly of Minneapolis, has moved to Fergus Falls and has become associated with the Fergus Falls Clinic.

* * *

Dr. Marshall J. Melius, formerly of Saint Paul, joined the Henry Clinic in Milaca on August 7. A graduate of the University of Minnesota Medical School, Dr. Melius served his internship at the Milwaukee County Hospital, Wisconsin. He recently completed some postgraduate training at St. Joseph's Hospital, Saint Paul.

* * *

The first meeting of the **Minnesota Clinic Managers** was held at the Androy Hotel in Hibbing on July 28 and 29. The organization consists of the managers of medical clinics in the state.

* * *

Dr. F. R. Ritzinger has become associated in practice with the Rose and Doman Clinic in Lakefield. A graduate of the University of Illinois Medical School, Dr. Ritzinger served his internship at Ancker Hospital, Saint Paul. He has completed a one-year surgical residency at Miller Hospital, Saint Paul.

"No, it didn't take me long to include MUNICIPAL BONDS in my savings program once I appreciated the security and tax-exempt features."

* * * *

Municipalities borrow money for capital improvements by the issuance of bonds. These bonds usually carry semiannual interest coupons which the investor merely deposits in his bank account, as they mature, to collect his interest. This interest is not subject to present Federal Income Taxes.

We are merchants of municipal bonds. We buy an issue of bonds from a municipality and, in turn, offer them to our customers in amounts of $1,000 each. We prepare a descriptive analysis of the bond issue, usually referred to as a circular, which outlines the amount of bonds involved, the purpose of the issue, the security, the background of the community, the resale price and the return or yield available to the investor.

We shall be pleased to send you information and descriptive circulars pertaining to municipal bonds that we have currently available for sale.

It was announced late in July that **Dr. John Reitmann** had left his position at the Hastings State Hospital to become supervisor and chief medical officer at the Sandstone State Hospital.

* * *

Dr. Anthony C. Gholz, a former resident of Worthington, has announced the opening of offices in association with Dr. William D. Cleland, Jr., in Port Huron, Michigan. Dr. Gholz is limiting his practice to pediatrics.

A graduate of the University of Minnesota Medical School, Dr. Gholz recently completed a residency at the Children's Hospital, Detroit, Michigan.

* * *

The Clarkfield Clinic announced late in July that **Dr. Curtis M. Johnson**, of Jackson, would join its staff about September 1.

The National Committee for a Free Europe, Inc., is an organization of public-spirited American citizens who operate Radio Free Europe as an independent counterpart of the government-operated Voice of America. Unhampered by government control, Radio Free Europe broadcasts anti-Communist programs from a short-wave transmitter beamed from western Germany to behind the Iron Curtain. The freedom station carries the voices and messages of exiled leaders back to the satellite countries from which they escaped.

The National Committee for a Free Europe is sponsoring a Crusade for Freedom, to be undertaken this fall to enroll Americans on Freedom Scrolls, which will be permanently enshrined in the base of a ten-ton Freedom Bell to be hung in Berlin next October.

TEACHING FACULTY—ATTENDING STAFF OF COOK COUNTY HOSPITAL
Address: REGISTRAR, 427 South Honore Street
Chicago 12, Illinois

The Mesaba Clinic staff was increased in July with the addition of **Dr. Wesley Tomhave,** who had just completed his internship at Minneapolis General Hospital. A graduate of the University of Minnesota in 1942, Dr. Tomhave served in the Navy for two and one-half years before returning to Minnesota to study medicine. He received his bachelor of medicine degree from the University Medical School in 1949.

* * *

Dr. Hans Johnson was re-elected president of the Kerkhoven school board at the annual reorganization meeting on July 5. Dr. Johnson has held the office for many years.

* * *

Physicians from five states announced on August 5 plans for a "mutual assistance disaster program" for exchange of **whole blood and plasma** in case of an atomic bombing. Meeting in Minneapolis, physicians from Minnesota, North and South Dakota, Iowa and Wisconsin emphasized the need for decentralization of blood collection so that if one center were destroyed by bombs supplies would be available elsewhere. A blood procurement and planning committee was organized to work on the problem.

* * *

In Mankato, **Dr. Roger G. Hassett** has been occupying temporary quarters while work is progressing on his new medical center building. The project involves remodeling the present structure and constructing an 87-foot two-story addition. When completed, the center will contain offices for physicians, dentists and attorneys, as well as space for a commercial firm.

* * *

It was announced on August 3 that two new physicians were moving to Pelican Rapids. **Dr. Lawrence Pearson** planned to arrive on September 1 to be associated in practice with Dr. H. A. Korda in the Pelican Valley Clinic. Dr. Pearson, who was graduated from the University of Minnesota Medical School and interned at Miller Hospital, Saint Paul, has practiced medicine at Warroad for the past nine years.

Dr. H. K. Helseth, of Mott, North Dakota, and formerly of Fergus Falls, was also planning to move to Pelican Rapids as soon as suitable office space could be found.

* * *

At a meeting of the Exchange Club in Winona on July 18, **Dr. R. H. Wilson** discussed the operational problems of the Winona General Hospital. He stated that hospital rates in Winona were high, not because of inefficient management or because somebody was trying to make a lot of money, but because of poor local patronage, inefficiency of the present physical plant, and lack of subsidization of any type. He suggested, as a solution, acquainting the public with the facts, constructing a new hospital, and converting the present structure to a convalescent and chronic disease home.

* * *

Dr. Edwin J. Simons, prominent practitioner in Swanville for more than twenty-five years, has sold his practice to Dr. Edwin G. Knight, his associate for the past eight years, and has moved to Edina (Minneapolis).

An Observation on the Accuracy of Digitalis Doses

Withering made this penetrating observation in his classic monograph on digitalis: "The more I saw of the great powers of this plant, the more it seemed necessary to bring the doses of it to the greatest possible accuracy."[1]

To achieve the greatest accuracy in dosage and at the same time to preserve the full activity of the leaf, the total cardioactive principles must be isolated from the plant in pure crystalline form so that doses can be based on the actual weight of the active constituents. This is, in fact, the method by which Digilanid® is made.

Digilanid contains all the *initial* glycosides from Digitalis lanata in crystalline form. It thus truly represents "the great powers of the plant" and brings "the doses of it to the greatest possible accuracy".

Clinical investigation has proved that Digilanid is "an effective cardioactive preparation, which has the advantages of purity, stability and accuracy as to dosage and therapeutic effect."[2]

Average dose for initiating treatment: 2 to 4 tablets of Digilanid daily until the desired therapeutic level is reached.
Average maintenance dose: 1 tablet daily.
Also available: Drops, Ampuls and Suppositories.

1. *Withering, W.:* An account of the Foxglove, London, 1785.
2. *Rimmerman, A. B.:* Digilanid and the Therapy of Congestive Heart Disease, Am. J. M. Sc. *209:* 33-41 (Jan.) 1945.

Literature giving further details about Digilanid and Physician's Trial Supply are available on request.

68 CHARLTON STREET, NEW YORK 14, NEW YORK

The transfer of practice became effective September 1.

During his years at Swanville Dr. Simons compiled an outstanding record of service to the public and to the medical profession. He has served as president of the Minnesota State Medical Association and the Upper Mississippi Medical Society. He was senior physician at the state tuberculosis sanatorium at Walker and served as chief of the medical services unit of the Minnesota Division of Social Welfare. He was one of the twenty-one state physicians who organized the Blue Shield medical insurance plan, and is still one of its directors. He is at present a trustee of the Minnesota Medical Foundation at the University of Minnesota. In addition to these duties he conducted his private practice at Swanville for over twenty-five years and even found time to serve as mayor for several years.

* * *

Dr. E. M. James, who has opened a medical laboratory at 657 Lowry Medical Arts Building, Saint Paul, is also continuing his work as pathologist for St. Joseph's Hospital, Saint Paul.

* * *

Dr. Justin C. Lannin, Mabel, was honored for his thirty-nine years of service at ceremonies held in Mabel on July 16 and attended by more than 1,000 persons. Dr. Lannin was presented with a scroll commemorating the occasion and was given luggage and a wrist watch by Mabel businessmen and other friends. Present during the ceremonies were Dr. Lannin's wife and his two sons, both physicians, Dr. Bernard G. Lannin and Dr. Donald R. Lannin, of Saint Paul.

A graduate of McGill University in Montreal, Canada, Dr. J. C. Lannin came to the United States in 1910 and located at Caledonia. After a year there, he moved to Mabel, where he has since practiced.

HOSPITAL NEWS

At the organizational meeting of the medical staff of the new **Zumbrota Community Hospital,** held in Zumbrota on June 29, Dr. M. G. Flom was elected chief-of-staff, and Dr. Oliver E. H. Larson, secretary.

* * *

First steps in the organization of a women's auxiliary unit for the new **Community Memorial Hospital** in Blue Earth were taken on July 21 when more than seventy-five women met at the hospital at the invitation of Mrs. Dora McKee, the superintendent. Following organization, the group planned to supply the various needs of the hospital. Its first project was to prepare new hospital linens. Future projects may include raising funds, providing volunteer workers, and canning food for hospital use.

* * *

The **Valleyview Hospital and Sanitarium** near Jordan was dedicated on July 16. A chronic-disease institution, the hospital was renovated and remodeled through the efforts of Dr. Joseph C. Michael of Minneapolis.

* * *

A meeting of men of the St. Wenceslaus parish in Jackson was held on July 23 to discuss the commuinty hospital situation and to find ways to assist the Sisters of Charity in the operation of the **Hal-**

loran Hospital. A committee was formed to try to solve the problem of the lack of proper facilities due to the hospital's crowded condition.

* * *

Cornerstone-laying ceremonies for the new **St. Louis County Infirmary,** adjoining St. Luke's Hospital, Duluth, were held on July 18 by the Minnesota Grand Lodge of AF&AM. Among lodge officials taking part in the ceremonies was Dr. B. S. Adams, Hibbing, past grand master of the lodge.

* * *

The blessing and dedication ceremony of the site for the **St. John's Hospital,** to be built at Red Lake Falls, was held on July 9. Among physicians taking part in the ground-breaking ceremonies were Dr. L. N. Dale, Red Lake Falls, and Dr. C. G. Uhley and Dr. O. K. Behr, both of Crookston.

* * *

The dedication of the new **St. Michael's Hospital** in Sauk Centre was held on July 9. The size of the crowd attending the ceremonies, in spite of overcast skies, was estimated at from 3,000 to 5,000 persons. As principal speaker on the dedicatory program, Dr. Alfred W. Adson, Rochester, predicted that within five years the $700,000 institution would be doubled in size. "Someone was smart," he stated, "when they planned this institution to provide for fifty additional beds. With an area serving 18,000 people, in five years you're going to need them."

* * *

Three new operating rooms and one for application of casts have been constructed at **St. Mary's Hospital,** Rochester. The rooms include two for major and one for minor orthopedic surgery. Their construction is part of a $215,000 renovation plan for the fifth and sixth floors of the hospital's east surgical wing. The addition of the four rooms brings the total of operating rooms at the hospital to twenty.

BLUE SHIELD NEWS

During recent months members of the Blue Shield and Blue Cross staff have been invited to attend hospital staff meetings to discuss how the doctor can assist Blue Cross and Blue Shield. The purpose of such meetings has been to secure the full co-operation of staff physicians in correcting serious situations that have arisen regarding both non-profit plans. Due to the close affiliation of Blue Cross with Blue Shield, the physician's own plan of prepaid medical care, the problems which affect one plan will likewise affect the other. Blue Cross and Blue Shield cannot exist without the support and co-operation of the doctors and the hospitals. For the benefits of those who have not attended a hospital staff meeting where these problems have been discussed, briefly these are the problems.

Minnesota Blue Cross paid to hospitals for subscriber care approximately $400,000 more in 1949 than was anticipated. The final analysis shows that this increase of hospital utilization was caused by various items. Perhaps the largest single item that affected this increase was the fact that many patients were being hospitalized solely for services which appear to be in many instances purely health examinations. It is

realized that some of these hospitalized cases are a result of undue pressure placed on the doctor by the patient who feels that he has a hospital contract that does provide for diagnostic work. It was not the original intent of Blue Cross to provide for services of this type which in most instances do not require an overnight stay in the hospital and Blue Cross does not provide benefits for outpatient care except for accidents and minor surgery including such service which cannot be provided in the doctor's office. A new Blue Cross contract has been approved and will supersede the one now in existence. This contract excludes benefits for diagnostic work; however, it will not replace the present contract until the expiration date of each contract. In the meantime, we can only request the doctors to advise their patients that diagnostic services which do not require an overnight stay in the hospital should be done in the doctor's office or paid for by the patient if outpatient care is necessary in the hospital.

The Blue Cross problem is mainly that diagnostic cases are kept in the hospital over night whereas formerly they were outpatient cases.

The hospital drug bills for 1949 increased over 1948 by $1.37 per case resulting in an over-all increase of $200,000 for the year. Laboratory work increased $1.47 per case or approximately $210,000 for the year.

It is not the intent of either Blue Cross or Blue Shield to advise the medical profession or the hospitals as to how they should practice medicine or operate the hospitals. It is merely the intent to point out some of the situations that have arisen and ask the co-operation of the medical profession in attempting to eliminate abuses so that the cost to Blue Cross can be reduced, and thereby keep the rates within the means of the low income groups of people. Many people have the erroneous impression that Blue Cross and Blue Shield lower the cost of medical care. They do not and cannot lower it one penny. They only spread it. Doctor Hawley, director of the American College of Surgeons, says: "The utilization rate of Blue Cross has been rising steadily for the past six or seven years. Also, during this same period, hospital charges have increased tremendously. So Blue Cross has been caught between the upper and nether millstones of spiraling costs and increasing utilization. We cannot keep this up forever. One of these days Blue Cross is going to be too expensive for poor people. When that day comes, we are going to have compulsory health insurance. Poor people can vote, you know, even if they cannot afford Blue Cross."

Both the Blue Cross and Blue Shield contracts specify that no allowance will be made for the treatment of any condition which was known by the subscriber or any of his family dependents to exist at the time the contract application is received in the Blue Cross, Blue Shield office until ten months after the contract has been in effect. It has been the policy of this office to consult the subscriber's physician regarding this informaiton; it is believed that the physician is in the position to furnish such information and also that he would assist in governing the control of this factor which is of vital importance to the success of the Plans.

In some instances it is becoming increasingly difficult to obtain specific information. Much of the information relative to foreknown conditions is inclined to be vague rather than specific enough to establish a date of knowledge of the condition. It is realized that in many instances it is difficult to make a definite statement concerning this matter; however, it is believed that the physician in obtaining a history is in a position to know whether that condition could or could not have been present for a specified length of time.

Information which is difficult to interpret could result in increased utilization. For example, if Blue Shield were to make allowances for ten cholecystectomies in the course of a month which rightfully should not be paid, utilization for that month would increase by $1,250. This may not appear to be very much in an over-all picture of approximately $200,000 allowed for a month; however, if this situation continues to increase it is easily possible to foresee an excessive increase in utilization. The same situation also applies to Blue Cross and it is reasonable to assume that if allowances were made on ten cholecystectomies the utilization would run from $1,500 to $2,000 per month. The co-operation of the medical profession in furnishing correct and specific information on this question is requested for it is assumed that the medical profession does not wish to place unnecessary burdens on these two non-profit plans.

Blue Shield payments for June totaled $184,427.37 bringing the total for the first six months to $954,685.20. Enrollment of new Blue Shield subscribers shows an increase for this year of 99,528, enrollment as of June 30, 1950 is 360,029. Blue Cross enrollment as of the same date totaled 1,033,139 participant subscribers. The average fee per Blue Shield claim for the first six months of 1950 is $40.05 as compared with $38.92 for 1949. June payments covered 4,788 Blue Shield claims; 23,385 claims were paid for the six month's period.

October will mark the opening of the second Blue Cross-Blue Shield non-group enrollment campaign which will run from October 1 through October 22, 1950. A total of 495 advertisements in twenty-six non-metropolitan (out-state) dailies, eighty-five county weeklies, the *Minneapolis Sunday Tribune* and the *St. Paul Sunday Pioneer Press* will tell the people of Minnesota why and how they should enroll in Blue Shield and Blue Cross. To create interest in the campaign and to help people in each area get information quickly since there is a definite time limit on the campaign, the doctors are being requested to display non-group literature and a poster in their waiting rooms.

BOOK REVIEWS

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical Libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

THE ESOPHAGUS AND PHARYNX IN ACTION. William Lerche, M.D. Fellow American College of Surgeons; Founder Member and Honorary Member of the American Association for Thoracic Surgery; formerly Associate Professor of Surgery, University of Minnesota, Minneapolis. 222 pages. Illus. Price $5.50, cloth. Springfield, Illinois: Charles C Thomas, 1950.

THE ANTIHISTAMINES—THEIR CLINICAL APPLICATION. Samuel M. Feinberg, M.D., Associate Professor of Medicine, Chief of Division of Allergy and Director of Allergy Research Laboratory; Saul Malkiel, Ph. D., M.D., Assistant Professor of Medicine Director of Research, Allergy Research Laboratory; Alan R. Feinberg, M.D., Clinical Assistant in Medicine, Attending Physician in Allergy Clinic. 291 pages. Illus. Price, $4.00, cloth. Chicago: Year Book Publishers, 1950.

PHYSICIAN'S HANDBOOK. Sixth Edition. Marcus A. Krupp, M.D., Assistant Clinical Professor of Medicine, Stanford University School of Medicine, Director Clinical Pathology, Veterans Administration Hospital, San Francisco; Norman J. Sweet, M.D., Assistant Professor of Medicine, University of California School of Medicine, San Francisco; Ernest Jawetz, Ph.D., M.D., Associate Professor of Bacteriology and Lecturer in Medicine and Pediatrics, University of California School of Medicine, San Francisco; and Charles D. Armstrong, M.D., Clinical Instructor in Medicine, Stanford University School of Medicine. 380 pages. Illus. Price $2.50, paper cover. Palo Alto, California: University Medical Publishers, 1950.

SAINTS, SINNERS AND PSYCHIATRY. Camilla M. Anderson, M.D., Assistant Clinical Professor of Psychiatry, University of Utah. 206 pages, including index. Price $2.95. Philadelphia: J. B. Lippincott Company, 1950.

This is a well-written book in about the simplest and most understandable language possible, and can be highly recommended to general practitioners and to intelligent laymen.

It clearly describes the dynamics of behavior by showing how everyone has his individual self-image, both physical and psychological. This self-image is composed of many parts, and each part is conceived of as having both structure and function, that is, anatomy and physiology. Each organ does a specific job. Every character trait carries with it the expectation of a result to be obtained through the use of it.

The psychological self-image is formed early in life as a result of the child's experiences with the significant people in his environment. Once a character trait has been formed, that is, becomes structuralized, it becomes compulsive, and its functional results are taken for granted.

Every individual has as his motivation as well as his road map for living, the maintenance of his self-concept, and lives out a compulsive and therefore unrealistic and neurotic pattern of behavior through his need to maintain his self-concept. As long as he can do this successfully, he feels comfortable. But whenever he feels that there is a threat to the integrity of any portion of his self-structure (physical or psychological), or whenever a part of his structure does not function in the anticipated manner, he will experience a psychic pain which is anxiety.

Whenever the structure of the psychological self-image is broken, the pain or anxiety felt is known as guilt *(sinners)*.

Whenever the function of the psychological self-image is disturbed, the anxiety feeling aroused thereby is felt as helplessness, frustrated entitlement, or outraged virtue *(saints)*.

Anxiety may be experienced in pure form, but more commonly in the form of one or more of three reactions: (1) reaction against or attack upon the anxiety-provoking situation with some degree of rage or resentment, (2) withdrawal from the situation or paralysis of all attack resources, (3) conversion of the attack forces into any type of physical symptom.

These reactions do not constitute the neurotic illness but are merely symptomatic of the presence of anxiety. The essence of neurosis may be found in one's self-concept, which in turn is to be found in one's assumptions, the things one takes for granted, one's beliefs. And the severity of the neurotic disability is determined not by the discrepancy between the assumptions and reality, but rather by the discrepancy between one's assumptions and the assumptions of culture with which one tries to identify.

Psychotherapy involves two processes. One, the clarification of the individual's assumptions; the other, establishment of new assumptions more realistically oriented. Mental health becomes a fact as habitual defense mechanisms are discarded and one can accept himself as he is *(psychiatry)*.

and gynecological information in his handbook which can be used to refresh one's memory on a specific problem utilizing a minimum of time.

The book contains charts for normal hematological values, normal blood chemistry values, normal renal function and urine values, hematological changes during pregnancy, blood chemistry values during pregnancy, miscellaneous laboratory values, cardio-vascular changes during pregnancy, tables of approximate equivalents and an obstetrical calender. The above information is on the inner side of the front and back covers.

There are two sections to the handbook. Section I has twenty-nine chapters; each chapter is in outline form, plus charts, pictures and diagrams regarding the specific problem of obstetrics under discussion. Section II contains ten short chapters on Diagnostic Gynecology. Space does not permit a detailed analysis of each chapter; however, the chapter regarding Emotional Aspects of Pregnancy is one which merits special citation. This phase of obstetrics is one which is often neglected in medical texts and not too seriously considered by busy practitioners.

The author has included standard obstetrical information and procedures in the text. He also describes some of his personal techniques and "tricks of trade."

The book is pocket size and could be used as a handy reference for emergency information, for hospital work, at home deliveries and at the office.

evaporated milk and Dextri-Maltose formulas

Infant feeding formulas of cow's milk, water and Dextri-Maltose* have been prescribed for almost four decades, by two generations of physicians.

LACTUM and DALACTUM bring new convenience to such formulas. They are prepared for use simply by adding water. A one-to-one dilution supplies 20 calories per fluid ounce and is suitable for most infants.

LACTUM is a whole milk formula designed for full term infants with normal nutritional requirements.

DALACTUM is a low fat formula for both premature and full term infants with poor fat tolerance.

AUREOMYCIN CRYSTALLINE
in Tularemia

Tularemia, which is a serious problem in many parts of this country, can be successfully treated with aureomycin.

All types of tularemic infection, with or without complications, respond promptly to the administration of this antibiotic.

AUREO-
MYCIN

AUREOMYCIN has also been found effective for the control of the following infections: acute amebiasis, bacterial and virus-like infections of the eye, bacteroides septicemia, boutonneuse fever, acute brucellosis, common infections of the uterus and adnexa, resistant gonorrhea, Gram-positive infections (including those caused by streptococci, staphylococci, and pneumococci), Gram-negative infections (including those caused by the coli-aerogenes group), granuloma inguinale, *H. influenzae* infections, lymphogranuloma venereum, primary atypical pneumonia, psittacosis (parrot fever), Q fever, rickettsialpox, Rocky Mountain spotted fever, subacute bacterial endocarditis resistant to penicillin, surgical infections, tick-bite fever (African), and typhus.

Capsules: Bottles of 25, 50 mg. each capsule. Bottles of 16, 250 mg. each capsule.
Ophthalmic: Vials of 25 mg. with dropper; solution prepared by adding 5 cc. of distilled water.

Announcing new **CUSTOM-BUILT**

the
500 MA
vertical
control

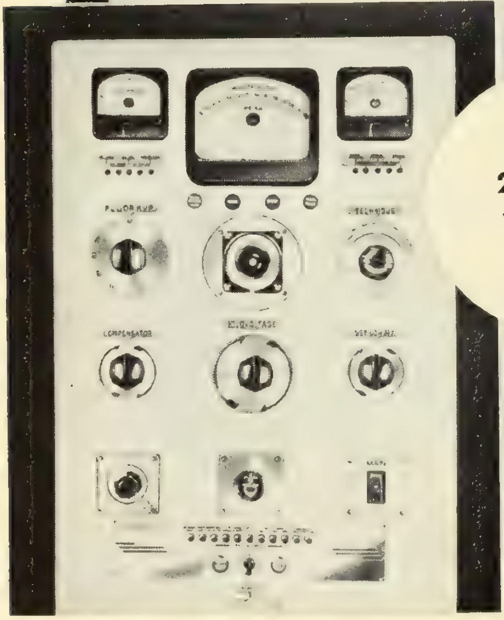
AGAIN, Keleket sets the pace with a money-saving development. NOW—ALL UNITS—200 MA, 300 MA and 500 MA use the SAME TRANSFORMER and CONTROL which can be produced at a savings... passed on to you!

By standardizing many parts of the world-famous Multicrons, Keleket is able to offer custom-built units... which fit your individual requirements exactly . . . at most attractive prices.

Every unit is equipped with the same functionally designed cabinet, finished in handsome Kelekote.

This unit may be installed permanently, even in a wall, with no worry about alterations . . . should your future technic requirements call for the higher capacity Multicrons.

All units . . . 200 MA, 300 MA and 500 MA... include the features which have made Keleket Multicron Controls so popular with radiologists . . . for flexibility, convenience and accuracy.



the
200 MA
vertical
control

The controls are rated as follows:

DIAGNOSTIC

200 MA unit—125KVP at any MA from 25 to 200
300 MA unit—125 KVP at any MA from 25 to 300
500 MA unit—125 KVP at any MA from 25 to 500

THERAPY

All units—140 KVP to 10 MA

An optional Photo-Timer and Photo-Timing pushbutton control can be mounted in the vertical controls. Unit is so designed and engineered that only minor alterations are required to effect increased capacity and timer changes.

Telephone or write for complete details

If You Are Called Into Service—
If You Are Too Old to Be Called Into Service—

In either event the rebellion in Korea affects your pocketbook in a major way, which will be reflected in your accounts receivable.

Soldiers Relief from their financial obligations has again been invoked making it impossible to enforce collection against anyone in the Armed Forces.

With our many years of valuable experience in handling the accounts for over 1,000 professional men, there is now an influx of professional accounts to this office due from patients about to enter Military Service where the possibility of immediate collection appears very problematical.

Our Recommendations

Based upon our experience in liquidation of accounts prior to, during, and after World War II

(1) Concentrate effort on the collection of accounts against patients who may be called in the Armed Forces.

(2) THE TIME TO COLLECT IS NOW because with inevitable continued inflation, increased salaries and wages, farm prices, commodity prices, there will be more money in circulation.

(3) That if you already have been called into the service or anticipate being called that you permit this qualified organization to act as your liquidating agent.

Our many years of experience handling accounts in the professional field plus our contractual relationship with fifty trade associations extending from coast to coast, proves we are rendering outstanding service.

Professional, commercial trade associations, and bank recommendations furnished.

"In addition to the relief of hot flashes and other undesirable symptoms (of the climacteric), a feeling of well-being or tonic effect was frequently noted" after administration of "Premarin."

Harding, F. E.: West. J. Surg. Obst. & Gynec. 52:31 (Jan.) 1944

"All patients (53) described a sense of well-being" following "Premarin" therapy for menopausal symptoms.

Neustaedter, T.: Am. J. Obst. & Gynec. 46:530 (Oct.) 1943.

"It ('Premarin') gives to the patient a feeling of well-being."

Glass, S. J., and Rosenblum, G.: J. Clin. Endocrinol. 3:95 (Feb.) 1943

"General tonic effects were noteworthy and the greatest percentage of patients who expressed clear-cut preferences for any drug designated 'Premarin.'"

Perloff, W. H.: Am. J. Obst. & Gynec. 58:684 (Oct.) 1949.

ACCEPTED COUNCIL ON PHARMACY AND CHEMISTRY AMERICAN MEDICAL ASSOCIATION

Four potencies of "Premarin" permit flexibility of dosage: 2.5 mg., 1.25 mg., 0.625 mg., and 0.3 mg. tablets; also in liquid form, 0.625 mg. in each 4 cc. (1 teaspoonful).

the clinicians' evidence of the "plus" in "PREMARIN"® therapy

Estrogenic Substances (water-soluble)
also known as Conjugated Estrogens (equine)

While sodium estrone sulfate is the principal estrogen in "Premarin," other equine estrogens...estradiol, equilin, equilenin, hippulin...are probably also present in varying amounts as water-soluble conjugates.

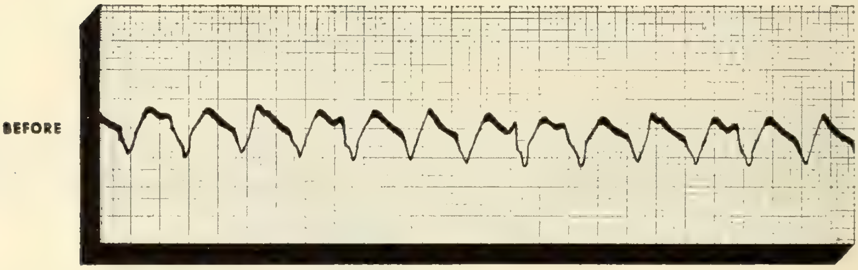
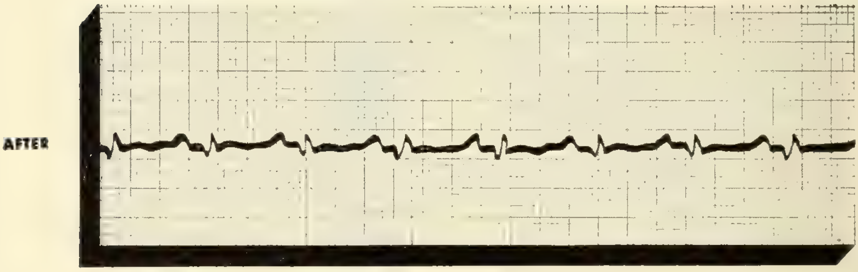
A New Drug..for the treatment of ventricular arrhythmias



Lead II. Ventricular tachycardia persisting after six days of oral quinidine therapy (8 Gm. per day).



Lead II. Normal sinus rhythm after oral Pronestyl therapy.

Effective in some patients with ventricular tachycardia who failed to respond to quinidine

PRONESTYL *Hydrochloride*

Squibb Procaine Amide Hydrochloride

SQUIBB

"PRONESTYL" IS A TRADEMARK OF E. R. SQUIBB & SONS

new product brief

PRONESTYL *Hydrochloride*

Squibb Procaine Amide Hydrochloride

for the treatment of ventricular arrhythmias

What is it?

Pronestyl Hydrochloride is Squibb procaine amide hydrochloride. Structurally, Pronestyl differs from procaine only by the presence of the amide grouping (.CO.NH.) in Pronestyl where procaine has the ester grouping (.CO.O.)

How does it act?

The action of Pronestyl is probably due to a direct depressant action on the ventricular muscle. In auricular arrhythmias, preliminary observations indicate that Pronestyl slows auricular rate but usually does not re-establish normal sinus rhythm. At present, Pronestyl is not recommended in the treatment of auricular arrhythmias.

When is it indicated?

In conscious patients, for the treatment of ventricular arrhythmias.

During anesthesia, to correct cardiac arrhythmias.

What are its advantages in ventricular arrhythmias?

As compared with quinidine: Unlike quinidine, no important toxic symptoms have been reported following the use of Pronestyl orally. In therapeutic dosage, Pronestyl orally does not produce the nausea, vomiting, and diarrhea often caused by quinidine. At high oral dosage, these symptoms may appear.

Whereas intravenous administration of quinidine is hazardous and unpredictable, Pronestyl may be given intravenously with relative safety.

Pronestyl has been found effective in some patients who failed to respond to quinidine.

As compared with procaine: For arrhythmias, procaine is used only in anesthetized patients because its dose in unanesthetized patients is too toxic for clinical use. Pronestyl can be used in conscious and anesthetized patients.

Intravenously, Pronestyl is much less toxic than procaine. In the recommended intravenous dosage, Pronestyl does not cause the central nervous system stimulation typical of procaine in conscious patients.

Procaine is unstable, being rapidly hydrolyzed in the plasma to para-aminobenzoic acid and diethylaminoethanol. Pronestyl is not affected by the plasma procaine esterase, consequently it is much longer acting than procaine.

Procaine is not used orally because of its instability in the organism; Pronestyl can be used orally and intravenously.

What are its side effects?

Oral administration of Pronestyl in doses of 3-6 grams per day, for periods of time varying from 2 days to 3 months, produced no toxic effects as evidenced by studies of the blood count, urine, liver function, blood pressure, and electrocardiogram. Intravenous administration to patients without ventricular tachycardia produced only a moderate and transient hypotensive effect in about one-third of the subjects. However, during intravenous administration to patients with ventricular tachycardia, a striking hypotensive effect was almost invariably present. This disappeared concurrently with the establishment of a normal rhythm. Further studies are in progress to see whether the drug may be given intravenously over a period of time longer than five minutes so as to revert the ventricular tachycardia without causing hypotension. That this may be possible is indicated by the fact that some episodes of ventricular tachycardia have been successfully treated by oral administration without significant change in blood pressure. Electrocardiographic changes: prolongation of QRS and QT intervals and occasional diminution in voltage of QRS and T waves have occurred.

What is the dosage?

IN CONSCIOUS PATIENTS

For the treatment of ventricular tachycardia:

ORALLY: 1 Gm. followed by 0.5-1.0 Gm. every four to six hours as indicated.

INTRAVENOUSLY: 200-1000 mg. (2 to 10 cc. Pronestyl Hydrochloride Solution). *Caution—administer no more than 200 mg. (2 cc.) per minute.*

Hypotension may occur during intravenous use in conscious patients. As a precautionary measure, administer at a rate no greater than 200 mg. (2 cc.) per minute to a total of no more than 1 Gm. Electrocardiographic tracings should be made during injection so that injection may be discontinued when tachycardia is interrupted. Blood pressure recordings should be made frequently during injection. If marked hypotension occurs, rate of injection should be slowed or stopped.

For the treatment of runs of ventricular extrasystoles:

ORALLY: 0.5 Gm. (2 capsules) every four to six hours as indicated.

IN ANESTHESIA

During anesthesia, to correct ventricular arrhythmias:

INTRAVENOUSLY: 100-500 mg. (1 to 5 cc. Pronestyl Hydrochloride Solution). *Caution – administer no more than 200 mg. (2 cc.) per minute.*

How is it supplied?

Pronestyl Hydrochloride Capsules, 0.25 Gm., bottles of 100 and 1000.

Pronestyl Hydrochloride Solution, 100 mg. per cc., in 10 cc. vials.

PROVIDES PROTECTION WITHOUT IRRITATION

Evidence obtained by direct-color photography shows that the cervix remains occluded for as long as ten hours after an application of "RAMSES"* Vaginal Jelly.

"RAMSES" Vaginal Jelly immobilizes sperm in the fastest time recognized under the authoritative Brown and Gamble method of measuring the spermatocidal power of vaginal jellies or creams. This has been established by repeated tests for spermatocidal activity conducted by an accredited independent laboratory.

Clinical observation of patients receiving daily applications of "RAMSES" Vaginal Jelly for three-week periods reveals no evidence of irritation or other untoward effect.

"RAMSES" Vaginal Jelly is acceptable to even the most fastidious patient because it provides efficient protection without leakage or excessive lubrication. It is available at all pharmacies in regular and large tubes; the regular tube is also available in a package containing a measured applicator.

ACTIVE INGREDIENTS: Dodecaethyleneglycol Monolaurate 5%, Boric Acid 1%, Alcohol 5%.

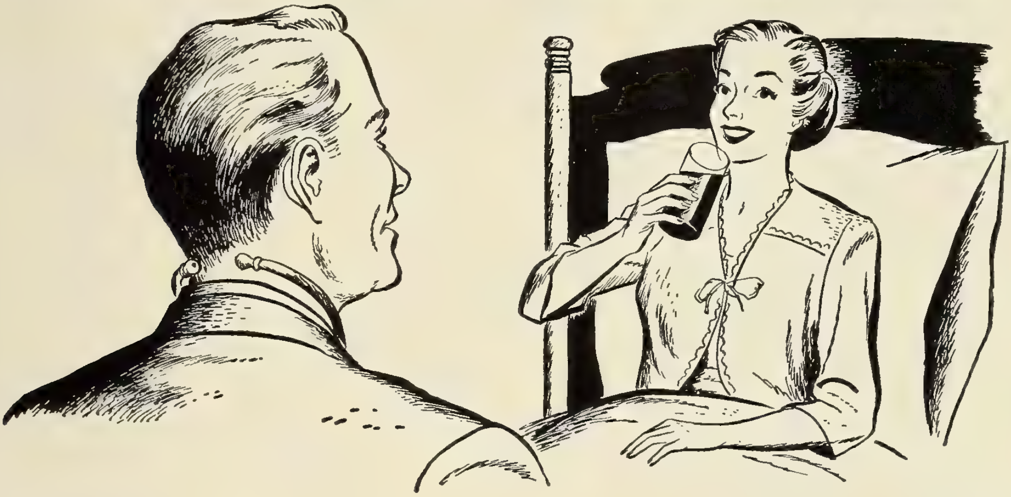
REGARDLESS OF INDICATED THERAPY

Nutrition is a Primary Factor



Whether the condition under treatment is an acute infection, a bowel upset, an injury or a metabolic derangement, nutrition is always a primary factor in therapy. Regardless of other indicated measures, nutritional adequacy is essential for prompt recovery.

When dietary supplementation is the indicated means of increasing the nutrient intake, the food drink, Ovaltine in milk, can prove highly beneficial. Providing significant amounts of all nutrients considered essential, it virtually assures dietary adequacy when the recommended three glassfuls daily are taken in conjunction with even a fair diet.

Temptingly delicious and readily digested, this dietary supplement fits well into the framework of most indicated diets, and finds ready patient acceptance. Its generous nutrient content is detailed in the table below.

THE WANDER COMPANY, 360 N. MICHIGAN AVE., CHICAGO 1, ILL.

OVALTINE
OVALTINE

Ovaltine

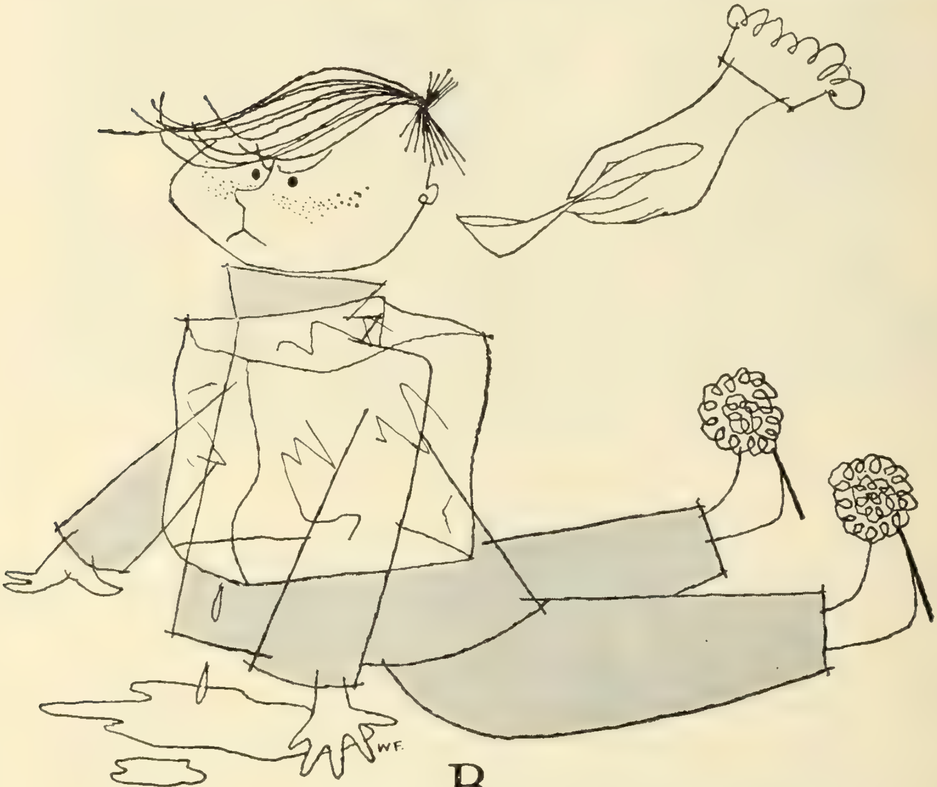
Three servings of Ovaltine, each made of ½ oz. of Ovaltine and 8 oz. of whole milk, provide:*

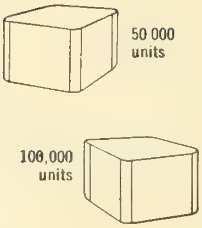
PROTEIN	32 Gm.	VITAMIN A	3000 I.U.
FAT	32 Gm.	VITAMIN B_1	1.16 mg.
CARBOHYDRATE	65 Gm.	RIBOFLAVIN	2.0 mg.
CALCIUM	1.12 Gm.	NIACIN	6.8 mg.
PHOSPHORUS	0.94 Gm	VITAMIN C	30.0 mg.
IRON	12 mg.	VITAMIN D	417 I.U.
COPPER	0.5 mg.	CALORIES	676

*Based on average reported values for milk.

Two kinds, Plain and Chocolate Flavored. Serving for serving, they are virtually identical in nutritional content.

When little patients
turn a cold shoulder





BAD-TASTING medicine usually meets a chilly reception in small fry circles. But if Junior likes candy, you can melt the ice by prescribing *Dulcet* PENICILLIN Tablets. These small, easy-to-take cubes taste like a confection, yet pack a potent antibiotic wallop—50,000 or 100,000 units penicillin G potassium per tablet. Each *Dulcet* Tablet is buffered with 0.25 Gm. calcium carbonate to minimize loss of therapeutic value through destruction in the stomach. From first to last in every bottle, the tablets are carefully standardized for accurate dosage, stable indefinitely at room temperature. • *Dulcet* PENICILLIN Tablets are in pharmacies everywhere, in bottles of 12 and 100. Prescribe them the next time penicillin is indicated. Abbott

MILK-BORNE BRUCELLOSIS IN MINNESOTA

C. B. NELSON, M.D., M.P.H., and MARY GIBLIN, M.S.
Minneapolis, Minnesota

THERE have been 3,074 cases of human brucellosis reported to the Minnesota State Department of Health in the ten-year period, 1940-1949. It is estimated that approximately 25 per cent of the reported cases in this state are due to the ingestion of raw dairy products, chiefly raw milk and cream.[5] Therefore it can be assumed that in approximately 767 of the cases reported during this period infection with Brucella organisms has occurred in this manner.

The presence of viable Brucella organisms in market milk, including milk from certified herds, has been demonstrated on numerous occasions. Outbreaks of human brucellosis due to *Brucella suis* in raw milk from cows have been reported by Beattie and Rice,[1] Horning,[4] and Borts.[2] Beattie and Rice state that outbreaks of brucellosis due to *Brucella abortus* (bovine) on raw milk routes are relatively uncommon, and that the occurrence of more than four or five cases on a single raw milk route is rare. Steele and Hastings[7] report an outbreak of twenty-eight cases of human brucellosis traceable to raw milk. *Brucella abortus* (bovine) was isolated from blood cultures from two of the cases. They state that this is the first large brucellosis epidemic due to *Brucella abortus* (bovine) that has been reported. Damon[3] reports the isolation of *Brucella melitensis* from milk of cows.

The Minnesota State Health Department records of cases of human brucellosis attributed to consumption of raw milk indicate that the source of raw milk usually is the herd on the patient's farm or herds belonging to friends or relatives.[5] However, during the ten-year period, 1940-1949, there were 450 reported cases of brucellosis in which the source suspected by the reporting physician was raw milk from a supply other than the herd on the patient's farm. Included in these 450 cases were ninety-six cases attributed to a common source in forty-one dairies. Twenty-eight dairies were the source of two cases each; nine dairies, three cases each; two dairies, four cases each, and one dairy, five cases. In most instances the cases were spread over a considerable period of time.

The outbreak of three known cases of brucellosis in patrons of a raw milk dairy is reported in more detail since *Brucella abortus* (bovine) was isolated from raw milk purchased at a store selling milk from the suspected supply (Table I).

Case	Age	Date of Onset	Agglutination with Brucella antigen	Blood Culture
1	65	8-15-49	(9-23-49) +1:1280	(9-23-49) No growth
2	25	1-50	(4-19-50) +1:1280 (5-2-50) +1:1280	(4-23-50) *Br. abortus* (bovine)
3	42	2-24-50	(3-4-50) +1:5120	(4-10-50) No growth

These three patients all had symptoms compatible with the diagnosis of acute brucellosis. The diagnosis was confirmed in Case 2 by the isolation of *Brucella abortus* (bovine) from a blood culture, and in Cases 1 and 3 by high agglutination titers with Brucella antigen. The possibility of sources of infection other than raw milk from the suspected supply was ruled out by history.

Dr. Nelson is Director, Division of Epidemiology, Minnesota Department of Health.
Miss Giblin is Director, Division of Microbiology, Minnesota Department of Health.

The dairy owner was not co-operative but volunteered the information that he supplied approximately 400 quarts of raw milk daily to his patrons through retail and wholesale trade. Information from the State Live Stock Sanitary Board revealed that the suspected herd had been tested for Bang's disease in 1947. One "reactor" and three "suspects" were found, and the reactor was removed from the herd. At the time of the present investigation the owner refused to have his herd tested or to make arrangements for pasteurization of the milk.* A quart of the suspected raw milk labeled "Natural Milk" was purchased March 29 in the hope of obtaining irrefutable proof that the milk from the herd contained viable Brucella organisms. A sample of this milk examined by Dr. M. H. Roepke, Professor of Veterinary Medicine, University of Minnesota, showed a strongly positive ring test. A portion of the milk was also submitted to the Section of Medical Laboratories, Minnesota Department of Health. Two guinea pigs were inoculated subcutaneously on March 31, 1950, one with the sediment of the centrifuged specimen, the other with cream of the centrifuged specimen. The pigs were sacrificed on May 17, 1950, at which time agglutination was present 1:640 with Brucella antigen in blood from both animals. Cultures from the spleen of both pigs showed Gram-negative, non-motile organisms identified as *Brucella abortus* (bovine) on June 15, 1950.

The above report was sufficient evidence to justify the Live Stock Sanitary Board's placing a quarantine on the herd. This provided that no raw milk could be sold. The owner then arranged for Bang testing of the herd, which disclosed twenty-nine negative animals and two reactors. The reactors were removed from the herd and the quarantine was raised by the Live Stock Sanitary Board.

Summary and Conclusions

An outbreak of three cases of human brucellosis traceable to a commercial raw milk supply is briefly reported. The causative organism, *Brucella abortus* (bovine), was isolated from the market supply of raw milk. The outbreak demonstrates the difficulty that is encountered from time to time by official agencies in obtaining compliance with good public health practice.

Although the cases of human brucellosis that are traceable to raw milk purchased from commercial raw milk dealers will be eliminated by the amended pasteurization law, the cases traceable to private sources of raw milk will not be decreased. For this reason, public health education must continue until universal pasteurization of milk is practiced, including home supplies and milk purchased by the consumer directly from the farm. Apparently, reduction in the number of cases of human brucellosis from all sources in Minnesota continues to be dependent on the reduction of brucellosis in the animal reservoir, namely the livestock population of the state.

*As of July 1, 1950 the sale of raw milk in Minnesota is prohibited by law,[6] except as purchased for personal use at the dairy farm where it is produced.

THE RIGHTS OF THE COMMUNITY

Every community is entitled to safe water, food, and milk, and protection from unsafe disposal of wastes; to as safe an environment as we know how to provide including pure air; safe streets, homes, places of work, and places of education and recreation; to the best protection we know how to provide from the contagious diseases, including tuberculosis and the venereal diseases; access to good medical care and hospitalization when needed; to the best protection we known how to provide against the special hazards of maternity and infancy; to the best facilities we know how to provide for the healthy development of our children, including correction of crippling physical and mental defects; recognition and treatment of rheumatic fever and other heart disease, and to the knowledge and facilities necessary to prevent as many deaths as possible from cancer, heart disease, diabetes, and the other degenerative diseases.—William P. Shepard, M.D., *National Tuberculosis Association Bulletin*, October, 1949.

THE MANAGEMENT OF STATUS ASTHMATICUS

WILLIAM SAWYER EISENSTADT, M.D.
Minneapolis, Minnesota

STATUS ASTHMATICUS is an acute condition of severe, continuous asthma, unrelieved by injections of epinephrine even when repeated frequently and in increased dosage. When an acute asthmatic attack fails to subside and becomes refractory to the usual sympathomimetic medications which in the past gave relief, the dyspnea becomes more severe, the cough unproductive and the patient remains in a constant asthmatic state. The patient is critically ill and may die unless the attack of asthma is broken. When this occurs, its treatment taxes the ingenuity of the best clinician.

The above condition must not be confused with intractable asthma,[9] a chronic process usually associated with chronic bronchitis, bronchiectasis and pulmonary emphysema. These patients are usually difficult to control by the usual allergic management. The intervals between the acute paroxysms of asthma are seldom free of wheezing.

Status asthmaticus may occur in the acute extrinsic asthmatic as well as in the chronic intractable asthmatic. It occurs more frequently in the chronic intractable asthmatic (1) because of the difficulty in controlling the asthma adequately and (2) because the usual associated pulmonary pathology makes one more susceptible to bronchitic infection. This condition occurs less frequently in the extrinsic asthmatic and then it is usually due to specific sensitivities. When status asthmaticus occurs in the extrinsic asthmatic, the solution of the problem may be relatively simple, representing nothing more than the removal of the offending agent or agents from the patient's environment, or the removal of the patient from them.

Most of the fatalities in bronchial asthma occur in status asthmaticus. Death may be due to asphyxia or cardiac failure, but just as often, perhaps, it is due to exhaustion and dehydration.

The most consistent pathological finding in patients who have died in status asthmaticus[15] is the presence in the small, medium or large bronchi of thick, tenacious, gelatinous secretions which the patient was unable to raise. Much of the bronchial tree may be entirely occluded. In addition to these mucous plugs, edema of the bronchial walls and bronchospasm contribute to this bronchial occlusion.

When these patients are first seen, they give the classical picture[3] of severe asthma. They are usually in a sitting position with the body bending slightly forward from the waist, their hands grasping the edge of the bed or chair. The accessory muscles of respiration are forcibly in use, the face is drawn and ashen. The pallor may at times give way to cyanosis. Perspiration is profuse, for these patients are laboring for breath. Unconsciousness or disorientation may occur suddenly. The patient is terrified because of the repeated failure of the usual therapeutic medications. In addition, the family is anxious. There is a generalized spirit of hopelessness present and, not infrequently, the physician shares this feeling. This period of intense dyspnea may last from a few days to a week or two.

Examination of the chest elicits surprising findings to the uninitiated. Everyone is familiar with the "bandbox" heard in mild cases of asthma where there is only partial but wide-spread occlusion of the bronchi, as a result of which the sounds are widely distributed. In status asthmaticus, one finds areas of diminished and absent breath sounds, areas of quiet that to the experienced observer are ominous. In these patients, areas of the lungs have ceased to function normally because the bronchi serving those portions may be partially or totally occluded by thick, tenacious, gelatinous plugs of mucous. When one listens to such a chest, the need for prompt and vigorous therapeutic measures is immediately apparent.

The basic principles involved in a proper therapeutic approach in the treatment of status asthmaticus are (1) to increase the lumen of the respiratory passageway, and (2) to decrease the minute volume of respiration.

The following discussion sets forth a routine for the treatment of status asthmaticus which has produced the most favorable response.

Hospitalization.—Hospitalization should be insisted upon immediately. This will accomplish

---

Read before the annual meeting of the Minnesota State Medical Association, Duluth, Minnesota, June 13, 1950.

several indispensable purposes. First, the patient is removed from intimate contact with over-anxious relatives. Further, the hospital offers trained personnel, equipment and medicinal agents not readily available in the home.

Although most of the patients fall in the chronic intractable or infectious group, environmental factors should not be overlooked. Thus, the removal of the patient from the environment in which this condition developed may frequently be beneficial. If the status asthmaticus is due to pollen in the air, air conditioning with filtration is desirable if available. The ordinary precautions for the preparation of a dust-free room should be adhered to. It is wise to cover both the pillows and mattress with non-allergenic encasings. Flowers should be prohibited.

Reassurance.—As stated earlier, the patient is both terrified and panicky. This in turn will increase his exertional dyspnea. The patient fears that every breath may be his last. He must be reassured that the attack is controllable and that his cooperation is necessary to obtain results. A friendly, sympathetic and reassuring attitude on the part of the attending physician is a most vital and helpful therapeutic aid.

Cessation of all Epinephrine and Ephedrine Compounds.—We believe that this is the most important procedure employed. If nothing else can be done, this is the one thing to do. These patients have already received epinephrine, epinephrine-like, ephedrine and ephedrine-like compounds, to the point of nervous irritability and toxicity. They are "epinephrine-fast." Further epinephrine will only increase the patient's irritability and nervousness, produce tachycardia, palpitation, headache, pallor and weakness, with no effect on the dyspnea itself. The continuance of status asthmaticus proves the medication to have been ineffective, and a new start should be made. All sympathomimetic medications should be removed for a period of forty-eight to seventy-two hours, preferably the latter, and only then reintroduced. During this interval there is a strong temptation to reintroduce epinephrine, especially when the patient continues in relatively severe asthma and substitute therapy is of relatively little value. However, the discontinuance of epinephrine should be adhered to strongly during this interval.

When reintroduced, small quantities should be given, 0.3 to 0.5 c.c. (5 to 8 minims), and repeated as often as necessary, even within fifteen or thirty minutes. The smaller quantities will obviate the side effects of epinephrine and will produce the same therapeutic effect as larger quantities. It is preferable to use the aqueous (1-1000) epinephrine, rather than the prolonged type (1-500) in sesame oil, peanut oil, or gelatin. In a hospital there is no particular advantage in using the prolonged acting preparations for there is always the danger of overdosage from too rapid absorption, especially if the syringe is wet, with resultant side effects.

The problem in the treatment of status asthmaticus resolves itself into keeping the patient alive and as comfortable as possible for the next forty-eight to seventy-two hours following admission, for whatever the cause, when epinephrine is again introduced, invariably the patient will respond, especially if the other measures recommended in this paper are adhered to. If there is no accompanying infection in the bronchi, or the infection is minimal, the response will usually be immediate and fairly complete. If the accompanying infection is moderate, the response to epinephrine will be modified. The greater the accompanying infection, the less the response, but there will be a response. In the presence of infection, methods to combat the infection should be instituted immediately. The use of antibiotics, which are of great importance here, will be discussed subsequently.

Hydration.—This extremely important phase of treatment is almost always neglected. These patients are dehydrated.[12] They have been sick for a number of days without sleep, food or fluids. This is evidenced on admission by the very noticeable relative increase of the blood hemoglobin, red blood cell count, white blood cell count with a normal differential, along with a minimal increase of body temperature of about a degree. These soon return to normal after adequate hydration within twenty-four to forty-eight hours.

We routinely give 2 to 3 liters of 5 per cent glucose in distilled water and in isotonic sodium chloride solution alternately during the first two or three days of hospitalization. The addition of fluids will replace lost body water and bring about a positive water balance. They tend to thin out the bronchial secretions and thus promote expectoration of the thick, gelatinous, inspissated mucous plugs in the bronchi. The dextrose used in hydration therapy will supply needed calories and replace liver glycogen, badly depleted because of the previous repeated injections of epinephrine and the failure of the patient to take adequate nourishment. Glaser[4] suggests that this depletion of glycogen may be a factor in the development of epinephrine fastness.

In the past, hypertonic dextrose[6,8] solutions up to 50 per cent, given in quantities from 50 to 100 c.c., at intervals of six to eight hours, have been recommended. The idea was to produce dehydration of the lungs and thus lessen the edema of the bronchi. However, its accompanying effect of dehydrating the patient generally and thickening the bronchial secretions defeated one of the major objectives of treatment—the evacuation of the thick, inspissated mucous plugs. Because of this effect, the use of hypertonic dextrose solutions should be discarded.

Aminophyllin (Theophylline with Ethylenediamine).—The bronchodilating effect of aminophyllin intravenously at times is life-saving. Initially, the patient should receive 0.25 gram (3¾ grains) in 10 c.c. of diluent given slowly, preferably through a fine needle. If this dose is sufficient for symptomatic relief, it can be repeated every four to six hours. If relief is only partial, the dosage may be increased to 0.5 gram (7½ grains) in 20 c.c. of diluent. When given slowly and regulated to the patient's tolerance, the toxic effects of aminophyllin, such as vertigo, faintness, headache, tachycardia, palpitation, extreme flushing and sense of heat, substernal distress, and nausea and vomiting may be obviated. If they do occur, they may be minimal. In uncomplicated asthma, aminophyllin is not a dangerous drug. However, in the presence of cardiac complications caution must be used. The need for repeated intravenous injections of aminophyllin may be lessened by inserting 0.5 gram of aminophyllin per liter of fluid during the period of venoclysis.

The drug is also moderately effective when given rectally, either in suppository form or as a retention enema. The suppository contains 0.5 gram of aminophyllin. One-half gram of aminophyllin powder dissolved in 30 to 60 c.c. of tap water may be used as a retention enema. Given in this manner, it can be repeated every 6 to 8 hours.

Continuous intravenous aminophyllin in status asthmaticus has recently been introduced by Goodall and Unger.[5] Dosage consisted of up to 2 or 3 grams of aminophyllin dissolved in 2,000 c.c. of 5 per cent glucose in physiological salt solution or distilled water. The solution is given continuously over a twenty-four-hour period for several days until relief is afforded.

We see no particular advantage to this method, because the same coverage can be achieved by employing repeated intravenous injections of aminophyllin togther with rectal suppositories or retention enemas, without the extreme inconvenience to the patient of having a needle in his vein continuously for three or four days. This is extremely important when considering that the patient in status asthmaticus is already in extreme discomfort because of his marked dyspnea.

Occasionally patients may become refractory to the intravenous administration of aminophyllin. Recently Prigal[10] has recommended the aerosolization of aminophyllin when this occurs. The contents of a 10 c.c. (0.25 gram) or 20 c.c. (0.5 gram) ampule are nebulized at six- to eight-hour intervals. We have employed this procedure in a limited number of patients. Definitive judgment as to its relative value remains to be determined.

As in the case of "epinephrine fastness," when patients become refractory to aminophyllin by intraveous injection or aerosolization, its use should be discontinued, as further dosage will serve only to increase its toxic effects.

The use of intravenous aminophyllin in the treatment of children may be employed in the same manner, the dosage being .006 gram per kgm. (1/20 grain per pound).

Inhalation Therapy.—Inhalation therapy is directed toward decreasing the minute volume of respiration. It rarely of itself will interrupt status asthmaticus, one must be extremely careful to make the patient more comfortable by diminishing the extreme respiratory effort caused by the anoxia, by enriching the surrounding air with oxygen.

Oxygen may be employed with a tent, nasal catheter, or B.L.B. mask. At times, patients will rebel against the use of a tent because of a feeling of claustrophobia. This may increase their anxiety and nervousness, with resultant increase of their exertional dyspnea.

Barach[1] introduced a mixture of 80 per cent helium and 20 per cent oxygen, a mixture which has one-third the density of air. It therefore should diffuse more readily through the partially obstructed bronchioles. Its cost, however, is a limiting factor and, in our personal experience, oxygen has been equally as good.

Sedation.—In employing sedation, one must guard against over-sedation. However, measures to insure sleep and to overcome nervous tension are very necessary. We have used Demerol repeatedly, but with considerable caution. Used judiciously, it has proven to be a most effective drug. Its action[2] has apparently been twofold, sedation and a direct bronchodilating effect. In status asthmaticus, one must be extremely careful about respiratory depression and depression of the cough reflex, effects which are relatively minimal with Demerol as compared to the opiates.

In this connection, mention should be made concerning the use of morphine. In the past it has been used extensively, occasionally beneficially. However, one can say it should never be used in asthma, and especially so in status asthmaticus, where the patient is anoxic, exhausted and battling for life. Morphine depresses the respiratory center, diminishes the cough reflex and dries the bronchial secretions (especially if given with atropine). Thus, morphine actually promotes further anoxia—to the point of asphyxia—which is the very thing we are trying to combat. Because of the stagnation of the bronchial mucous plugs, the patient literally drowns in his own bronchial secretions. Vaughan[14] and Lamson[7] have shown that in many deaths due to asthma during status asthmaticus, morphine was given prior to death. The use of all other opiate derivatives should also be avoided.

The dosage of Demerol should be regulated with extreme care. Adults should never be given an initial dose exceeding 50 mgm. intramuscularly. It may later be necessary to increase to 75 mgm., and only rarely to 100 mgm. This can be repeated at six- to eight-hour intervals. It should be used for relatively short periods, three, four or five days, because of the possibility of addiction.[14] The routine use of Demerol for the relief of the usual acute attacks of bronchial asthma, as has been advocated, is to be condemned because of its properties of addiction. When using Demerol we have avoided using other sedatives, because of the possibility of over-sedation and the depression of all body functions.

Other sedative measures have been advocated by others.[15] Our experience with them is limited, but we will mention them briefly.

(1) Paraldehyde may be given rectally, 15 c.c. in 100 c.c. of olive oil at twelve-hour intervals.

2. Barbiturates may be given at four- to eight-hour intervals.

3. Chloral hydrate, 1 gram, and sodium bromide, 4 grams, may be given at four-hour intervals until the patient becomes drowsy; then stop.

4. A mixture of ether, 2 oz., and olive oil, 4 oz., mixed thoroughly, may be administered as a retention enema.

If any of the above are employed, only one should be used and not a combination. If used properly and carefully, sedation is extremely beneficial and life-saving. Its drastic use in an already exhausted and anoxic individual may be dangerous and disastrous.

Expectorants.—Methods which will thin out bronchial secretions and thus will help clear the bronchi of their mucous plugs are highly desirable. The best medication to achieve this is potassium iodide. It has been shown by Tuft[13] that the iodides are excreted in the bronchi in high concentration. Ten to fifteen drops of a saturated solution of potassium iodide taken orally are recommended four times daily until the patient is free of expectoration. If the patient is unable to take the drug orally, it may be given intravenously as sodium iodide. One gram may be added to a liter of the solution for intravenous administration by the drip method. If there is an intolerance to potassium iodide, enteric coated ammonium chloride tablets in 0.5 gram doses may be given four times daily.

In children, emetic doses of ipecac will produce forceful emesis and with it expectoration of mucous and clearing of the bronchial tree.

Manual Elevation of the Diaphragm.—In the presence of status asthmaticus physiological pulmonary emphysema is present. There is trapped air because of the partially and completely occluded bronchioles. Manual elevation of the diaphragm, as suggested by Gay,[2] is often followed by subjective relief as well as an increase in the vital capacity from 200 to 1000 c.c. The procedure is carried out as follows: the palm of either hand is placed underneath the ribs on one side and pushed upward and inward during the latter half of expiration. Then this is repeated on the other side. The escape of trapped air may frequently be heard as a wheeze. This procedure should be repeated three to four times daily.

Bronchoscopy.—Although we have not had occasion to use bronchoscopy, its use should not be overlooked. The mechanical removal of thick, tenacious mucus from the bronchi would appear to be a most reasonable treatment. Bronchoscopy has undoubtedly been restricted in its use because patients seem so gravely ill that any procedure which places a greater strain upon them would almost appear to be inadvisable. In skilled hands it is a relatively safe procedure and the risk is much less than that of possible asphyxia from the disease. However, preoperative medication should be kept at a minimum. Morphine and opiate derivatives are definitely to be avoided.

Antibiotic Therapy.—With the advent of antibiotic therapy, another powerful weapon has been added. As stated earlier, most patients in status asthmaticus belong in the chronic intractable or infectious group. Frequently an accompanying infection of the bronchi has been the cause of the status asthmaticus. The presence of infection is noted clinically by an increase in body temperature, elevated sedimentation rate, the presence of muco-purulent or purulent sputum, and leucocytosis with an increase in the polymorphonuclears.

Our routine is to use combined parenteral and aerosol penicillin therapy, so that the penicillin may reach the more superficial and deeper lying tissues of the bronchi in high concentration. Fifty thousand units of penicillin in 1 c.c. of distilled water, to which 3 or 4 drops of glycerin are added to stabilize the aerosol, are nebulized every three hours, with a six-hour interval during the sleeping hours. If the penicillin aerosol is to be continued after the epinephrine-fastness has been broken, it is advisable to precede the inhalation of penicillin by the inhalation of a few breaths of 1:100 epinephrine, or 1:200 isuprel, so as to widen the lumen of the lung. Very often, this therapy will have to be prolonged for five to ten days following responsiveness to epinephrine until the patient's bronchial secretions are free of discoloration and are at a minimum. At the same time, penicillin is administered parenterally with daily injections of 300,000 units of prolonged acting penicillin.

Because of the possible toxic effects of streptomycin and dihydrostreptomycin, its routine or combined use with penicillin is initially avoided. It is added only when the sputum remains purulent or in the presence of pencillin-resistant organisms in the sputum. Dihydrostreptomycin, because of its lower incidence of toxic effects, is then given by aerosolization in seven divided doses of 1 c.c. each per twenty-four-hour period in a similar manner as penicillin. The total dose per day ranges from 0.5 gm. to 1.5 gm. Its parenteral use is withheld. In our experience it has rarely been necessary to use streptomycin or dihydrostreptomycin.

As yet we have had no opportunity to use bacitracin aerosol, used successfully by Prigal,[11] and the newer orally administered antibiotics, aureomycin, chloromycetin, and terramycin.

Antihistaminics.—The recently introduced antihistaminic drugs are of little or no value in this condition. In fact, they are contraindicated, as they possess an atropine-like effect in drying up bronchial secretions, and thus aid in producing mucous plugs. Before substituting these medications, the action of which is neither so certain nor so prolonged, it is well to remember that epinephrine and epinephrine-like compounds are the most powerful antihistaminic agents now in use.

In summary, when one is confronted with a patient in status asthmaticus, the danger of death is ever present. The judicious use of the above procedures may be lifesaving.

THE ROENTGEN DIAGNOSIS OF SILICOSIS

EUGENE P. PENDERGRASS, M.D.
Professor of Radiology, University of Pennsylvania
Philadelphia, Pennsylvania

I AM GRATEFUL for the honor and conscious of the responsibility of speaking to you on this occasion, a period dedicated to the memory of Russell D. Carman. This is not the time for me to attempt to refresh your minds concerning Dr. Carman's contributions to medicine. Many of these are a matter of record. Dr. Carman was a physician, scientist and teacher. He possessed such qualities as understanding, honesty, reason and justice, which were a source of inspiration and satisfaction to those of us who were privileged to know him. Honorary lectures such as this provide an opportunity for all to pause and contemplate the achievements of one of our great physicians, an opportunity for us to rededicate our lives to those things that will stimulate our greatest efforts toward improving medicine and through it providing greater service to our fellow man.

The subject which I have chosen for presentation is one of timely interest, although some of the symptoms and changes in the lungs produced by inhalation of dust in certain occupations were described by medical writers many centuries ago.

Our ideas concerning the prevention and control of disease have undergone a remarkable transformation during the past fifty years. The modern doctor, according to the late David Riesman, is no longer being called upon to treat illnesses which have disappeared or are rapidly vanishing. His work is to take on new orientation, that of guardian of the health rather than curer of ills for after all, "to guard is better than to heal; a shield is better than the spear."

Today in this industrial age, as never before, many of the forms of occupational disease fall within the province of the family doctor as well as the industrial physician. Our task is to be aware of the hazards affecting our working people in order that we may help make the industrial population a source of strength and not a source of weakness. We have to insure that as a result of modern industry and commercial procedure and environment, we do not saddle ourselves with a number of disintegrated and therefore unhappy, discontented men and women.

One of the earlier references concerned with dangers of dust exposure is Pliny's[61] description of the devices used by refiners to prevent inhalation of the "fatal dust."

In 1556, Agricola[1] described the perils of mining and the pestilential air breathed by miners. Ramazzini[63] in 1700 called attention to the possible relationship between dust inhalation and consumption. In the Renaissance, physicians and mining engineers were aware that the metal miners suffered from shortness of breath and died prematurely. Anatomists had described "heaps of sand" in the lungs of stonecutters and they called the condition phthisis. Thackrah,[74] in 1831, noted that sandstone workers died before forty, but there was no unusual instance of lung diseases in brick and limestone workers. Although the effect of various dusts in the lungs was recognized previously by other writers, Zenker[84] in 1867 is given credit for having coined the word "pneumonokoniosis." Shortly thereafter, in 1870, Visconti[77] described a pathological condition of the lungs resulting from inhalation of silica which he called "silicosis." In more recent years, numerous studies and investigations have been carried out in many countries. In the United States, the investigations carried on at the Saranac Laboratory under the direction of the late LeRoy U. Gardner[25] have added tremendously to our knowledge of the development of pneumonoconiosis and silicosis in the experimental animal.

Pneumoconiosis

Pneumoconiosis is a broad generic term used to describe all forms of pulmonary reaction to dust lodging within the lungs, with no implication as to character, severity, or effect on function. Certain of these reactions may be demonstrated by a roentgen examination of the chest, but in most instances they are entirely non-specific, are unaccompanied by formation of progressive fibrosis, and are of no clinical significance. In the light

Russell D. Carman Memorial Lecture presented at the annual meeting of the Minnesota State Medical Association, Duluth, Minnesota, June 12, 1950.

of present knowledge, however, we recognize at least two clinically important specific pneumoconioses, namely, silicosis and asbestosis, as well as a number of benign pneumoconioses resulting from the inhalation of a variety of inert but radiopaque dusts. The former may be productive of disability, whereas the latter are of clinical significance only because they may lead to errors in diagnosis through their ability to produce upon the roentgenogram a nodular pattern at times indistinguishable from that occurring in silicosis.

Silicosis

Silicosis is a form of pneumoconiosis which is thought to be due to the specific action upon the lung tissue of chemically free silicon dioxide in finely divided form and which produces changes that can be demonstrated in many instances on a roentgenogram. It is probable that all dusts, with the exception of chrome, free silica and certain silicates, produce very few changes in the lung that can be recognized with assurance on the roentgenogram.

In order to produce lung changes it is necessary for the silica dust to reach the lung alveoli, to get into the interstitial tissues either through the agency of macrophages (dust cells) or by way of alveolar pores, and to be deposited in sufficient concentration at some spot where either through its inherent physicochemical properties or together with some other factor or factors, as yet unknown, an abnormal amount of fibrous tissue formation may be stimulated.

In the early days, the tissue reaction to quartz dust was considered to be due to the sharp-pointed particles. This concept was invalidated when diamond dust and carborundum were shown to be benign. Then came the solubility theory of silicosis. This concept considers silica as slightly soluble, which in turn stimulates the formation of fibrous tissue. Although this theory has served as an excellent working hypothesis, several inconsistencies have been pointed out by Evans and Kascht.[20] These include:

1. A local concentration of ions, or a dissolution of the dust deposit has not been demonstrated.
2. Several benign silicates supply a greater number of soluble ions to the local tissue than does quartz.
3. There does not appear to be a constant relationship between solubility and the degree of fibrous tissue formation.
4. Silica in solution in the tissues would be precipitated as sodium silicate, which is benign.
5. It would appear that a fibrotic nodule would offer little functional defense to a substance in solution, as diffusion would progress through such a barrier.

In view of the above objections, Evans and Kascht[20] recently have examined various substances commonly responsible for the production of the pneumoconioses. They failed to find anything in the nature of a common chemical or physical property, such as solubility, hardness, sharpness, or known chemical reactivity, in the tissues that could explain the production of the characteristic fibrotic nodule. They found that the dusts known to produce fibrosis were composed of substances whose most stable form was that of an asymmetric crystal, and therefore, potentially piezoelectric. The benign dusts were either amorphous or of crystalline classes which are not piezoelectric.

Piezoelectricity is defined as being that property possessed by certain asymmetric crystals which allows a transformation of energy, in either direction, mechanical and electrical energy, Evans and Kascht.[20] If such a crystal is distorted by pressure, an electric polarity is produced, and conversely, if such a crystal is placed in the proper electric field, a distortion of the crystal surfaces is produced. There may be many related secondary effects. Evans and his associates have carried out a number of experiments which seem to support the thesis that asymmetric crystalline crystals under certain circumstances produce fibrosis.

Although many problems present themselves for future clarification, Evans and his co-workers,[19,21,22] have shown the following:

1. The ability of foreign materials to produce fibrogenesis is correlated with their crystalline structure.
2. Those tested amorphous materials and materials whose crystalline state possesses a central point of molecular symmetry (symmetrical crystals) are nonfibrogenic.
3. Those tested crystals which do not possess a central point of symmetry (asymmetrical crystals) and possess piezoelectric properties are fibrogenic.
4. Several materials previously untested bio-

logically, selected for their physical properties, were tested and shown to be fibrogenic.

5. Fibrous tissue reactions are considered to be stimulated by releases of energy in mechanical or electrical states within tissue.

Parmeggiani,[51] in 1947, writing on the same subject states that since silica nodules also are formed in organs free from any mechanical activity, such as the spleen, liver, and lymphatic glands, it is not possible to explain the tissue damage by piezoelectric action due to pressure on the crystals.

I am not well enough informed about the biological effect of piezoelectricity on tissues to have an opinion as to whether the theory being tested by Evans and his co-workers is correct, but I enthusiastically believe that their investigations should be encouraged and supported. If their present concepts prove to be right, many of the baffling problems concerned with the control of silicosis may be explained and some of them solved.

Pathogenesis

Although it cannot be stated with certainty whether the effect theory is responsible for the tissue responses in silicosis, chronic pulmonary disease of the type under consideration is dependent upon an adequate concentration of dust exposure maintained for a sufficient period of time. The rate of development will be influenced by the adequacy of the drainage system of the lung.

The process by which the phagocytes and macrophages carry off the dust particles has been well described by Gardner[30,32] and others.

Inhaled dust first exerts its influence on living cells primarily within the bodies of the alveolar phagocytes, and it is here that fundamental differences due to the physicochemical composition of the irritant become evident. Inert substances, in which category the great majority of dusts belong, provoke no structural changes within the cells. In contradistinction, free silica exerts a specific effect. Degenerative changes, easily confused with those in the "epithelioid" cells of tuberculosis, quickly become evident. The enlarged cells contain visible lipoid. Their nuclei repeatedly divide, and giant cells comparable to the Langhans' giant cells of tuberculosis are formed. Eventually these migrating phagocytes concentrate the silica in and about the pulmonary lymphatics, where the toxic particles, either directly or indirectly stimulate connective-tissue proliferation, with the resultant formation of microscopic silicotic nodules situated in the immediate vicinity of the lymphatic trunks.

At this stage the only general influence of the disease thus far discovered is the increased likelihood that the more advanced changes of silicosis will result from the continued inhalation of silica-laden dust. After sufficient reaction has developed in the lymphoid tissues, the flow of lymph is retarded. The alveolar phagocytes, however, continue to take up fresh particles of dust but, due to their apparent inability to enter the lymphatic vessels, collect upon the walls of the air spaces proper. Once again, the silica exerts its specific effect, causing proliferation of connective tissue and the formation of parenchymal silicotic nodules. Microscopically the nodules are seen to be composed of hyaline collagen fibers and are evenly distributed throughout the lungs (Gardner.[32]) Such, in brief, is the pathology of simple silicosis.

Tissue reactions occur along the lymphatics accompanying the pulmonary vessels and bronchi, within the interstitial tissues and along the pleura.

From an examination of the mineral particles which have gained access to the lung it seems that the protective mechanisms of the respiratory tract exclude most of the particular material greater than 10 microns in diameter. Likewise it is accepted generally that the smaller silica particles, 0.5 to 2.5 microns in size, are more likely to produce lung damage than are the larger particles. It is believed by some investigators that certain dusts (diluents or contaminating dusts) may have modifying effects upon the action of free silica in the lung tissues; for instance, carborundum and aluminum oxide may retard and alkaline soap powders may accelerate the usual reaction to free silica. There is some uncertainty about this hypothesis, however, as Gardner[30] says that "definite proof of accelerators to the action of silica is yet lacking; it has been suggested that cases of 'rapid silicosis' in human beings may be due to excessive exposures to silica or unusual fineness with or without associated infection." It is evident, therefore, that in order to evaluate a dust hazard one must have a knowledge of the behavior of the dust in the course of its production and while it is suspended in the air, and its behavior in the respiratory system, as well as an understanding of its specific action in the lung tissue (Hatch.[37]) *The knowledge that a workman is exposed to dust released in the processing of a material containing free silicon dioxide is insufficient evidence in itself to justify one in stating that the atmosphere at the breathing level contains harmful quantities of free silica dust.*

The reasons for this observation are supported by ventilation and sanitary engineers familiar with many of the differences in the behavior of dusts and some of the factors concerned may be abstracted as follows:[37]

1. The composition of the air borne dust may differ from that of the parent material.
2. The composition of the dust retained in the deeper portions of the lung may differ from that of the air borne dust.
3. The amount of dust retained in the respiratory system and the relative amounts retained in the upper portion of the tract and that found in the alveoli vary with different dusts.
4. The particle size of the alveoli dust differs from that of the air borne material.
5. The flocculating properties of dust vary and this affects the retention in the respiratory tract, its penetration to the alveoli, and the behavior of phagocytes toward the dust.
6. The rate of phagocytosis varies from one dust to another.
7. The toxicity of silica is apparently reduced in the presence of certain other materials.

According to Hatch[37] the relative significance of these several aspects of dust behavior is not fully understood but their importance has been demonstrated both in the laboratory and in industrial experience.

The modifications occurring from the inhalation of dusts containing mixtures of free silica and other minerals may be quickly passed. The primary pathology is the same, the essential differences being simply the result of co-existing silicosis and a benign pneumoconiosis, each of which alters to some extent the appearance of the other. It should be recalled, however, that some inert dusts, when mixed with free silica, cause varying degrees of retardation in the development of the silicotic process. At this time the use of aluminum deserves brief but special mention. Denny, Robson, and Irwin[14] were the first to announce the specific inhibitory effect of aluminum. Their animal experiments and those of others,[33] some of which were conducted simultaneously in another laboratory, have demonstrated conclusively that metallic aluminum and aluminum hydrate, when given by inhalation, will prevent the fibrous reaction to quartz. The possible clinical applications of such a discovery are obvious, and have already stimulated considerable investigative work from the standpoint both of prophylaxis and of therapeusis. While a complete discussion of their present status is beyond the scope of this paper, it may be said that further evaluation is required and that aluminum therapy should in no circumstances be applied as a substitute for other and already recognized methods of dust control.

As evidence of the necessity for caution, are the lung changes associated with the manufacture of alumina abrasives reported by Shaver,[72] and the experimental observations of Evans and Zeit[21] on aluminum phosphate.

The alteration of the silicotic process when complicated by the presence of infection is not nearly so simple.[58] The increased susceptibility to tuberculosis in man recorded by Merewether,[48] and proved by the classic animal experiments of Gardner,[25,28] needs no recapitulation. Two facts, however, must again be emphasized: (1) that it is the presence of associated infection which accounts for most of the disability arising from silicosis, and (2) that infection, when it occurs, may manifest itself in either of two ways, namely, by the development of tuberculo-silicosis or of silicosis with tuberculosis.

Tuberculo-silicosis is common and according to Brumfiel and Gardner,[6] whose observations are adequately substantiated both clinically and pathologically, it is "a distinct disease entity with certain characteristics peculiarly its own, in that it is neither silicosis nor tuberculosis nor is it a simple summation of the two." It is the result of the interaction of tubercle bacilli and silica in the same area, with the resultant formation of tuberculous granulation tissue together with a modified type of silicotic reaction. Pathologically, it is characterized by the formation of slowly developing, well defined, hard or rubber-like areas of massive conglomerate fibrosis surrounded by a marked degree of emphysema. On microscopic section, nodules are found embedded within dense hyaline fibrous tissue which virtually obliterates the normal pulmonary structures. The tuberculous component of the process sometimes is identified easily by the presence of widespread caseation, but not infrequently it is only after painstaking search that isolated, non-caseous tubercles or occasional clumps of acid-fast bacilli are discovered.

Silicosis with tuberculosis, by comparison to tuberculo-silicosis, is rare, but it does occur in one of two forms: either (1) as the result of infection superimposed upon a progressive and still active silicosis or (2) as the result of infection superimposed upon an old and already stabilized silicotic process.

In the first instance the infection becomes acute, and its course is usually one of uncontrollable extension. In the second, tuberculosis develops upon a background of an already stabilized silicosis in which the quartz particles are presumably completely isolated within their fibrous nodules and thus exert no effect upon the superimposed infection. We have then simply the coexistence of silicosis and tuberculosis within the same individual, but without modification or acceleration of either disease process by the other.

The effect of silicosis upon non-tuberculous infection is less well documented. It cannot be denied with finality that non-specific inflammatory reactions within silicotic lungs occasionally may be the precursors of conglomerate areas of fibrosis. Proof, however, is lacking, and the meager available evidence is opposed to such an assumption. Pierpont[60] has demonstrated that in his iron-mining area the incidence of pneumonia is no greater than in the general population, and that the behavior of the disease when it does occur is unaltered by an underlying silicosis. Similarly in rabbits it has been shown that silicosis exerts no effect upon their susceptibility to infection with Type III pneumococcus.[78]

On the other hand, Gardner,[32] after microscopic examination, was able to discover in only 60 per cent of cases showing massive conglomerate fibrosis, indisputable evidence of tuberculous infection. Perhaps in most if not all of the remainder, the silicotic fibrosis had obscured the tuberculous component of the process, and it was his feeling that an underlying tuberculosis was the etiologic factor accounting for at least the majority of massive fibrous lesions.

Roentgen Considerations[55]

It is generally conceded that the roentgenographic examination, properly done, is the most precise method at our command for demonstrating pathological changes produced by pneumoconiosis or silicosis in the living individual. There are, however, many other conditions that produce shadows in the roentgenogram which may simulate some of the various shadows found in pneumoconiosis.[54] In order to evaluate correctly the various shadows observed in a roentgen study of the chest, it is necessary for one to possess some knowledge and experience concerning such an examination, and certain information about the patient being studied. Some of the more important requirements may be enumerated as follows:

1. A knowledge of the anatomy of the chest and some of the physiological manifestations of the various structures contained therein; an understanding of the histology of the lungs and of their lymphatic system.
2. A thorough familiarity with roentgenoscopic and roentgenographic appearances of the normal structures of the chest and their permissible variations.
3. A clear perception of the pathology of pneumoconiosis and of lesions that give a somewhat similar roentgenographic appearance.
4. Some knowledge of the history of the individual, especially the occupational record and familiarity with the physical signs in the particular patient.
5. Some information concerning the industrial process that is responsible for the production of the dust. Dust counts at breathing levels and chemical analyses of the dust are exceedingly important when available.

If all of the above information is available, one should be able to render a diagnosis which although presumptive is likely to be correct in the majority of instances. Very often, however, one gives an opinion on insufficient data and in so doing referring physicians become confused and injustices occur.

I have always regarded the roentgen examination as a consultation, and used as such it is likely to be more valuable. An ideal program for the diagnosis of pneumoconiosis in the living would include a study by a group, the members of which would be a general physician, a rhinologist, a bronchologist, a clinical pathologist, a specialist in tuberculosis, a physiologist interested in pulmonary function, an engineer expert in industrial hygiene and a general roentgenologist. Such a program is ambitious. Thus, in the majority of instances the referring physician tells the individual that he has pneumoconiosis or silicosis on the basis of a history of dust exposure, a physical examination which is thought to exclude other conditions that might produce similar symptoms, and the presence of abnormal shadows in roentgenograms of the chest which are compatible with those found in pneumoconiosis. The fact that diagnoses are made in this manner places a tremendous responsibility on the roentgenologist, for he must not only describe the roentgen appearances, but after he has done so, he must correlate other information which has been supplied to him with the roentgen observations, and arrive at a tentative or presumptive diagnosis. This is a safe procedure if we, as radiologists, fulfill our obligations to the referring physician and patient.

Criteria for Diagnosis[58]

The diagnosis of silicosis rests primarily upon a positive history of sufficient exposure to free silica dust plus the roentgenologic demonstration of characteristic deviations from the normal within the lungs. Physical and laboratory examinations are then required to exclude other conditions producing similar roentgenographic changes. Once the diagnosis is established, physical examination is required to determine the general physiological effect of the pulmonary condition and to determine whether any disability has resulted therefrom. Differences in individual incentive to work, the natural retardation of physiological responses with advancing age, and the accrued evidence to show that ordinary, slowly developing, simple silicosis is usually in itself nonproductive of a diminution in ventilatory capacity, all combine to make an accurate estimate of the latter an extremely difficult problem.

Machle,[44] however, has shown that the inhalation of the more active dusts results in certain changes in the behavior of the lung which favor retention of the very fine particles in larger numbers than would be expected to occur on a theoretical basis alone. The change is one of bronchiolar constriction, which leads to reduction in pulmonary volume and if continued leads to stasis with its attendant pathological changes. This is the type of observation which we hope to learn more about from pulmonary function studies.

Classification

Before discussing the roentgenographic appearances, it is necessary to say a few words about classification of silicosis as observed in the roentgenographic studies. There are many different ones in use. The most recent has been described by Fletcher[24] and his associates, who state that it may be necessary to have systems of classification for the various types of pneumoconiosis in men exposed to different dusts in various industrial processes. We have given the subject of classification or roentgen appearances considerable thought and feel that any classification used should not place too much emphasis on the roentgen observations, except in those instances in which there is good evidence of infection complicating the silicosis. A simple classification that has worked well for us for the last ten years is: *simple silicosis* and *silicosis with infection. It should be borne in mind that one cannot from a study of the chest by present roentgen methods give any reliable opinion as to the extent of disability.*

Simple Silicosis

The characteristic lesion in silicosis is a circumscribed nodule of hyaline fibrosis. The earliest lesions are invisible or are recognizable only microscopically or with a magnifying glass.[30] They are deposited along or within the lymph channels where they may impede lymphatic flow.[26,79] Gardner[32] states that when the lymph flow is retarded the phagocytes do not enter the lymphatics but collect here and there over the walls of the air sacs. Parenchymatous nodules may then develop which ultimately reach a size of 3 to 4 mm. in diameter. Pathologically, the nodules have well defined borders except when there are accumulations of non-siliceous dusts.

The earliest roentgen lesion that I accept as evidence of simple silicosis is the small, discrete, multiple shadow, 2-6 mm. in diameter, which is more or less uniform in size and density and does not disappear in a roentgenogram made with slight rotation. *Shadows that disappear with slight rotation are likely to be vascular.* The blood vessel shadows are denser and their borders are more sharply defined than are those of nodules. The shadows of the silicotic nodules are usually distributed along the vascular channels and the bronchial tree of both lungs, and at times they may be limited largely to one lobe. Not infrequently, even though a bilateral distribution of the shadows occurs, one does not see them in the apical, peripheral and lower portions of the lung fields.

The roentgen appearance of the shadows of the silicotic nodules are not as characteristic as one would wish. Some are round, some oval, some irregular, some large and some small. Most of the lesions have a uniform density, but some have shadow densities in their centers simulating that produced by calcium. The shadows of these lesions are called nodulation, which unwittingly implies that they can be distinguished from mottling due to tuberculosis or some other infectious process. I frequently have found that the periphery of the nodular shadows (silicotic) is so ill defined that in itself it cannot be differentiated from mottling in miliary and other types of tuberculosis and small shadows due to a generalized metastatic malignancy. In most instances, however, a correct diagnosis can usually be arrived at by correlating the roentgen findings with the history and clinical data.

One of the interesting questions that arises concerning the silicotic individuals as seen by the roentgenologist is that not all of them develop generalized nodulation that can be seen on the roentgenogram. This apparently is true even when individuals are working under similar conditions in the same industry, and up to the present time, no adequate explanation has been made.

When nodulation occurs, the nodules may or may not show progressive changes. In a few patients who have been followed for fifteen years, we have observed the pattern of nodulation replaced by massive shadows with either complete or almost complete disappearance of visible nodular shadows on the roentgenogram. Just how often this occurs will be determined only after years of serial studies.

I have always been interested in whether nodulation is more likely to develop in the younger or the older individual. This question is likely to be answered as more experience with serial studies is obtained. My observations in one industry (almost pure silica) over a period of fifteen years tends to show that nodulation does occur more frequently in the young individual. These nodules have been observed in individuals who have had a silica dust exposure of five to ten years. One wonders whether the nodulation seen in some of the older individuals who have worked for longer periods may likewise have developed during the five to ten years' exposure period and in certain instances failed to progress.

Generalized nodulation is often present with very little, if any, clinical evidence of disability. Such an observation is extremely important to keep in mind for it will help to prevent such individuals from being thrown out of work and placed on compensation. Experience with such individuals has shown that if they are allowed to continue to work in a healthy atmosphere, the lesion may not progress, no unusual disability develops, and a family catastrophe or hardship due to loss of adequate compensation and unhappiness is prevented.

These nodules, uniformly distributed throughout the pulmonary parenchyma, form a characteristic shadow pattern, and *the demonstration upon the roentgenogram of this generalized nodulation is, from the radiologist's point of view, fundamental to the diagnosis.* There may or may not be associated enlargement of the hilar lymph nodes, despite the fact that it is in the lymphatic tissues that the earliest silicotic nodules have been shown to develop. These early nodules, however, by their very fibrous nature, are destined to cause eventual contraction, and in cases of slowly developing silicosis it may no longer be possible to demonstrate hilar lymph node enlargement by the time the parenchymal nodules are grossly visible.

Another lesion generally included under the classification of simple silicosis is the small conglomerate lesion. Such lesions may result from a combination or coalescence of discrete nodules or the lesion may occur as such primarily.

Conglomerate lesions are usually localized and do not occur in the same portion of the lung in every individual. On the other hand, roentgenographic studies of individuals with such lesions more frequently show them in the upper half of the lung fields. Microscopic examination[32] of the tissues from such areas oftentimes reveals no evidence of infection. The nodules seem to be closer together than in other portions of the lung; they are less uniform in size, and they are embedded in a matrix of diffuse, fibrous tissue having the same characteristic appearance as that forming the nodules themselves. It is possible that the conglomeration may have occurred because the portion of the lung in question was previously damaged by a localized, inflammatory process occurring before or during the early period of the dust exposure.[32] More dust would tend to accumulate in such an area and possibly the nodules would develop irregularly and closer together. Another explanation is that the scar contraction of the silicotic process may be sufficient to produce the conglomerate lesion.

The shadow of the conglomerate lesion in simple silicosis is often difficult to distinguish from that found in silicosis with infection. From the roentgenological standpoint they may be impossible to differentiate in a single examination, whereas serial examinations may or may not show slight changes in the extent of the shadows of lesions that are complicated by an active infection.

The roentgen observations in *simple silicosis* may be summarized as follows:

Trachea: Its shadow is in a normal position.

Heart and aorta: Their shadows are not noticeably affected by the silicotic process.

Domes of the diaphragm: The shadow and movement of the domes of the diaphragm are not affected by the silicotic process unless a coincident emphysema is present.

Hila: The shadows of these structures are as a rule not noticeably changed.

Trunk shadows and linear markings: Slight to moderate variations in these shadows are diffiocult to evaluate.

Lung changes, nodulation and conglomerate lesions: The shadows of *nodulation* (2 to 6 mm. in size) are usually bilateral in distribution. Variations may occur such as a lobar or unilateral distribution.

Shadows of nodules may be difficult to differentiate from those occurring in some types of tuberculosis, metastatic malignancy and fungus infestations, et cetera.[54]

Conglomerate lesions: These shadows are usually found in the upper half of the lung fields and are difficult to evaluate in single examinations. Superimposed metastatic malignancy and lesions due to an active infection may produce similar appearances.

Hyperventilation and emphysema: Such conditions may be present and demonstrable by the roentgen examination. Their evaluation, as to cause and effect from dust exposure, however, is more difficult and does not fall within the province of the roentgenologist.

Silicosis With Infection

In this group are included all cases of silicosis with detectable evidence of infection. It is not always possible in the living patient to determine whether the infection is active or inactive even in instances when conventional clinical and laboratory examinations are available. Under such circumstances, mistakes will occur, but if one exercises good judgment, the affected individual can be protected by taking the necessary precautions.

The lesions (either some or all) that have been described as occurring in simple silicosis may be modified by infection. Other lesions that may be found include cavities (usually thick walled) tuberculous in origin, cavities occurring as a result of necrosis of anemic infarcts, massive lesions, mottling, soft nodulation, various degrees of emphysema and bleb formation, pleural thickening, pleural collections, pneumothoraces and deformations of the domes of the diaphragm. The roentgenologist is rarely able to predict whether the infection is due to the tubercle bacillus or some other organism. One suspects, however, that in the majority of instances, the super-imposed infection is tuberculosis, for Gardner[32] states that the postmortem examinations showed an element of tuberculosis in 60 per cent of the cases.

The changes occurring in the various structures of the respiratory and cardiovascular tracts as demonstrated by the roentgen examination may be summarized as follows:

Trachea.—Its shadow may be in a normal position, especially if a tuberculous process or some other infection is superimposed upon an already established silicotic process. In some instances the trachea is found displaced to one side. At such times, it is my feeling that the silicotic process has occurred either simultaneously with tuberculosis, or the tuberculous lesion was probably established before the silicotic changes became manifest, or the traction of the fibrotic changes produced by a tuberculous and silicotic lesion one side was greater than that of the silicotic process of the opposite side.

Heart and Aorta.—In some instances evidence of cor pulmonale is observed in the advanced silicotic individual. Some clinicians[17] have regarded this condition as a complication of silicosis. The relation between cause and effect is difficult to establish in this instance and cardiologists who have given thought to the question find themselves unable to express an opinion. Many of us who have been interested in silicosis for years, have not been impressed with the incidence of cardiac complications. On the other hand, it is possible that with increased use of the electrocardiograph in the well advanced silicotic, more evidence of slight heart changes may be found. But even if such evidence is found, it is well known to the cardiologist and the general pathologist that in the older age group not exposed to harmful dust, which come to autopsy, cardiac complications are not uncommon. Even in the advanced silicotic with well established emphysema, Gardner[32] states that "hypertrophy of the right side of the heart without arteriosclerosis and even greater involvement of the opposite side is a rarity."

Occasionally, the heart and aorta are displaced to one side or backward by the contracting scar of a tuberculous infection and silicotic process. As in the case of the trachea and in the absence of data to the contrary, such displacement is thought to occur for the same reasons.

Domes of the Diaphragm.—If considerable emphysema is present, the domes of the diaphragm may be depressed and limited in their movements. At times it is necessary to have the patient cough in order to demonstrate, roentgenoscopically, evidence of diaphragmatic excursion.

Individualization of the costal components of the domes of the diaphragm is quite marked when there is considerable basal emphysema.

Another abnormal appearance is multiple peaking of the domes of the diaphragm. It may be impossible to differentiate the peaking caused by pleural adhesions from that due to inelasticity of certain structures of the lung. Both conditions may be present.

Hila.—The shadows of the hila may or may not be within normal limits. The hilum shadow may be enlarged or its shadow may be partly or totally obscured by a larger shadow produced by a lung lesion. The hilum may be displaced upward, laterally or backward by a contracting scar of a silicotic process plus an infection (similar to that causing displacement of the trachea).

Lung Changes.—Mottling is a term that is applied to the small and poorly defined shadows produced by an acute or chronic infection. The roentgen manifestations of mottling and nodulation may be identical and exceedingly difficult or impossible to differentiate. The shadows of mottling often lack a uniformity of distribution and are more likely to change in form in subsequent examinations than are the shadows of nodules. Mottling usually occurs as a result of a bronchogenic spread of a tuberculous lesion or the result of a fungus infestation.

Soft Nodulation.—The shadows of soft nodulation are much larger than those produced by nodulation and mottling, but are smaller than the conglomerate shadow. The description of such a roentgenologic shadow is provided in order to emphasize a perinodular cellular reaction that is observed by the pathologist. These shadows are much more likely to change in character in subsequent examinations than in the shadow produced by nodules, and change less than those due to mottling.

Nodulation.—The shadows of nodulation are similar to those described under "simple silicosis." Soft nodulation and nodulation cannot be demonstrated by a roentgen examination in every case of modified silicosis with infection. This is particularly true in certain industries such as hard coal mining and granite cutting. In cases where there is only roentgen evidence of massive or conglomerate shadows one is more likely to make errors in interpretation.

Massive Shadows.—These shadows vary from 3 to 20 cm. in size. Some are round, some oval and some wedge shaped. These lesions are usually due to extensive areas of fibrosis and are found in the upper third or upper two-thirds of the lung field. Occasionally it is possible with overexposed films, body section roentgenograms or a Potter-Bucky roentgenogram to show some of the details of a massive lesion, such as distorted and obliterated bronchi, cavities and areas of calcification and caseation.

A few years ago, most of these lesions were thought to be due to silicosis with infection. Riddell,[65] Gardner,[32] McCloskey[45] and others question whether this is always true. Gardner[32] thinks that a "third essential factor may be minerals other than free silica."

From a rontgenologic standpoint, I have attempted to determine whether the massive lesion extended to the periphery of the involved lobe of the lung and have used this information as evidence for or against the presence of an active infection. For instance, if a lesion extends to the interlobar fissure or the thoracic wall, such a lesion would be regarded as the seat of an active infection. If the massive lesion were situated in the center of the affected lobe, the roentgen evidence would not necessarily be in favor of an active infection. I realize that such deductions by themselves are of very little value, but in the absence of more convincing clinical and pathological proof attention to this detail may prove to be helpful.

The massive lesions do not tend to displace the midline structures (trachea, hila, heart and aorta) by scar contraction. When displacements of those structures occur, the lesion which produces them is more likely to be either a tuberculous or Friedländer baccillus infection which has preceded or occurred simultaneously with the silicotic process. It should be possible however, for the contracting scar of a tuberculo-silicotic process of one lung to overcome that of an uncomplicated silicotic process on the opposite side.

Occasionally, one sees a lesion which by roentgen methods is diagnosed as a massive lesion, which at autopsy turns out to be a necrotic, anemic infarct or a cavity in which there is no microscopic evidence of infection and which is filled with a syrup-like material. I know of no way to diagnose the true nature of these lesions by the roentgen examination.

We have observed a migration of massive lesions toward the hilum in certain instances. This observation has been very helpful, and explains the prominent shadows adjacent in certain patients in whom there are large masses simulating greatly enlarged hilum lymphnodes.

The rationale for further division into the subgroups tuberculo-silicosis and silicosis with tuberculosis has already been explored, with emphasis placed upon the concept that tuberculo-silicosis is a separate and distinct, chronic disease entity resulting from the prolonged interaction of two disease processes, but differing radically in its behavior from either occurring alone.

The roentgen manifestations of tuberculo-silicosis are protean and yet distinctive. Early in its evolution there are characteristically present linear strands of fibrosis, presumably the result of previous infection, which however may be so fine as to be almost or completely obscured by the accompanying nodulation. In due course, serial roentgenograms reveal evidence first of concentration and later of coalescence of the nodulation about these foci of fibrosis. Newly developed areas of coalescence may extend to the pleural surface of the lungs, but if the disease remains chronic they inevitably contract to form the dense, well delineated "massive shadows" or areas of conglomerate fibrosis so typical of tuberculo-silicosis. These are located most often in the upper lung fields, but may radiate outward from the region of the hilum, occur as rounded masses deep within the lungs, or appear as wedges with their bases directed peripherally. Commonly, these areas of conglomerate fibrosis continue over the years to increase slowly in size, incorporating within themselves more and more of the individual silicotic nodules from other portions of the lungs, until finally one may have as the end-result either single or multiple, unilateral or bilateral massive shadows of conglomerate fibrosis. These may be so extensive as to destroy completely the ordinary identifying characteristics of both the tuberculosis and the silicosis, and they are invariably productive of an advanced degree of surrounding pulmonary emphysema. Since the affected individuals are not toxic, it is this latter which accounts for their obvious and often high degree of disability.

Only rarely is one sufficiently fortunate to see the evolution of the entire process in a given individual. It would seem however, that the pathologic evidence is sufficient, and that adequate numbers of cases have now been followed by means of serial roentgenograms over a period of years, to warrant a presumptive diagnosis of tuberculo-silicosis either upon the visualization of nodulation with concentration, coalescence or conglomeration, or, when bilateral, upon the demonstration by themselves of large areas of conglomerate fibrosis. Limited reservation must of necessity be entertained, however, until the case for or against non-tuberculous infection as the etiologic agent in the production of conglomerate fibrosis is definitely proved.

The behavior of many cases of tuberculo-silicosis would make it appear that the tuberculous component of the process is for a time held in check by the surrounding fibrosis. It remains a potential source of danger, however, and may become active at any time. Such activity manifests itself on the roentgenogram by the development of mottling and, once established, alters, by acceleration of the fatal outcome, the entire course of the disease. It is still true, therefore, that a high percentage (though by no means all) of persons with tuberculo-silicosis ultimately die of tuberculosis.

Silicosis with tuberculosis, as previously indicated, may occur in either one or two forms, the clinical course and roentgen behavior of which are as distinctively different as is their pathology. Early in their development they may present an extremely difficult problem in diagnosis because of one's inability, except upon the basis of preceding serial roentgenograms, to formulate any estimate of the activity of the underlying silicotic process. In both groups the infectious component is first identified by the presence on the roentgenogram of single or multiple, usually apical, ill-defined areas of infiltration or mottling, superimposed upon a background of discrete nodulation. The subsequent behavior, however, is radically different.

In the first group—those in which we have fresh infection, either new or arising from the reactivation of a latent focus, superimposed upon a progressive and still active silicosis—the quartz is incompletely encapsulated by the still immature silicotic fibrosis and retains its ability to exert its specific effect. When the silica concentration is high, tiny foci of necrosis within the nodules occur, providing an ideal medium for the growth of tubercle bacilli; but even when the silica content is not excessive there is in some occult manner produced an environment eminently favorable to their multiplication.[28] Serial roentgenograms exhibit new areas of mottling and local extension of the original foci, about which the silicotic nodules may become extremely abundant.[29] In some, the so-called "perinodular type," there occurs, probably as a result of massive superinfection, a rapid enlargement with loss of definition of each nodule throughout both lungs, due to the development of an intense surrounding zone of collateral inflammatory reaction. Minute foci of caseation are usually present, and cavitation does occur, but by comparison with the general evolution of the process it is a relatively late phenomenon. While, rarely, several years may elapse before toxic symptoms supervene, the general tendency is toward uncontrollable extension to death before there is opportunity for the chronic changes of tuberculo-silicosis to occur.

In the second group are the unusual but existent cases in which silicosis and tuberculosis occur together but act independently. As previously indicated, it is presumed that in these cases the silicosis has healed with the formation of such densely fibrous nodules that the quartz is completely walled off and thus cannot exert its peculiar effect upon the superimposed tuberculous infection. The infection, observed by means of serial roentgenograms, is seen to behave typically as it does in non-silicotic subjects.

(To be concluded in the November issue.)

PAN-PACIFIC SURGICAL ASSOCIATION

The Fifth Congress of the Pan-Pacific Surgical Association will be held in Honolulu, November 10-21, 1951.

The object of the Pan-Pacific Surgical Association is to bring together surgeons from countries bordering on the Pacific Ocean so as to permit the exchange of surgical ideas and methods and to develop a spirit of good fellowship among the various races represented. Although it was planned that meetings would be held every three years, world events have permitted but four conferences since the organization was conceived—the first in 1929 and the last in 1948.

The Fifth Congress provides an opportunity for doctors to combine a delightful vacation in Hawaii with attendance at a scientific meeting, the program of which will be presented by topflight surgeons from the Pacific area countries, as planned by the program committee. Doctors are urged to bring their families with them and are promised luxurious accommodations.

Dr. F. J. Pinkerton, president of the Association, has been officially appointed as travel agent for those coming to the meeting. To be assured of preferred accommodations, travel and hotel reservations should be made through Dr. Pinkerton.

Further information may be obtained by writing the Pan-Pacific Surgical Association office, Suite 7, Young Building, Honolulu, T. H.

THE PREDICTION AND PREVENTION OF CORONARY THROMBOSIS IN THE YOUNGER AGE GROUPS

A Suggestion for Further Study

R. L. PARSONS, M.D.
Monterey, Minnesota
and
J. J. HEIMARK, M.D.
Fairmont, Minnesota

A NEIGHBORING doctor dies at thirty-seven from coronary heart disease; a farmer has a coronary infarction at thirty-four; a buttermaker has a coronary heart attack at forty-eight; the editor of a daily newspaper has a fatal attack at fifty-two. A World War veteran suffers an infarction at 53; another farmer, the same at fifty-two—all proven cases. These are by no means isolated instances but are selected at random from our small community within a short period of time.

We are not concerned here with coronary deaths among the aged or prematurely diseased. Those we may leave to their proper study in geriatrics. We are interested in the factors that produce coronary incapacity, causing such a high mortality in people in the fourth, fifth and sixth decades of life.

The purpose of this paper is to suggest a possible method of predicting coronary catastrophes and of possible prophylaxis for those people who are in their most productive years and who should be of most value to society.

The factors causing a coronary complex in the people in these earlier decades differ markedly from those in the aged. In older people, the primary cause of this trouble is an extensive intimal damage in the coronary arterial tree. Secondary factors are sedentary life, improper diet, and probably disease. In the younger years this initial damage is usually only moderate to minor. Several other factors apparently combine in varying importance to cause an infarction. Among these are prolonged nervous tension, the prothrombin time level, diet, and smoking. It is generally conceded that coronary constriction from chronic over-stimulation due to high nervous tension, worry, and overwork plays an important rôle in the foregoing disease entity. Therefore, we shall not add further comment. However, it is different with the other factors mentioned.

In the patients with coronary heart disease whom we have observed, we have been impressed by the low prothrombin time uniformly present.

TABLE I. PROTHROMBIN TIME BEFORE AND AFTER MIXED MEAL

Name	Approx. Age	Before Meal (Seconds)	After Meal (1 Hour) (Seconds)
G.P.	24	60*	55
A.G.	55	75†	60
S.L.	22	90†	75
B.J.	19	70*	65
A.R.	24	70†	60

*Light meal
†Moderate to heavy meal

TABLE II. PROTHROMBIN TIME BEFORE AND AFTER ALL-VEGETABLE MEAL

Name	Approx. Age	Before Meal (Seconds)	After Meal (Seconds)
B.J.	19	55	45
A.G.	55	45	45
S.L.	24	45	40
L.K.	22	50	45
A.R.	24	45	50

TABLE III. PROTHROMBIN TIME BEFORE AND AFTER SMOKING

Name	Approx. Age	Fasting 7 a.m. No Liquids (Seconds)	Fasting ½ Hour After smoking 2 Cigarettes (Seconds)
B.J.	19	60	45
C.T.	40	70	60
J.C.	40	45	35
G.A.	45	65	50
A.R.	24	60	45

Likewise, we have been impressed by the fairly prompt relief of pain in the non-fatal cases when the prothrombin time has been quickly elevated by the use of the anti-coagulants, heparin and dicumarol. We also noted that the pain did not often recur if the prothrombin time level was sustained at a sufficient height. Pain, however, was most likely to recur following a meal. Knowing of no explanation for this, we ran a short series of prothrombin time levels (Smith bedside whole blood method) on normal individuals immediately before eating and again an hour afterwards. The results are shown in Table I.

As a variation, we also ran a series before and after an all-vegetable meal (Table II).

These tests suggest diet as an important factor in precipitating the coronary syndrome.

THE HEART IN FRIEDREICH'S ATAXIA

M. EUGENE FLIPSE, M.D., THOMAS J. DRY, M.B., and HENRY W. WOLTMAN, M.D.
Rochester, Minnesota

FATTY infiltration of the heart was noted by Friedreich in the original description of the disease that still bears his name. This was in 1863. The hearts in which he noted these changes, however, were those of patients who had died of typhoid fever, and there is no way of knowing whether the changes which were noted were due to Freidreich's ataxia or to typhoid fever. The occurrence of cardiac failure as a terminal event in this disease was emphasized by Pitt as early as 1886. From this time on, scant reference[8,9] was made to the cardiac manifestations of Friedreich's ataxia until the report by Loiseau in 1938. He reviewed the literature and found reports of 40 cases in which there were cardiac abnormalities. It was his belief that these cardiac abnormalities were incidental in some cases and specific to the disease in others.

In 1942, Evans and Wright reviewed the literature and reported on the electrocardiographic findings in Friedreich's ataxia. Russell in 1946 gave a detailed and accurate account of the pathologic changes found in the hearts of persons affected with this disease. Since then, scattered reports[5,10,17] have further emphasized the involvement of the heart in Friedreich's ataxia. From the evidence that is available, it is clear that certain cardiac abnormalities are definitely related to Friedreich's ataxia. These do not include such disorders, either acquired or congenital, which exist coincidentally, or the myocarditis secondary to intercurrent viral or bacterial infection which may occur in persons who have Freidreich's ataxia.

The usual clinical manifestations indicative of myocardial involvement are disturbances of rhythm and myocardial insufficiency terminating in congestive heart failure. Complete heart block with Stokes-Adams syndrome has been observed by Evans and Wright in siblings aged eighteen and twenty-two years. Piron believed angina pectoris was present in two brothers he observed.

Examination of the heart may reveal any of the cardiac arrhythmias alone or in various combinations. The heart may or may not be enlarged, and, in those patients who have acquired a kyphoscoliosis, it is displaced. Systolic and diastolic murmurs have been observed infrequently. Hejtmancik, Bradfield and Miller emphasized the diastolic murmurs heard in their two cases and in several cases reported in the literature, but murmurs of any type, especially diastolic, are the exception rather than the rule and are due to cardiac dilatation rather than to valvular disease.

The roentgenologic appearance of the heart is variable. The heart may be of normal contour or it may be globular; it may show varying degrees of left ventricular enlargement or generalized dilatation. In general, cardiac enlargement or dilatation is seen only late in the disease, and in association with far-advanced neurologic disease.

The electrocardiographic abnormalities are of two distinct groups:[11,15] those showing disturbances in impulse initiation and transmission, and those showing alteration of the ventricular complex. The former group includes such arrhythmias as paroxysmal auricular tachycardia, ventricular tachycardia, auricular fibrillation, auricular flutter, varying degrees of auriculoventricular block including first degree, second degree and complete heart block and the Wenckebach phenomenon, right bundle branch block, and various combinations of these disorders. The recorded observations are not sufficient to permit one to make a statistical analysis, but paroxysmal auricular tachycardia and auricular fibrillation are more commonly encountered than any other arrhythmia.

The modifications of the ventricular complex include slurring or low voltage of the QRS complex, deep Q waves, elevation or depression of the ST segment, and sharp, pointed, iso-electric diphasic or inverted T waves in one or more leads. These abnormalities may occur alone or in any combination. Great emphasis has been placed on the occasional finding of a Q_1 T_1 or Q_3 T_3 pattern simulating that found with anterior and posterior myocardial infarction, respectively, and on T_1 or T_3 patterns with "coronary type" T waves. However, when studies with multiple precordial leads were made,[6,17] evidence of a local myocardial lesion was always lacking.

Dr. Flipse is a Fellow in Medicine, Mayo Foundation, Dr. Dry is with the Division of Medicine, and Dr. Woltman with the Department of Neurology and Psychiatry, Mayo Clinic, Rochester, Minnesota.

The study of Evans and Wright of 38 patients with Friedreich's ataxia is significant in that they included patients whose disease from the neurologic standpoint was less far advanced than that of patients reported by other authors. They found definite abnormalities in the electrocardiogram of twelve of these patients, and, in all but one, who had complete heart block, the abnormalities were confined to the QRS complex. The changes were chiefly inversion of the T wave in one or more leads. Occasionally, all the limb leads showed these changes, and, in addition, some abnormalities occurred in widely separated precordial leads. They found that absent tendon reflexes and extensor responses of the plantar reflex, indicating more advanced neurologic disease, were more common in patients with abnormal electrocardiograms. Generally speaking, neurologic signs were more widespread in the patients who had the most conspicuous electrocardiographic changes. Electrocardiographic abnormalities also occurred more frequently in cases in which there was a family history of Friedreich's ataxia, and, finally, there was a marked tendency for members of the same family to have similar electrocardiographic patterns.

The pathologic changes considered by Russell to be characteristic although not pathognomonic consist of patchy loss of muscle fibers, infiltration with round cells and leukocytes, hypertrophy of muscle fibers, and separation of these fibers by an increase in fibrous or collagenous interstitial tissue. Pericarditis, endocarditis or organic valvular deformity was not noted by her. The presence of an interstitial myocarditis had been mentioned in a few reports before[12,13,16,18] and since[5,10] this study by Russell. She expressed the opinion that a focal, piecemeal coagulation necrosis of the muscle fibers takes place and is followed by cellular infiltration. As a result, the fibers are ultimately replaced by collagenous tissue, and the surviving muscle fibers undergo compensatory hypertrophy. This continues over a long period of time, until heart failure develops. At this terminal stage, a severe fatty degeneration is usual.

The theories advanced concerning the etiology and pathogenesis of the myocarditis and arrhythmias include the bulbar, the coronary artery, the infectious and the toxic theories.[11,15]

The bulbar theory, favored by the French,[1,2,8,9,19] is based on the occasional association of injury of the vagal nuclei and evidence of imbalance of the autonomic nervous system, such as paroxysmal cardiac arrhythmias, Cheyne-Stokes respiration, episodes of acute abdominal pain with ileus, and disturbances in temperature control, urine formation and sweating mechanism. However, these clinical findings are not present in the majority of cases, and Russell was unable to find evidence of injury of the vagal nuclei in her cases.

The coronary artery theory is based on the superficial resemblance of the described electrocardiographic changes to the patterns seen in myocardial infarction.[4] However, complete electrocardiographic studies with multiple precordial electrodes show no evidence of the focal type of myocardial injury[6,17] seen in myocardial infarction. Coronary artery disease was not evident at necropsy,[5,10,12,13,16,18,20] and injection of the coronary vessels showed no obstruction in even the finer ramifications of the coronary vessels.[14]

While it is impossible to prove that the myocarditis is not the result of either old or a recent infection so mild as to escape notice, its high incidence in patients with Friedreich's ataxia and its complete absence in unaffected members of the same family suggest that this is not the case. The progressive nature of the myocarditis over a period of several years is more suggestive of the continued action of some unknown agent than it is of the single insult of an acute infection. On the basis of pathologic findings, Russell, Lambrior, and Lannois and Porot concluded that the myocarditis is a result of toxins instead of infection. Available evidence suggests that the most valid theory is that the myocarditis is due to the action of an unknown toxin on heart muscle which may be abnormally susceptible to that toxin because of hereditary influences. It cannot be denied that purely neurogenic influences could be a factor in the production of the arrhythmias[3] but it is not necessary to postulate this mechanism in view of the presence of diffuse morphologic changes in the myocardium.

Contrary to current teachings that patients with Friedreich's ataxia die of intercurrent infection, it would seem that death due to an associated myocarditis is not infrequent. The appearance in these patients of any cardiac abnormality, either clinical, radiographic or electrocardiographic, is probably indicative of a poor prognosis. Certainly, cardiac enlargement, a major arrhythmia or congestive heart failure usually means death within a year or two. The course of the disease moreover does not seem to be influenced by the usual measures which are ordinarily effective in the control of congestive heart failure. Despite this a trial of therapy including digitalization, diuretics and quinidine in selected cases seems worth while.

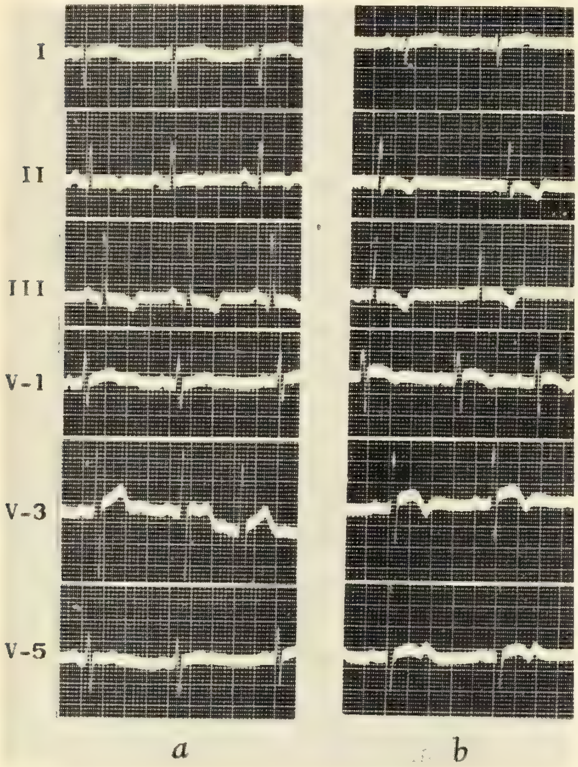

Fig. 1. *a*, Electrocardiogram of patient in case 1; *b*, electrocardiogram of patient in case 2

Report of Cases

Case 1.—An eighteen-year-old white man, who was a high school graduate, was brought to the Mayo Clinic on August 4, 1949, because of difficulty in walking. He had been delivered with the aid of forceps but his neonatal and infancy development had been normal. At the age of six years, it had been noted that he was unable to run, jump or hop and that he had difficulty in walking because of unsteadiness and inco-ordination of the ankles. Soon thereafter, slight inco-ordination of the upper extremities had been noted. These difficulties had progressed gradually without remission during the subsequent twelve years. His general health had been excellent. He had not had any cardiorespiratory symptoms, or indeed any symptoms except those referable to the neurologic disorder.

Physical examination revealed an adequately developed and nourished white male of 18 years with moderate kyphoscoliosis but no deformity of the feet. The cardiorespiratory system was completely normal as were the results of the remainder of the general examination. Neurologic examination revealed a marked ataxia, absence of all tendon reflexes, and bilateral extensor responses of the plantar reflex. It also revealed gross inco-ordination with dysmetria and adiadokocinesis. Romberg's sign was present. The joint sense in the great toe was absent, and there was delayed pain sense in the feet. Nystagmus was absent. The ocular fundi were normal.

The results of routine laboratory tests and roentgenographic examination of the heart, lungs, head and pelvis were normal except for the presence of kyphoscoliosis. The electrocardiogram (Fig. 1*a*) was abnormal, for it showed right axis deviation, occasional auricular extrasystoles, notched QRS_1, slurred QRS_3, inverted T_2 and T_3 and diphasic T in lead V_5. The T wave was positive in leads V_1 and V_3.

A diagnosis of Friedreich's ataxia with myocarditis was made.

Case 2.—The twelve-year-old brother of the patient in Case 1 was also seen at the same time. He had nearly identical but milder symptoms. The onset of his disease was uncertain but it probably had occurred when he was between 6 and 8 years of age. It then had been noticed that he was awkward in running and walking and often stumbled or fell. There had been little or no progression of his symptoms since they first had been noted. As with the brother, there was complete absence of cardiorespiratory and other symptoms.

The results of general physical examination were normal except for the presence of slight lumbar scoliosis. Neurologic examination revealed less marked ataxia and inco-ordination, but the same reflex changes as were present in the older brother, namely, absent tendon reflexes and bilateral extensor plantar reflexes. Sensation, however, was normal. There were slight nystagmoid motions but definite nystagmus was not present.

The results of routine laboratory tests and roentgenographic examination of the heart, lungs, head and spinal column were normal except for the presence of slight lumbar scoliosis. The electrocardiogram (Fig. 1*b*) was even more abnormal than that of his brother. It showed right axis deviation, slurred QRS_1, inverted P_3, inverted T_2 and T_3, inverted T and elevation of the ST segment in leads V_1 and V_3 and diphasic T in lead V_5.

The diagnosis in this case also was Friedreich's ataxis with myocarditis.

The parents and two remaining siblings, aged thirteen and sixteen years, were then examined. None had symptoms of neurologic or cardiorespiratory disease. There was no evidence of Friedreich's ataxia, pes cavus or cardiac disease. Their electrocardiograms were all normal.

Comment

Our observations on these two brothers are partly in agreement with those of Evans and Wright in that the two neurologic signs most frequently seen in patients with electrocardiographic abnormalities, namely, an absence of tendon reflexes and an extensor response of the plantar reflex, were present in both cases.* They represent another example of the observation that afflicted members of one family tend to have similar electrocardiographic patterns. We have no explanation for the finding of more marked electrocardiographic changes in the younger of the two patients in whom neurologic damage was less marked, but emphasize it because it is contrary to previous experience. The extension of electrocardiographic abnormalities across the entire precordium in this latter case gives further support to the belief that most, if not all, of the cardiac abnormalities associated with Friedreich's ataxia are due to a diffuse myocarditis. The cause of this myocarditis is unknown but it is probably of toxic cause.

---

*Since this paper was completed, the report of G. W. Manning (Cardiac Manifestations in Friedreich's Ataxia. Am. Heart J., 39:799-816 [June] 1950) has been published. It emphasizes the clinical and electrocardiographic aspects of the cardiac arrhythmias and heart failure noted in four of six patients with Friedreich's ataxia. Myocarditis similar to that described by Russell was found at necropsy in one case.

CORONARY THROMBOSIS IN THE YOUNGER AGE GROUPS

(Continued from Page 999)

This further observation was made. If the patient was allowed to smoke cigarettes, he frequently was threatened with a syndromal attack. On suspicion, these few tests were run on normal people (Table III).

From this meager evidence, it may be that cigarette-smoking acts not only to constrict the arterial lumen but, what may be more dangerous, to lower the prothrombin time level.

It is known, of course, that a high percentage of people subjected to these same conditions, tension, dietary indiscretions, and smoking, survive into an older age group. There must, then, be some common factor that determines the precipitation of coronary attacks at different ages. We believe this factor to be the difference in prothrombin time level. We believe that this difference in level is a hereditary factor, and that it plays an important rôle in coronary attacks. Therefore, we believe that coronary attacks are predictable and preventable.

Assuming, then, that this reasoning is correct, should it not be reasonable to assume that by routine testing, individuals prone to coronary disease could be detected and prophylactically treated with dicumarol to elevate the prothrombin time to a satisfactory and safe level just as the diabetic individual can be detected and treated?

We realize, of course, that a prolonged research would be required to establish the proof of this reasoning. Even a few hundred selected people tested and followed through the years should establish the veracity of this contention. We believe, however, that such research in prothrombin time levels would be justified in an attempt to prevent the colossal cost in heart deaths exacted by our modern high-geared society.

CHRONIC LEUKEMIC INFILTRATION OF THE GASTRIC WALL SIMULATING PEPTIC ULCER

ROBERT H. CONLEY, M.D.
Mankato, Minnesota
and
J. ALLEN WILSON, M.D., Ph.D.
Saint Paul, Minnesota

THE FIRST description of gastric involvement in a case of apparent leukemia was given by Briquet in 1838 and published in Cruveilhier's Atlas of Anatomy. In this case, the mucosa of the stomach and bowel was thrown into folds resembling cerebral convolutions. Since then, as reported by Pearson, Stasney and Pizzolato,[11] in all descriptions of autopsies on lymphatic leukemia patients, various authors have stressed the diffuse involvement of the mucosa and submucosa of the stomach, usually without involvement of the deeper layers. These authors reported two similar cases.

Various pathologists since Cohnheim have recognized anatomical changes in various organs, in leukemia, without changes in the blood. Cohnheim[2] suggested the name "pseudoleukemia." Warthin[15] designated the condition a generalized or localized "aleukemic lymphocytoma." Ewing[3] observed: "The gastrointestinal tract is a seat of a remarkable form of primary lymphoid hyperplasia which lacks the destructive character of lymphosarcoma and fails to give lymphocytosis of the blood. The process may be chiefly limited to a portion of, or involve the whole of, the gastro-intestinal tract, or it may be associated with widespread lesions of most of the other lymphoid structures." Ewing[3] designated this as "aleukemic lymphomatosis." Ikeda[5] in 1931 described a case of gastric tumor and infiltration thought to be carcinoma, on whom a gastro-enterostomy was done. After five years the patient died of almost generalized lymphatic leukemia and heart failure. The entire gastro-intestinal tract was involved. In this case the infiltration extended out into the muscularis and serosa. The mucosa in the upper part of the stomach showed the thickened rugae described by Briquet. Ikeda[5] found, in 12,396 autopsies at the University of Minnesota, seventy-seven cases of leukemia of which fifty-one were of the lymphatic type and twenty-six of the myelogenous type. Of the former, only two cases showed local nodular elevation or thickening of the gastric wall, and two showed ulcers. In the myelogenous type, only one showed a local thickening of the mucosa. Grossly these lesions could not be differentiated from those of Hodgkin's disease or of lymphosarcoma. Ikeda[5] recommended abandoning use of the term "pseudoleukemia gastro-intestinalis" since it included all of the above types of lymphoblastomata. According to Mead,[8] the pathologic character of lymphatic leukemia of the gastro-intestinal tract varies from slight swelling of the mucous membrane and lymph follicles to extensive hyperplasia of the lymphoid tissue of the entire gastro-intestinal tract, with associated generalized lympadenopathy. The process may be limited to one organ or to the whole gastro-intestinal tract. Polypoid formations anywhere in this tract are common. The stomach mucosa often exhibits enlarged convolated rugae. Ulceration of the mucosa is infrequent. Mead[8] states that the muscularis is uniformly uninvolved. Gastro-intestinal Hodgkins Disease is uncommon but ulceration is relatively common in this disease as it is in lymphosarcoma. In the leukemias, as recorded by Paul and Hendricks,[10] one often finds small areas of thickening and infiltration of the mucosa, and in such thickened areas the mucosa may become denuded resulting in shallow ulceration and hemorrhage.

Forkner[4] states that pseudoleukemia (aleukemia) seems more likely to give gastro-intestinal involvement than do cases where the blood picture is positive for leukemia. He also emphasized the difficulty of differentiating the gross alterations in the gastro-intestinal tract caused by leukemia, aleukemia, lympho-sarcoma and Hodgkin's Disease. In contrast to the infrequentcy of leukemia of the gastro-intestinal tract, O'Donohue and Jacobs[9] collected a series of 100 cases of

Dr. Wilson is Clinical Assistant Professor of Medicine, University of Minnesota Medical School, and consultant in internal medicine, U. S. Veterans Hospital, Minneapolis.

lymphosarcoma of the stomach reported by various authors from 1937 through 1946. Poer[12], Macchi[7] and Koucky, Beck and Atlas[6] have given separate descriptions of acute perforations of lymphosarcomatous ulcers of the stomach and duodenum which presented clinically as peptic ulcers. This is extremely rare in leukemia.

The intensity of symptoms in lymphatic leukemia of the gastro-intestinal tract seems to have no constant relationship to the extent of the pathologic changes. The most extensive lesions may be symptomless. Achlorhydria is an occasional finding. Areas of hemorrhage or small ulcers due to secondary infection may occur in some cases. There may be profuse hematemesis, bloody diarrhea, loss of appetite, weight loss and weakness. An abdominal mass may be present. These symptoms cannot be differentiated from those of other lymphoblastomata or of carcinoma. The x-ray is of little value in diagnosing any lymphoblastoma; most cases have been called carcinoma. Ikeda[5] states that the demonstration of deep heavy rugal impressions on the x-ray, together with a postive blood picture or biopsy, may be helpful in diagnosis of gastric leukemia but he emphasized that there is no pathognomonic roentgen picture of the stomach in the gastric manifestation of lymphatic leukemia.

The use of the gastroscope in the diagnosis of lymphoblastoma of the stomach was introduced by Schindler[14] in 1922. However, he stated in his first edition in 1937 that no case of leukemia or aleukemia of the stomach had ever been observed gastroscopically. In his 1950 edition he states that gastroscopy often yields important results in leukemia. Hypertrophic gastritis may be seen in myeloid leukemia and atrophic gastritis is more apt to be seen in lymphatic leukemia. Leukemic infiltrations are visible at times. Schindler[14] finds that the differentiation between Hodgkin's disease, lymphosarcoma, leukemia, some types of gastritis, carcinoma or syphilis of the stomach cannot be made from the gastroscopic picture alone. The diagnosis can be made only if biopsy of a lymph node reveals the typical picture and a diffuse stiff infiltration is seen. Leukemic infiltration and Hodgkin's disease of the stomach will be suspected only if other signs of these conditions are present elsewhere. In difficult cases, Schindler[14] recommends biopsy at laparotomy without the intent of resection. The biopsy should be taken from the area which was suspicious at gastroscopy. The abdomen then is closed and paraffin microscopic studies of the biopsied tissue are run. In lymphoblastoma, irradiation then is used. If syphilis is found, treatment is started. Carcinoma is promptly resected.

Renshaw and Spencer,[13] in 1947, found no reports available of the gastroscopic appearance of leukemic, pseudoleukemic or Hodgkin's infiltrations of the stomach, but judging from autopsy descriptions of such lesions, these authors were of the opinion that the lesions would be indistinguishable from carcinoma or lymphosarcoma. They described the gastroscopic appearance of eight cases of gastric lymphosarcoma, in six of which a diagnosis of infiltrating or ulcerative carcinoma was made. In the other two cases, cervical lymph nodes pointed to the proper diagnosis. They state that there is no characteristic gastroscopic picture of lymphoblastoma.

The gastroscopic examination of patients with malignant lymphomata at the University of Iowa has been well described by Paul and Hendricks.[10] All patients at that institution who are found to have any type of lymphoma are routinely gastroscoped. From 1941-1947, 53 patients with malignant lymphoma were found by such examination to show characteristic involvement of the stomach while during this same period only fifteen cases were found at autopsy to have gastric lymphomatous lesions. Of these fifty-three patients, twenty-two had chronic lymphatic leukemia, ten had myelogenous leukemia, one had monocytic leukemia, and twenty had Hodgkin's disease. There was no correlation in these cases between the type and duration of symptoms, degrees of free HCl or the extent of involvement. The ages ranged from nineteen to seventy-five years. The authors state that the gastroscopic picture was no indication of the type of hematopoietic neoplasm present. The most frequent gastroscopic finding was a granular mucosa suggestive of "goose pimples," seen usually on the anterior wall near the angulus (Depth II). The next most common site was the posterior wall of the antrum. These granular elevations appear as highlights on a dry mucosa and at times are 1 mm. in diameter and large enough to project above the surface. The same appearance was found in some of these patients in the mucosa of the rectum and sigmoid. Here they differ from the mucosal findings in chronic ulcerative colitis in being fewer in number and of larger size. The color of the gastric mucosa in these cases varied with the degree of anemia present and the mucosa often presented gelatinous areas of edema with small hemorrhages. The second type of lesion seen through the gastroscope in these lymphoma cases was a nodular mass, not over 1 cm. in diameter, surrounded by abnormal appearing mucosa, often hemorrhagic. These usually were near the cardia, more often on the posterior wall. One such nodule was later examined at necropsy and found to be an infiltration of lymphatic leukemia. The third, and least common type of lesion seen in these cases was an ulceration. Two such ulcers were found, both in Hodgkin's disease, and both were on the greater curvature. The authors conclude that hematopoietic neoplasms involve the stomach with greater frequency than the medical literature would indicate. Since the mucosa and submucosa are involved, gastroscopic evaluation is made possible and is very helpful.

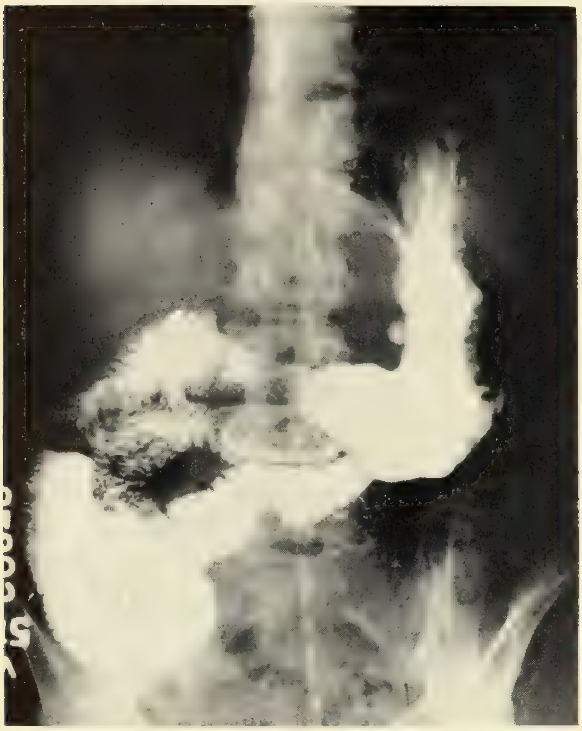

Fig. 1. Large penetrating gastric ulcer on the lesser curvature just above the incisura. It appeared benign both to the roentgenologist and to the gastroscopist.

Very recently, Benedict[1] has reported on the use of the flexible operating gastroscope in the diagnosis of lesions of the stomach. He reported such biopsies to be of definite value in the diagnosis of lymphoma, carcinoma and gastritis. Sixty-three biopsies had been done without accident or complications. For obvious reasons, the method has not been used or recommended for differentiation of benign from malignant gastric ulcers. Since lymphoma is usually a diffuse process, Benedict[1] thinks that a negative biopsy probably excludes this diagnosis with reasonable certainty. (In view of the work just described, by Paul and Hendricks,[10] such an assumption might be open to question.) If doubt exists and lymphoma seems likely clinically, gastroscopy and biopsy should be repeated, taking the latter from a new area of the gastric mucosa.

As to treatment of the gastric lesions of hematopoietic neoplasm, Paul and Hendricks[10] report that irradiation and nitrogen mustard had little, if any, effect on the gastric involvement. In some cases the lesions progressed after these agents were used. Watkins,[16] however, has found considerable benefit from the use of nitrogen mustard in adequate dosage. Schindler[14] recommends surgical biopsy and if this is positive for lymphoma, irradiation is then given. Mead[8] stated that the best results in treating lymphatic leukemia of the stomach were obtained by combined surgery and x-ray therapy.

Case Report

A white, retired postal employe, aged fifty-nine, was admitted to the Minneapolis Veterans Hospital on October 7, 1949. The patient was complaining of generalized malaise, sore throat of two weeks' duration, rhinitis and sinusitis of three weeks' duration and inability to maintain himself on his ulcer regime at home.

Past history revealed that his first admission to the hospital was in 1931 at which time a diagnosis of chronic duodenal ulcer was made; the diagnosis was confirmed by roentgenologic study. In 1940, he was readmitted because of persistent vomiting, epigastric pain and a weight loss of 25 pounds. A duodenal ulcer was again demonstrated and the symptoms promptly subsided with conservative therapy. Precordial pain and shortness of breath were listed as additional complaints.

A severe attack of precordial pain, with radiation of pain into the left arm and hand, associated dyspnea and profuse diaphoresis necessitated emergency hospitalization in 1945. Therapy was exercised in keeping with a diagnosis of acute coronary occlusion. However, serial electrocardiograms failed to reveal infarction, or evidence for coronary insufficiency. Numerous electrocardiographic studies done since that date have continued to demonstrate normal tracings.

Precordial pain of ten days' duration, partially relieved by sublingual nitroglycerine, was the inciting cause of his readmission in June, 1947. Laboratory studies at this time revealed a persistently elevated white blood cell count ranging between 17,000 and 32,000. Biopsy of a small node in the right axilla revealed chronic lymphatic leukemia; this was confirmed by bone marrow biopsy. X-ray films of the upper gastro-intestinal tract were again made, which revealed a filling defect in the midportion of the body of the stomach. This was thought to be of questionable significance; duodenal deformity was again noted. From June, 1947, until January, 1949, follow-up studies at three-month intervals were carried out. At the time of each reexamination, precordial pain and epigastric distress continued to be the main complaint. During this interval the spleen and liver became palpable and the lymph nodes became more prominent. Repeated white blood cell counts were in the range between 60,000 to 80,000 with 80 to 90 per cent mature lymphocytes; occasional immature lymphocytes were observed.

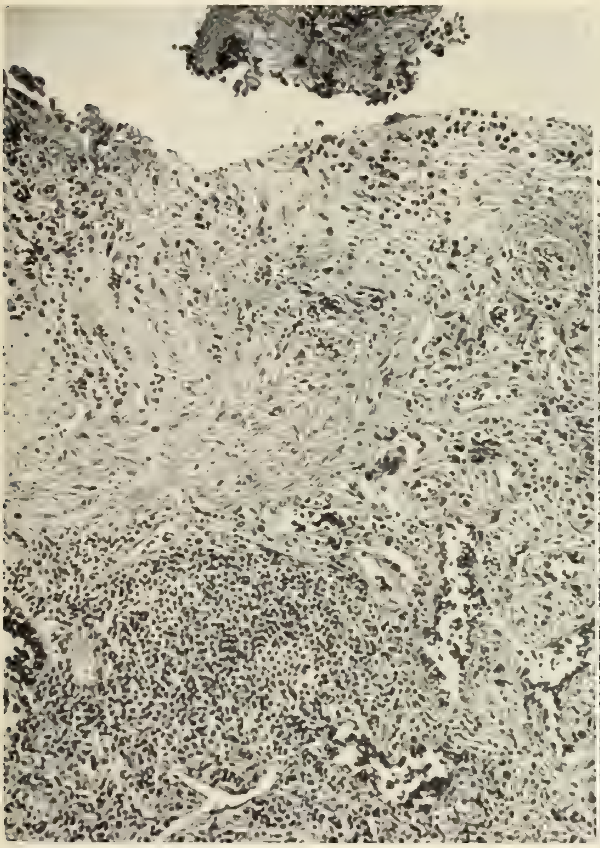

Fig. 2. Microscopic section through the base of the gastric ulcer. Necrotic debris, proliferating fibroblasts, and an underlying diffuse lymphocytic infiltration are noted.

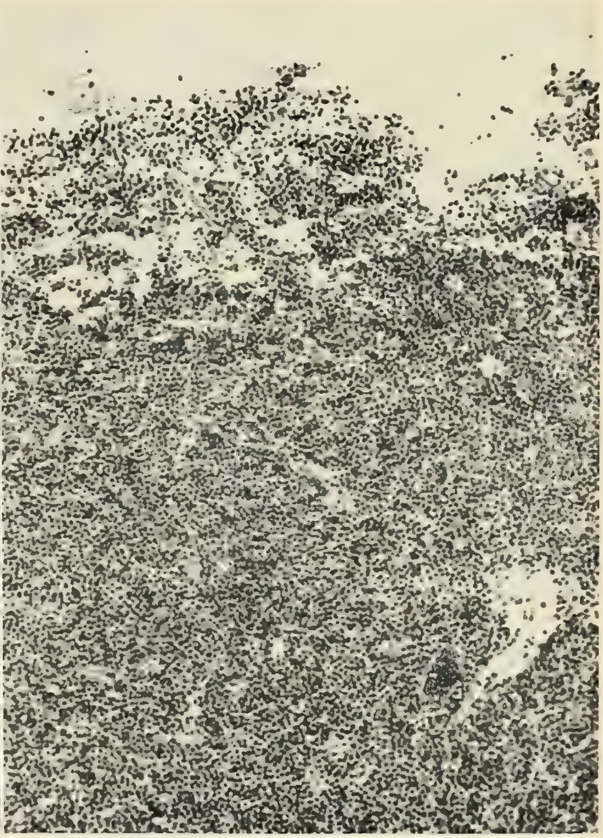

Fig. 3. One of the large collections of lymphocytes found in the submucosa. Others were found in the muscular layer and in the serosa.

During the latter part of January, 1949, the patient was again admitted as an emergency because of nausea, vomiting, 10 pound weight loss, epigastric distress, and precordial pain. An upper gastro-intestinal study was done and a gastric ulcer was observed on the lesser curvature and posterior wall (Fig. 1). A crater in the duodenal bulb was also noted. Gastroscopy was carried out and a large penetrating gastric ulcer on the lesser curvature about one inch above the incisura was observed. The crater was approximately 1.75 cm. in diameter. The membrane lining the crater had a smooth greyish white color. The rim of the crater was moderately edematous and only slight injection surrounded the rim of edema. Gastroscopy and x-ray studies were carried out at two-week intervals. Examinations done seven weeks after the first examination revealed complete healing of the previously reported ulcer.

Despite visits at two months' intervals, the patient sought emergency readmission in August, 1949, because of intractable epigastric distress, nausea, vomiting and a 15-pound weight loss, which had occurred in a period of four days. Fluid balance was restored and ulcer management was continued. Nightly aspirations were carried out and residual retention ranged from 50 c.c. to 300 c.c. The patient was taught to use an Ewald tube. It was decided that with lymphatic leukemia, and coronary insufficiency, surgery should be deferred until it was actually imperative to relieve obstruction. Gastro-intestinal studies at this time demonstrated a minimal residual of the gastric ulcer on the lesser curvature and a duodenal deformity.

At the time of admission on October 7, 1949, physical examination revealed a thin, undernourished male who appeared acutely ill. The blood pressure was 142/76, pulse 116, respirations 22, temperature 101.4° Fahrenheit. The mucous membrane of the nose and throat were congested and a purulent post-nasal drip was observed. Signs of right upper lobe consolidation were present. A soft systolic murmur was heard at the apex and the heart was enlarged to the left. The liver and spleen were palpable on deep inspiration. Tenderness and muscle guarding were present in the midepigastric region. Shotty nodes were found in the cervical chains bilaterally and both axillary and inguinal regions.

The hemoglobin was 12.1 grams, white blood cell count 83,000 with 15 per cent neutrophils and 85 per cent mature lymphocytes, sedimentation rate 98 mm. per hour, serum proteins 6.7 grams with 4.4 grams of albumen and 2.3 grams of globulin. Prothrombin time was 100 per cent of normal. Bromsulfalein: 2 per cent retention in 45 minutes. Serum bilirubin: 1 minute, 0.2 mg. per cent; total, 0.5 mg. per cent. Gastric analysis: total acid 44°, free acid 36°. Stools were negative for ova, parasites and occult blood. Urinalysis showed a trace of albumen and an occasional white blood cell. Sputum cultures revealed the usual mouth organisms. X-ray studies of the chest revealed a diffuse infiltration in the right upper lobe. Electrocardiogram again showed a normal tracing.

The patient was placed on penicillin and the fever promptly subsided; however, pleural effusion developed and required repeated aspirations. Cultures of the aspirated fluid were repeated negative. Following subsidence of the inflammatory process an upper gastrointestinal study was carried out and an ulcer crater was visualized on the lesser curvature. Gastroscopic study at this time demonstrated a one cm. crater, penetrating in nature, 2 cm. above the incisura slightly to the posterior wall side on the lesser curvature. The ulcer crater was covered by a smooth glistening gray membrane. No heaping up of the ulcer margin was seen; a slight rim of edema surrounded the crater.

In spite of intensive therapy the crater continued to enlarge and the patient was transferred to the surgical service. Two days prior to scheduled surgery, the patient became faint, weak and passed numerous tarry stools. The hemoglobin level dropped to 7.9 grams. Three thousand c.c. of whole blood were required to restore his hemoglobin level to 14 grams. Subtotal gastrectomy was carried out and the postoperative course was uneventful.

Examination of the resected portion of the stomach revealed a depressed area on the lesser curvature which appeared to be a healed ulcer. Immediately adjacent to this area, an elliptical ulcer with slightly rolled edges 1.2 by 2.5 cm. was present. The base of the ulcer was necrotic but was not indurated. In the pyloric portion of the stomach, on the anterior wall and midway between the greater and lesser curvature, an old healed ulcer was represented by puckering at this spot.

Microscopic studies revealed the base of the ulcer to be composed of necrotic debris and some slight proliferating fibroblastic tissue (Fig. 2). The ulcer was relatively superficial, extending only into the inner muscular coat. The mucosa became thinner and just faded off at the edge of the ulcer. Underlying the ulcer was a diffuse lymphocytic infiltration which extended through the musculature and became particularly heavy in the serosa. Large collections of lymphocytes were found in the submucosa, musculature and serosa of the stomach wall near the ulcerated area, (Fig. 3) and similar collections were found in all portions of the stomach sectioned, whether near or far from the area of ulceration. These masses of lymphocytes were found diffusely throughout the stomach wall and were arranged in such discrete units that they did not give the appearance of an inflammatory process, but rather of leukemic infiltration of the stomach wall. Abdominal nodes removed at the time of surgery showed the normal architecture to be completely wiped out by a homogeneous sheet of lymphocytes consistent with a diagnosis of lymphatic leukemia.

Conclusions

1. The literature is reported describing the gastric manifestations of lymphatic leukemia.

2. Ulceration of the gastric mucosa is extremely rare in lymphatic leukemia of the stomach. When present it is almost always of a superficial type, amounting only to small erosions. Deeper ulcers, resembling peptic ulcers in a nonleukemic stomach, have not been described in the literature.

3. A case is reported where recurrent ulceration, resembling peptic ulceration, both by x-ray and gastroscopy, was found on the lesser curvature of the stomach in a patient with proved systemic lymphatic leukemia. Gastric resection was finally performed. The pathological examination of the resected specimen revealed typical chronic lymphatic leukemia infiltration of all layers of the gastric wall.

CILIARY ACTION AND ATELECTASIS

A. C. HILDING, M.D.
Duluth, Minnesota

THE physiology and physics of the movement of oxygen and other gases in the lungs seem to be well understood. The partial tensions of the gases in alveolar air have been measured, and the observed physiologic steps are consistent with the known laws of physics. Removal of entrapped air under pathologic conditions in the lungs and elsewhere is not so completely understood. For instance, it seems to be generally believed that the air from a lung portion which becomes atelectatic is removed by absorption alone. It is held that a plug of mucus, of such great viscosity that the cilia are unable to handle it, corks a bronchus and that the air behind it is completely absorbed.[5,9,10,11] Sometimes the opinion is ventured (seemingly without any direct evidence) that ciliary action is subnormal or has ceased entirely.

In many respects, this view appears to be essentially correct. There seems to be no doubt that air can be removed from an obstructed lung by absorption alone. This has been demonstrated experimentally[1,2,3] and seemingly happens in the presence of tumors and some foreign bodies. There are, however, discrepancies which make one suspect that other factors are involved. Pathologists and endoscopists sometimes find masses of very viscid mucus, but, more often, it is soft. The negative pressure associated with atelectasis may be considerable—34 mm. of mercury has been measured. It is sufficiently strong to move the mediastinum to one side or the other and to practically immobilize the chest wall. One would suppose that the soft mucus would slide down into the area of negative pressure, but this it does not do. The absorption of air experimentally requires sixteen hours,[1,2,3] and postoperative atelectasis develops much more rapidly than that; surgeons have told me that it develops on the table. Thick, viscid casts of mucus, which are incorporated in the bronchial wall, do form in asthma and are demonstrable at necropsy. The result, however, is not atelectasis but rather the opposite, emphysema. That cilia cannot handle viscid mucus appears to be in error also. Tests which I made in the open frontal sinus of an anesthetized dog indicated that viscid mucus can be removed more readily than very thin mucus. In these experiments, it was lifted en masse from the bottom of the sinus and carried to and through the ostium, occluding the latter completely during its passage.

It has been taught that the bronchial tree increases its cross-sectional area with each subsequent branching and that a composite bronchial tree would look like an inverted funnel. If this concept were accurate it might be possible that a viscid plug of mucus, carried upward in the bronchial tree, would become lodged in the narrowed stream bed. My son and I made some measurements, however, of the bronchial tree which indicated that the concept of the inverted funnel applied to the bronchial tree is not correct, at least in bronchi larger than 1.5 mm.

The question arises whether, according to the known laws of physics, it would be possible for the air to be completely absorbed from an obstructed lobe subjected to a negative pressure of the magnitude found in atelectasis.

It may be of value to review the steps by which air is absorbed from different portions of the body in the light of known physical laws. We naturally think of the lungs first. The tidal respiratory flow while at rest is about 500 c.c.; 150 c.c. of each breath remain in the dead space of the bronchial tree; the other 350 c.c. flow into a residual volume of 2,500 c.c. Here a rather complex situation is set up due to the differences in the partial gas tensions in alveolar air and atmospheric air. Diffusion is a necessary step in bringing the fresh oxygen to the alveolar wall where exchange of gases with the blood takes place. Oxygen molecules move at the rate of about 200 meters per second at room temperature; however, they bump into other molecules so frequently that the diffusion rate is very much smaller.

A physicist friend has given me the following formula for the diffusion of air at standard conditions of temperature and pressure: $r = 3.5 \times$ the square root of t ("r" represents the average mean distance in centimeters traveled by the molecules as though they emerge from a point and move outward in all directions without obstruc-

---

Presented at the annual meeting of the Minnesota State Medical Association, Duluth, Minnesota, June 12, 1950.

tion and "t" is the time in seconds). Working this out, r = about 35 mm. per second. The alveoli are approximately 0.2 mm. in diameter or 0.1 mm. in radius. This means that, during the one second which the air remains in the alveolus during inspiration, an oxygen molecule starting from the center of an alveolus could make the trip to the wall about 350 times. The picture then of the gases from the inflowing air (oxygen, carbon dioxide, nitrogen and water vapor) is that of the contained molecules flying rapidly in all directions and making contact with the walls of the alveolus from 1 to 400 times a second. The rate of absorption into the blood would depend upon, first, the nature of the interposed membranes; second, the comparative pressures of the gases in the blood and in the alveolus and, third, the relative solubility of the gases in the blood plasma.

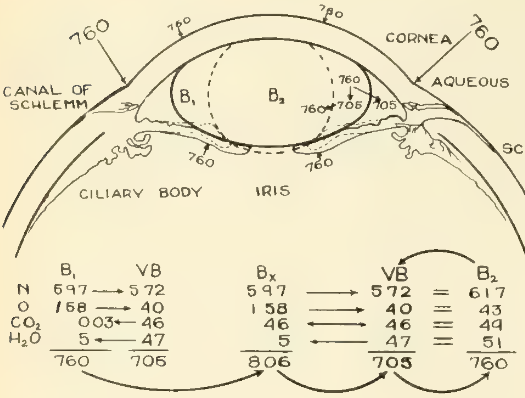

Fig. 1. Diagram representing an air bubble injected into the anterior chamber of the eye. The figures in the column under B_1 are the partial pressures of the various gases contained in the injected air. Column VB gives the values in venous blood. It is assumed, for the purposes of this study, that the values are the same in the aqueous humor of the eye, although they probably differ somewhat. Since CO_2 diffuses more rapidly than the other gases, this gas would pass from the aqueous into the bubble faster than O_2 would dissolve. Therefore, at first, the pressure would increase, as indicated in Bx, if the volume should remain unchanged. The exchange of the other gases would soon take place as indicated between Bx and VB. Equilibrium would be established at 705 mm. of pressure—if the volume should remain constant. The volume, however, does not remain constant since the yielding walls of the eye are subject to an atmospheric pressure of 760 mm. The volume would shrink until the pressure was equalized. Then the gas tensions would all be too high, as in B_2, and movement of molecules would continue into the aqueous, again causing a further fall in pressure. Equilibrium could not be attained and all of the air would be absorbed.

Let us take a simpler example, for the moment, than that of the alveolus. In cataract surgery, we sometimes inject air into the anterior chamber at the end of operation in order to prevent adhesions between the iris and the incision. From four to six days are required for such a bubble in the anterior chamber to be absorbed. Let us follow the steps as we feel they must be, according to physical law (Fig. 1).

The partial gas pressures in the atmosphere are given about as follows: oxygen 158 mm. of mercury, carbon dioxide 0.03 mm., nitrogen 597 mm. and water vapor 5 mm. (water vapor, of course, varies widely) making a total of 760 mm. of pressure. The partial pressures of the aqueous are between those of the arterial and the venous blood; oxygen is given at 40 to 45 mm. and carbon dioxide about 45 mm. The aqueous is produced in the ciliary body through a combination of dialysis, filtration and secretion. Oxygen, nitrogen and carbon dioxide molecules are roughly about the same size as water and would, therefore, probably pass through the capillary walls, the stroma and the endothelium of the ciliary body about as rapidly as water, and, therefore, the concentrations would be much the same as in arterial blood. (Again, a reservation must be made, remembering that filtration may be interfered with by the processes of secretion). The aqueous serves the metabolic needs of the lens, portions of the cornea and iris and probably other structures as well. In this metabolism, it undoubtedly loses oxygen and picks up carbon dioxide, as in the metabolism of tissues everywhere. It leaves the eye by several different routes, including the canal of Schlemm, through which the aqueous is in direct contact with venous blood with no intervening membranous barrier.

Let us assume, for our purposes, that the gas tensions present in the aqueous are the same as those in the venous blood. Those given for the venous blood are: oxygen 40 mm. of mercury, carbon dioxide 46 mm., nitrogen 572 mm. and water 47 mm., making a total of 705 mm., or 55 mm. less than that of the atmosphere. The following steps would occur during absorption of the air bubble in the anterior chamber: The 0.03 mm. of carbon dioxide would be rapidly increased to 46 mm., because the movement of carbon dioxide is some thirty-five times as fast as that of oxygen. Meanwhile, the 158 mm. of oxygen would be reduced more slowly to 40 mm. The bubble would first increase in size or pressure because of the rapid movement of the carbon dioxide; the nitrogen moves much more slowly than either oxygen or carbon dioxide and, for purposes of simplification, can be assumed to stand practically still. The carbon dioxide, having reached equilibrium before the oxygen, would find itself at a higher tension in the bubble as the latter moved out. If the bubble remained constant in size, the carbon dioxide would move back into the aqueous and the oxygen would continue to move into the aqueous until equilibrium would be established with a net loss in pressure of 72 mm. However, since the eye is subjected to atmospheric pressure, disregarding for our purposes the intraocular pressure, the air bubble would not remain the same in size but would shrink until the pressure again equalled 760 mm. As soon as this happened, then the tension of the carbon dioxide, oxygen and the nitrogen would be greater in the bubble than in the aqueous, so all three would again move from the bubble into the aqueous—the carbon dioxide very rapidly, oxygen much more slowly and the nitrogen still more slowly. This would once more be followed by shrinkage of volume and the whole process would be repeated. Equilibrium would never be established, and eventually all of the gases in the bubble would be dissolved in the aqueous.

Taking another example from our field of work, negative pressure sometimes develops within the sinuses. Assuming that the ostium should become completely blocked while the sinus was still full of air, through what physical steps would the gases of the air pass and what would be the eventual pressures? Conditions in the sinuses are far different from those in the alveolus of the lung or those in the anterior chamber of the eye. In the eye, the air is in direct contact with the aqueous, there being no interposing membranes. In the alveolar wall, there is at least one interposing membrane—the capillary wall. In the sinus, there is the capillary wall, a connective tissue stroma and a cuboidal type of epithelium, which is at least two cells deep. It would seem that these interposing structures would increase the time of the passage of gas molecules from the interior of the cavity into the blood stream. Moreover, the blood supply to the sinuses is normally very meager, and still another factor is that the sinus wall carries both oxygenated arterial blood and venous blood, while all of the blood entering the lungs is venous blood, from the standpoint of gas content.

Despite these handicaps, carbon dioxide would eventually find its way from the capillaries into the sinus cavity, oxygen would move less rapidly from the cavity into the venous blood, and, still more slowly, nitrogen would find its way into the blood stream. The total pressure within the sinus would rise at first because of the inflow of carbon dioxide molecules, but, eventually it would begin to fall, as was the case in the eye. However, the sinus walls being rigid, there would be no decrease in volume and, therefore, the pressure, after the initial rise, would fall progressively until equilibrium would be established. If there were only venous blood present in the capillaries, the pressure theoretically would fall to 705 mm. of mercury, the same as the gas pressure of the venous blood. However, the gas pressure of the arterial blood is 757 mm., therefore, the gas molecules would escape from the arterial blood into the cavity as they were removed from the cavity into the venous blood. Theoretically, equilibrium should be established at a pressure somewhere between 705 and 757 mm., probably in the neighborhood of 725 mm. The volume would remain the same as when closure of the ostium began (excluding, of course, such things as edema and secretion).

As a further illustration, the middle ear furnishes an example of conditions between those in the eye and in the sinus. Herbert,[6] of Upsala, on introducing rubber balloons into the nasopharynx and inflating them in such a way as to close the eustachian tubes, has found that in about thirty minutes there is a marked retraction of the ear drum, which he assigns to the reduced pressure following oxygen absorption. Here are conditions midway between those in the eye, where there is an external positive pressure and yielding soft walls, and those of the sinus, where the walls are rigid and there can be no reduction in volume. That portion of the lateral wall of the middle ear which is comprised of the tympanic membrane is more or less yielding and the volume of the space is reduced somewhat. Therefore, the air in the middle ear would be more completely absorbed than that in the sinus. Still it is not possible for all of the air* to be absorbed; equilibrium would eventually be established at a pressure somewhere between the gas pressures of the arterial and the venous blood. One would infer the time required, as in the case of the sinus, would be long compared with that of the lung.

In the thorax, too, the tissues about an obstructed lobe of the lung are not free to yield as completely as those about the bubble in the eye (Fig. 2). The wall of the thorax is more or less rigid and a negative pressure develops within it.

---

*Again, excluding such things as secretion, edema and other changes in the lining epithelium.

However, absorption can go on until the negative pressure equals the difference between the gas pressures in the alveolus and the gas pressures in the venous blood. This difference approximates 55 mm. of mercury. Theoretically then, there could be established a negative pressure of 55 mm. of mercury before equilibrium would be established and the absorption of gases would cease. The greatest negative pressure which has been measured in collapse of the lung is about 34 mm. of mercury,[4] so, theoretically, all of the air from an obstructed lobe of the lung could be completely absorbed, provided 55 mm. of negative pressure is not exceeded. However, a certain amount of time is required for absorption of gases, even from the lung. Coryloss and Birnbaum[1,2,3] report experiments in which individual gases were injected into the obstructed lung of a dog (i.e., a portion of the lung had been tied off). Absorption was accomplished for carbon dioxide in four minutes, oxygen fifteen minutes, nitrogen sixteen hours and air sixteen hours. As these experiments indicate, nitrogen and air require about the same amount of time for absorption.

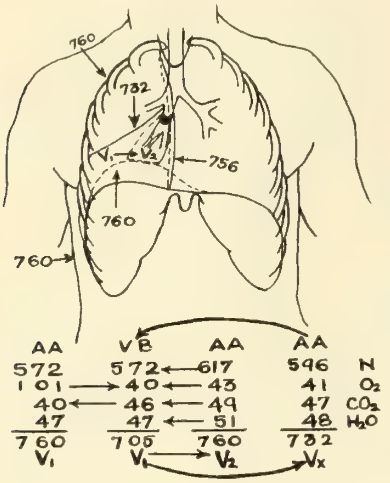

Fig. 2. Absorption of air from an obstructed lobe of the lung and the effect of negative pressure. AA represents the gas tensions in alveolar air and VB the gas tensions in venous blood. When a lobe becomes obstructed exchange of O_2 and CO_2 would take place as indicated between AA and VB. If the volume (V_1) remained unchanged, equilibrium would be established at 705 mm. It would not remain constant, however. It would yield to the pressure of 760 mm. (atmospheric pressure) in the surrounding tissues and shrink to V_2. All of the values would then be too high and gas molecules would pass from AA_1 to VB. If a negative pressure of 732 mm. should develop within the thorax, as a result of shrinkage of the lobe (such pressures have been measured), then there would be further shrinkage in volume until the pressure within the lobe was also 732 (Vx). The gas tension would still be somewhat above venous blood and would move from AA_2 to VB. Equilibrium would not be possible unless the negative pressure within the thorax should drop to 705 mm. (venous blood) or below. If the intrathoracic pressure should remain above 705 mm., theoretically absorption could be complete.

Attempts were made to compare the absorption rate from the lung with that from the anterior chamber of the eye. The volume of the anterior chamber of the eye has been estimated to be about 1/20,000 of that of the lungs. The volume of blood flowing through the lungs at rest is estimated at about 4,600 c.c. per minute; through 1/20,000 part of the lung, this would be 230 cubic millimeters. The rate of circulation of aqueous through the eye is unknown; measurements have been variable (from 2 to 40 cu. mm./minute) but even the maximum would be only a small fraction of the 230 cu. mm. in the lungs. There are several other factors which make comparison difficult. Although there is no interposing membrane between the bubble and the aqueous in the eye, the bubble is all in one mass and exposes the minimum of surface for absorption, whereas an equal volume of air in the lungs is divided into hundreds of little spheres, each of which is surrounded by blood flow, presenting an area of about 500 square centimeters. In the aqueous, there are no blood cells to aid in the quick pick-up of the gas molecules, as there are in the blood surrounding the alveoli. It is difficult also to compare the time of absorption in the sinuses and ear with that in the lungs; in the former the air masses exhibit a small area for absorption compared with the latter. Moreover, the blood flow is only a small fraction of that in the lungs and the interposing membranes are very much denser and thicker. If sixteen hours are required to absorb a volume of air from an obstructed lobe of a lung, probably several days would be required to absorb an equal volume from an obstructed sinus.

To summarize, air injected into the anterior chamber of the eye absorbs completely, but the time is comparatively long; it takes four to five days to absorb 0.1 c.c. It requires several days for air to be completely absorbed from the pleural cavity or the subcutaneous tissue and several weeks from the peritoneal cavity. The only experiments bearing directly on the time factor in the case of the lungs, which I have seen reported, are those by Coryloss and Birnbaum, where sixteen hours were required to absorb air from the normal lung of a dog. These facts concerning the time of absorption would seem to indicate that some factor in addition to absorption is acting in the removal of air in postoperative atelectasis, which develops very promptly after operation.

In all of the articles in the literature on postoperative atelectasis, the matter of ciliary action is almost entirely overlooked. It seems to me that ciliary action cannot be ignored in the respiratory tract any more than heart action can be disregarded in the circulation or peristalsis in studying the physiology of the gastrointestinal tract. There is no evidence that ciliary action in postoperative atelectasis is subnormal.

Some years ago I performed some experiments on the tracheas of freshly killed hens for the purpose of determining a possible relationship between ciliary action and postoperative atelectasis. If an occluding mass of mucus is introduced into the lower end of such a trachea, it will pass through to the upper end by ciliary action in the course of a few minutes. In these experiments the lower end was connected to a water manometer immediately after introducing the mucus; as the mucus advanced toward the laryngeal end, by ciliary action, a negative pressure developed rapidly, reaching a maximum in less than twenty minutes. This experiment was done on nineteen tracheas with the same result in all. The recorded negative pressures varied from 5 to 40 mm. of water.

In order to be certain that this phenomenon was not due to absorption of oxygen in the fresh tissue, another series of experiments was performed connecting the laryngeal or upper end of the trachea to the manometer. In each of these instances a positive pressure developed of about the same magnitude, namely up to 40 mm. of water. Having in mind the probability that many masses of mucus in the longer tubes of a patient suffering from atelectasis might produce a cumulative effect, resulting in a higher pressure, another series of experiments was performed.[8] Three, and sometimes four, tracheas were arranged in tandem and each was connected to a water manometer at its upper end. Connections which could be opened and closed at will joined the tracheas so that the pressure resulting in each could be individually measured, and, when desired, all of them could be connected as a single tube and the cumulative pressures recorded. These experiments demonstrated clearly that the effect is cumulative and pressures as high as 150 mm. were obtained in this way. This is comparable to the pressures measured in postoperative atelectasis.

Several series of experiments were done on the frontal sinuses of dogs. In the first of these, two needles were forced into the frontal sinus of an anesthetized dog, one was connected to a water manometer and through the other a quantity of mucus was injected. A negative pressure began to develop after a few minutes, reaching a maximum in about twenty minutes; some of these pressures were as high as 60 mm. of water. In order to rule out the factor of absorption, a second series was done in which the dog was bled to death through the femoral artery in the middle of the experiment, and then decapitated. Neither procedure caused any significant variation in the pressure. Still other experiments were done on the decapitated heads of freshly killed dogs. These recorded the same phenomenon of a rapidly forming negative pressure.

These experiments on the trachea of the hen and the sinus of the dog demonstrate another mechanism for the removal of air and the development of negative pressure. It is essentially a piston-cylinder action motivated by ciliary power, the masses of mucus acting as the pistons. If this factor is acting in the development of postoperative atelectasis, we would have the explanation for the failure of the soft mucus to slide into the area of negative pressure and for the seeming inaction of the cilia. When the cilia have pushed the masses of mucus up a bronchus as far as they are able, against atmospheric pressure, the mass of mucus becomes stalled. This explains the fact that very soft mucus can seemingly act like a cork; the cilia are holding it in position and attempting to push it further. The negative pressures of 200 to 400 mm. of water, which have actually been measured in postoperative atelectasis, might readily be explained on the basis of a series of mucus pistons in tandem being pushed upward in the bronchial tree by ciliary action. This negative pressure could, theoretically, be produced entirely by ciliary action independent of absorption. The negative pressure is probably maintained by ciliary power only.† One can say that the effective power of the cilia equals the atmospheric pressure minus the pressure in the affected lobe and is the magnitude of the negative pressure. This pumping action of the ciliary mechanism is similar in principle to that of a mercury vacuum pump.

---

†There is another mechanism possible which should be mentioned. If the occluding mucous piston occurs in a membranous bronchus, it is quite possible that the bronchus may collapse behind the piston, due to the negative pressure. If this were to happen, the apposing walls of the bronchus might adhere together because of the cohesiveness of the normal mucous film. In this case, the atelectasis might conceivably be maintained without the presence of an abnormally great quantity of mucus.

It was found in the experiments on the trachea of the hen that if the procedure were carried on for an hour or more the cilia continued to whittle away at the periphery of the mucus piston, gradually carrying it upward and depositing it at the end of the trachea. Theoretically, the cilia could remove the piston maintaining the negative pressure in atelectasis also, if given sufficient time, provided no more mucus formed. However, if production of excessive mucus should continue, then the atelectasis might be maintained.

We have spoken of absorption of air from the sinuses as though it were the usual thing for the ostium to be obstructed while the cavity is still full of air. It is more likely that in conditions resulting in vacuum headache the air was initially displaced more or less completely by the first secretion which formed. It seems likely that the heavy mucus, which forms large viscid masses toward the end of an attack of sinusitis, might produce a negative pressure in a manner similar to that in the experimental dogs. This could very readily be the explanation for the clinical condition known as vacuum headache.

This last suggests another possibility for the rapid removal of air from the lobe of a lung in a surgical patient during operation. It is quite possible that the air is largely displaced by a secretion and that a negative pressure soon follows due to ciliary action.

The negative pressure which occurs in the middle ear might very likely be on the basis of ciliary action moving pistons of mucus down the eustachian tube. Repeated attempts to demonstrate it experimentally have failed to date. Just how the air is removed from the middle ear in blockage of the eustachian tube remains an open question.

Summary

The absorption of air from the anterior chamber of the eye, from the sinuses, from the ear and from obstructed portions of the lung follows the principles of well-known laws of physics such as those governing diffusion, solubility, partial pressures and molecular combination. It seems that air can be completely absorbed from almost any space or tissue in the body, such as those just mentioned, as well as the peritoneum, pleural cavity and subcutaneous tissues, provided sufficient time is allowed and provided the space containing the air can collapse. If the space containing the air cannot collapse or can do so only partially, a negative pressure develops, depending upon the gas pressures present in the absorbing fluid.

In postoperative atelectasis, there are at least three mechanisms by which the air could be removed, namely, (1) absorption, (2) displacement by secretion, and (3) the pumping action of cilia and moving masses of mucus. The negative pressure in most cases of postoperative atelectasis is, in all probability, maintained solely by ciliary action. It is probable that the mechanism involved in the pumping action of the cilia and moving masses of mucus is the one which causes vacuum headache and possibly also negative pressure in the middle ear following otitis media.

TRANSFUSION PROBLEMS

R. W. KOUCKY, M.D.
Minneapolis, Minnesota

DURING the past twenty years there has been a remarkable increase in the use of blood transfusions. In one hospital with which I am connected the increase has been exactly twentyfold. There are many reasons for this striking increase. The changes in surgical methods and the improvements in anesthesia together with the development of the antibiotics have made surgical procedures commonplace which a decade ago were rarely done. Generally this type of surgery necessitates the use of a large amount of blood. The introduction of the ACD solution as a preservative permits the storage of blood for periods of about three weeks, and contributes greatly to making blood more available and hence used more often. Probably the greatest factor in promoting the increased use of blood is the safety of the modern transfusion. The discovery of the Rh factor initiated a tremendous amount of research which has for the most part eliminated the frequent and severe transfusion reactions which were so common prior to 1940.

The safety of a transfusion and its frequent use paradoxically creates a problem. The use of blood is so ordinary and so commonplace that there is today a tendency to look upon a transfusion as a benign procedure much like the administration of saline or glucose. A transfusion always carries with it a definite danger. Disrespect for the lethal possibilities involved can and still does lead to tragic results. Let me cite one example.

In one hospital a unit of blood was ready for an eight o'clock operation. However, it was not used, and it was left in the room after the operation was over. The second operation in this room required a transfusion, and when the anesthetist decided to start the blood she picked up the bottle standing on the side table, and over 400 c.c. was administered before she read the label and realized that that blood was intended for the prior surgical patient. We must continuously teach our hospital personnel the tragic results which may come from carelessness and negligence in the use of blood.

Another problem evolves around the question, "Does the patient actually require a transfusion?" Physicians sometimes forget the normal range of hemoglobin. In this section of the country the lower limit of average hemoglobin is about 12 grams. This means that 70 per cent on a 17 gram standard is a low normal. It is very probable that hemoglobin is adjusted by the body to the particular activity and physiology of the individual. A hemoglobin of 13 grams in one individual may be just as normal as 16 grams in another. If blood is transfused into such an individual having a physiologically normal hemoglobin of 13 grams, that blood is an excess and cannot be utilized and will be eliminated by hemolysis.

There is a tendency today to use a transfusion as an accessory to many operative procedures. Individuals undergoing operations of modern magnitude, for example a cholecystectomy, are not necessarily candidates for a transfusion. Prior to the operations, these same individuals, being in good nutrition and having no anemia, could have been used as blood donors and as such would have lost 500 c.c. of blood. Surely in such individuals an operation with a blood loss of 200 to 400 c.c. does not necessitate a transfusion except perhaps for psychological reasons. It would seem that a transfusion is too dangerous to be used as a dramatic accent in the care of a patient or a patient's relatives.

On the other hand, there are occasions where there has been significant or massive loss of blood, and transfusion is the life-saving therapy. When such occasions arise, the treatment with blood must be prompt and must be generous. Administration of one unit of blood over a period of twenty to forty minutes to an invidual bleeding critically is not adequate treatment. Two, three, or four units of blood should be given simultaneously using each arm and leg as portals, or preferably, the blood should be forced in by pressure. When a patient is losing blood rapidly it is probably impossible to replace the blood too fast. Five hundred c.c. of blood can be given by pressure in four to seven minutes. There should be no hesitation in giving two, three or more units in suc-

Dr. Koucky is Medical Executive, Minneapolis War Memorial Blood Bank.

Read at the annual meeting of the Minnesota State Medical Association, Duluth, Minnesota, June 13, 1950.

cession as long as there is evidence that the patient is bleeding.

Every hospital should have available in surgery, in obstetrics, and in its supply room the equipment for giving blood under pressure, and everyone should know how to use it. Most of the commercial companies handling transfusion equipment now have such pressure sets for sale, and their people are happy to give instructions as to its use and the precautions to take.

In hospitals without a large blood bank, the selection of the kind of blood to use during an acute emergency presents a difficult problem. For example, should time be taken to do Rh typing? Today, because of the reliable typing sera now available Rh grouping can be done in a few seconds. It would be a rare situation wherein blood must be given without knowledge of the Rh grouping of the recipient. If the patient is Rh positive, the problem is simple because blood of either Rh type can be given. The question of sensitization to the Hr antigen in Rh-negative blood can be disregarded because of its great rarity. If the patient is Rh-negative and a sufficient amount of Rh-negative blood is not immediately available, it is necessary to pause for a few moments and evaluate the situation. If the patient is a male, the question must be asked, "Has he been transfused before?" If so, he may have been sensitized by this prior transfusion, in which case these questions must be asked: "Is the emergency great enough to warrant taking any chance on a prior sensitization? Can the emergency be controlled by plasma until Rh-negative blood is available?" The physician must balance the urgency against this risk. If the patient is an Rh-negative female, the problem is much more difficult. Because of the very adverse effect on future pregnancies, no female should ever be deliberately sensitized by a transfusion of Rh-positive blood except as a life-saving measure. Any Rh-negative woman who has had children may be sensitized, and if her obstetrical history suggests that she may have had erythroblastotic babies she most likely is sensitized. Transfusion of Rh-positive blood to these sensitized Rh-negative women results in extremely severe reactions with a very high mortality. In all such cases of possible sensitization, plasma must be used until Rh-negative blood can be obtained. Every community should make arrangements so that the Rh-negative individuals in its population are known and have been organized so that they may act as donors for each other in emergencies.

The use of Group O blood as a universal blood for transfusion does carry with it a certain small chance of reaction. An instance of this type was studied recently by Dr. Matson and will be reported in MINNESOTA MEDICINE. However, the incidence of this type of reaction is very small, and a patient's life should never be endangered by hesitating to use Group O blood for other groups and to do so, if necessary, without cross matching. The addition of the Witebsky substance to such Group O blood takes only a few seconds and still further lessens the danger. The material is purified Group A and Group B blood substance. When this is added to Group O blood, the anti-A and anti-B agglutinins are neutralized, making the blood a truly universal blood.

As a general pathologist, I have had contact with transfusion work for many years and I know that we never had such transfusion safety as we now have. Most of this safety is due to the study and research of men who are devoting their full time to transfusion problems. I am sure that the practitioner owes such men considerable gratitude and support.

History of Medicine In Minnesota

MEDICINE AND ITS PRACTITIONERS IN OLMSTED COUNTY PRIOR TO 1900

NORA H. GUTHREY
Rochester, Minnesota

(Continued from September issue)

Seth (Septimus) Watkins Gould (1847-1891), a native of Canada, was a resident of Olmsted County the greater part of the time from about 1873 into 1891. There is some evidence that he was in Oronoco, this county, in 1873, and that during 1874 he was in Zumbrota, Goodhue County. He probably came to Rochester in 1875, for on April 21, 1876, the Rochester *Record and Union* stated that Dr. Gould, who for some time had been associated with Dr. W. W. Mayo, had gone to reside and to practice medicine in Mazeppa, Goodhue County. In July, 1880, well liked, considered to be a capable practitioner, he returned from Mazeppa to Rochester, again to be an associate of Dr. Mayo. The agreement between Dr. Mayo and Dr. Gould was dated July 24, 1880, and was witnessed by William J. Mayo and W. Logan Brackenridge. It was stated in the newspapers at that time that Dr. Gould was a graduate of Rush Medical College, class of 1866, and that in addition to the duties of an associate physician he would have charge of all patients requiring the services of an electrician, that he had made a successful study of electrical therapeutics. The first official register of physicians of Minnesota (1883-1890), however, listed Dr. Gould as a graduate of the Bennett Eclectic Medical College of Chicago in 1870; he was licensed in Minnesota on December 31, 1883, when he received state certificate No. 665 (E).

During his second period of practice in Rochester, it is said, Dr. Gould was married to Miss Oaks of that place. From May, 1881, until late December, 1881, when he removed to Pleasant Grove, he was secretary of the Rochester Board of Health, during the presidency of Dr. E. W. Cross. In Pleasant Grove Dr. Gould bought the property of a Mrs. Hill, established a drug store and entered his final practice of medicine. His professional contemporary in the village was Dr. Alonzo W. Hill, who practiced there from 1878 to 1889.

On January 1, 1886, Dr. Gould, thirty-nine years of age, was committed by his wife to the Second Minnesota Hospital for Insane at Rochester. The origin of his illness was ascribed locally to sunstroke suffered while working over a gun during his military service (reputedly as a lieutenant during the Civil War), and it was said that a second soldier, working with him, also succumbed to sunstroke and became insane. Dr. Gould died in the state hospital on October 27, 1891, from "general paresis with asphyxia," and was buried in Oakwood Cemetery, Rochester.

Christopher Graham (1856-   ), venerable physician emeritus of Rochester, a practitioner of medicine from 1894 to his retirement in 1919, arrived in Olmsted County early in July, 1856, when he was three months old.

The sixth of the thirteen children of Joseph Graham and Jane Twentyman Graham, he was born on April 3, 1856, near Truxton, Cortland County, New York. His parents were natives of Cumberland County, England; Joseph Graham was born near the village of Dalston, Jane Twentyman in Great Orton Parish. The Twentyman family came to America in 1840; Mr. Graham came in 1844 when he was twenty-two years old. Mr. and Mrs. Graham were married in Cortland County in 1847 and lived there until May, 1856, when with their six small children and a few worldly goods in a horse-drawn wagon they started for Minnesota. Although heavy rains forced them to take a boat from Buffalo to Milwaukee, they finished their journey by wagon into Kalmar Township, Olmsted County, and there founded a new home about five miles northwest of Rochester. After forty years at Grahamholm, which they had first called "The Willows," they removed to Rochester to spend their last years. Their thirteen children were: Mary Elizabeth, William Beck, Thomas Chambers, John, Manfred Davis, Christopher, Joseph, Dinah Frances, Margaret Anne, Frank Charles, Edith Maria, Arthur Frederick and Jennie. In 1949 there were living, Joseph Graham, on a farm near Stewartville, and Dr. Christopher Graham, of Rochester.

The story of the Graham family should be chronicled as a saga and the group commemorated for intelligence, fortitude, integrity and good citizenship. Under the severest hardships of pioneer days parents and children surmounted lack of means and opportunity. Joseph Graham was a kind father, although a strict disciplinarian in the home, and an indefatigable worker who had unusual capacity for taking pains. Jane Twentyman Graham was a woman of rare courage, deep religious faith, warm sympathy and a natural talent for soothing the sick and making them comfortable. Always giving, never asking, as since has been said of her physician son, she nursed without material recompense all in her vicinity who needed her. Perhaps she gave greatest aid in obstetrical cases, in which her knowledge and skill were equal to those of most physicians of the day. In later years her children estimated that she aided in the birth of 243 babies, without medical counsel and without loss of a mother or a child. Two of her daughters, Dinah Frances and Edith Maria (Mrs. Charles H. Mayo) inherited her natural ability in nursing; Dinah Frances, the elder, in her early teens helped her mother in cases of all types. Both of these daughters received accredited training and followed the profession of nursing before marriage. Edith Graham was the first trained nurse in Rochester.

It will require an abler pen and a more suitable vehicle than the present to portray rightly the life of Christopher Graham. Under conditions so difficult that today they are hard to picture, he obtained his education by patient, persistent effort. Until he was twenty years old he worked on the home farm, as did his brothers and sisters, and received only the teaching available in the local district school during terms of a few weeks at most. Books were few, money was too scarce to buy them, and sense of responsibility forbade borrowing them. In the winter of his twenty-first year "Kit" Graham achieved four continuous months of study at the private school of Mr. Loofborough, in Rochester; he then had covered approximately the work of the present day junior high school. The next winter he taught district school and in the following year studied a full term of nine months at Niles Academy (The Rochester English and Classical School, staffed by Mr. and Mrs. Sanford Niles and their assistants). The next four years were filled with farm work, rural school teaching and, in spring and autumn, further study at Niles Academy. Always Christopher walked from home to school and back.

In the autumn of 1882, aged twenty-six years, Christopher Graham entered the University of Minnesota as a subfreshman and special student. On arrival, doubtful of his eligibility, he told President William Watts Folwell of his meager schooling and explained that he probably could attend the university only a year or so, that he loved domestic animals and the land and wanted to be a farmer.

President Folwell assured him that his lack of formal preparation was not a drawback, that his age was an advantage. For the ensuing five years he was a student at the university, dropping out frequently to repair his finances. Thereafter, for two school years, from 1887 into 1889, he taught chemistry and natural philosophy at Shattuck School at Faribault. In the autumn of 1889 he entered the class of veterinary medicine at the University of Pennsylvania and in June, 1892, took his degree; it was then that he received the Lippincott Prize, awarded to the member of the graduating class who had attained the highest general average in the course of three years. After one year as veterinarian to the Experiment Station and Agricultural College of the University of Minnesota, he realized that clinical medicine was his true calling, and he returned to the University of Pennsylvania as a medical student. When in June, 1894, aged thirty-eight years, he received his degree of doctor of medicine, he returnd at once to Rochester, to accept the invitation of Drs. William J. Mayo and Charles H. Mayo to join them in practice. These brothers he has credited with giving him encouragement and opportunity.

The following twenty-five years saw his fulfillment as a physician. He was the first to serve as intern in St. Mary's Hospital (opened in 1889) and he became and remained an attending physician. Throughout the years he studied and observed, visiting hospitals and clinics at home and abroad and taking special courses of study, particularly with regard to the blood. In his earlier period he was an obstetrician of ability; today mature practitioners of this specialty who studied as young physicians with Dr. Graham, express their debt to his wisdom and conservatism. Gradually he fixed his chief interest on diseases of the digestive tract and their differential diagnosis and here he achieved his most brilliant success. The papers which he contributed to the medical literature on chronic appendicitis, gastric ulcer and gastric cancer and gallbladder disease retain their value. His paper on disease of the gallbladder, written before the perfection of certain laboratory tests and the initiation of roentgen examination of the gallbladder, is a classic in diagnosis by case history, signs and symptoms. Dr. W. J. Mayo once said of Dr. Graham: "I have never met his equal as an internist and a diagnostician." Senior associates and junior, alike, recall Dr. Graham as at all times modest and unassuming, distinguished for his insight and acumen, sympathy, patience and delightful humor.

Dr. Graham early became a member of the Olmsted County Medical Society (once its president), the Southern Minnesota Medical Association, the Minnesota State Medical Society and the American Medical Association, and was active in them throughout his professional career. Interested in public health and sanitation, he was a member of the state board of health for several years during the administrations of Governor John A. Johnson (1904-1909), and retired from the work only because of professional duties in Rochester. He was appointed associate in medicine with the Drs. Mayo in 1904 and head of the Division of Medicine of the Mayo Clinic in 1914. He was Professor of Medicine on the Mayo Foundation for Medical Education and Research of the University of Minnesota from 1915 until his retirement in 1919. He is a member of the Alumni Association of the Mayo Foundation.

Christopher Graham's love of farming, horticulture and animal husbandry increased with the years, leading him to distinguished achievement and honor in these fields. He was a leader in introducing Orpington chickens into the country, and at one time had flocks of these fowls, black, white, and buff, second to none in the world. He started the development of what was probably the first purebred Holstein-Friesian herd in this part of the state and he became internationally known as a breeder and importer of blooded livestock. For more years than any other person he was a member of the board of trustees of the Holstein-Friesian Association. His scientific contributions have been recorded in the archives of the Minnesota Livestock Breeders Association and elsewhere.

Dr. Graham is a Mason and an enthusiastic member of the Rotary Club. The latter organization, he has said, has helped him more than has any other influence to understand men and to obtain a broad comprehension of social and civic needs and responsibilities. His support of the Olmsted County Fair Association and his generous gifts of real estate to that association and to the city of Rochester and St. Mary's Hospital evidence his constructive interest in public welfare. He is a supporting member of the Calvary Episcopal Church.

On January 4, 1899, Christopher Graham was married to Elizabeth Blanche Brackenridge, member of a family long notable in Olmsted County and the state. Walter Lowry Brackenridge, of Scotch ancestry, a lawyer, came in 1856 from Pennsylvania to Rochester, Minnesota, with his wife, Margaret McC. Logan Brackenridge. The three children of the family were William Logan, Madge and Elizabeth Blanche; the son, who died in 1905, was a lawyer in Rochester; Madge was married to George D. Parmalee.

For many years Dr. and Mrs. Graham have made their home in East Rochester, in the beautiful brick residence, surrounded by parklike grounds, that was built by the Honorable Walter L. Brackenridge in the early seventies. They have two children, Malcolm Brackenridge Graham and Elizabeth Blanche (Mrs. George M.) Lowry, both of Rochester, two grandchildren, Margaret Brackenridge (Mrs. Calvin T.) Slatterly and Louise Lowry, and two great-grandchildren.

The esteem in which Dr. Graham is held by his fellow citizens cannot be measured, but it is indicated by an inscribed scroll that was presented to him on his eighty-fifth birthday on April 3, 1941:

> Diplomate in both veterinary and regular medicine, authority on diseases of the upper part of the gastro-intestinal tract, practical farmer, patron of animal husbandry, public-minded citizen, unannounced doer of good to scores of his fellowmen, on this the occasion of his eighty-fifth birthday, his many friends and townsmen present this scroll in token of affection and esteem.

Charles Topliff Granger (1870-1939) practiced medicine in Rochester, Olmsted County, from 1892 into 1939, with the exception of two years in McGregor, Minnesota, from 1928 to 1930. For thirty-five years he had his office over the Quale Drug store on Broadway.

Born on July 30, 1870, at the farm home of his parents in Cascade Township, Olmsted County, near Rochester, Charles T. Granger was the second son of Abner Granger and Louise Topliff Granger. Abner Granger was the son of Julius Granger and grandson of Seba Granger, who was descended from a Granger who settled in New England long before the American Revolution; Seba Granger removed from Massachusetts to Otsego County, New York, and there established the family home. Abner Granger was married to Louise Topliff, of Otsego County, on February 25, 1867, and in that year came with his wife to Olmsted County, Minnesota, where for many years he was a highly respected citizen and a substantial farmer and pioneer dairyman.

Charles T. Granger received his early education in rural schools and in the schools of Rochester. He spent a year in the medical department of the University of Iowa and two years at the Hahnemann Medical College, of Chicago, from which he was graduated on March 23, 1892. Returning immediately to Rochester, he entered into partnership with Dr. Wilson A. Allen, in offices in the Leland Block, on Broadway. At first he devoted himself to treatment of diseases of the eye and ear, but proceeded soon to the general practice for which he became well known. In the autumn of 1892 Dr. Allen and Dr. Granger established the Riverside Hospital, in East Rochester; this institution functioned three years.

From the summer of 1896 Dr. Granger practiced alone for eight years, extending his practice from the city into the county and adjoining counties, until it became, by 1904, according to the *Rochester Post and Record* of June 24, that year, "probably the largest individual practice of any physician outside the Mayos." In the earlier years, before automobiles, it sometimes required four consecutive days of driving to make his rounds.

In 1904 Dr. Granger took into partnership one of his former students, Dr. George T. Joyce, newly graduated in medicine from the University of Illinois, and like himself a native of Olmsted County. After this association ended, Dr. Granger for many years maintained a corps of assistant physicians, replacing them as, after a year or two of work with him, they went on to independent practice.

In his earliest years as a physician Dr. Granger was active in the Minnesota State Homeopathic Institute. After 1900 he was a member of the Olmsted County Medical Society (its secretary, 1905; its president, 1906-1907); the Southern Minnesota Medical Association, the Minnesota State Medical Association, and the American Medical Association. In 1935 he published in the *St. Paul Dispatch* a series of articles, *The Saga of a Country Doctor,* which attracted much attention. Although he refused the nomination for county coroner on the Republican ticket in 1896, he served from 1894 to 1899 as county physician for the city of Rochester and the townships of Rochester, Marion, Haverhill and Cascade. He was active in the Methodist Church (he later became a convert to the Catholic faith, it is said), and in civic affairs, serving as alderman, alderman-at-large, mayor, president of the city council two terms, and as member of the city library board.

On March 8, 1898, Charles T. Granger was married to Katherine Cornelie, of Minneapolis. Mrs. Granger, a woman of outstanding personality and ability, was a trained nurse who for a year or more had been the supervisor of nursing at the Riverside Hospital. Dr. and Mrs. Granger first lived in East Rochester, later in the southwestern part of the city, in a home known for its gracious hospitality. In 1928 they removed to McGregor, Minnesota, where for two years they conducted their own clinic and hospital. Mrs. Granger died in McGregor on March 7, 1929, survived by her husband and by four children, Louise, Virginia, Charles and Gordon. Dr. Granger was married on May 2, 1930, to Bertha P. Irish, widow of Dr. H. R. Irish, of Forest City, Iowa; Bertha Irish Granger, a former resident of Rochester, was a graduate of the nurses training school, since discontinued, of the Rochester State Hospital.

In 1930 Dr. Granger resumed the practice of medicine in Rochester, limited by his gradually failing health. He died in Rochester on October 4, 1939, at the home of his niece, Ophelia Granger (Mrs. E. D.) Ridgeway, survived by his wife and his four children and by his sister, Kate E. Granger, of Rochester. His brother, the Honorable George W. Granger, a distinguished attorney of this city, had died a few months previously. In an obituary in the *Minneapolis Tribune* of October 6, 1939, Dr. Granger was credited with having diagnosed the first case each of epidemic infantile paralysis, Spanish influenza and pellagra in Minnesota, and the first case of trichinosis in Rochester.

In 1945 there were living of Dr. Granger's immediate family: Mrs. Granger, in Rochester; Louise Granger (Mrs. Edward B.) Lynch, in Minneapolis; Virginia Granger (Mrs. Raymond T.) Busch, in Gaylord; Charles T. Granger, a newspaperman, of Milwaukee, Wisconsin; and Major Gordon A. Granger, United States Army Medical Corps, in England.

Dr. Charles T. Granger is remembered for his keenness, cleverness and social charm, and for certain of his hobbies; namely, his blooded saddle horses and racers of the earlier years, among them Gipsy Wilkes and Kentucky Prince, and his hunting lodge, Granger's Camp, in the beautiful Genoa Woods of Olmsted County, where he was host to his friends among businessmen and physicians of Rochester.

Gertrude Booker Granger (1871-1928) was born Gertrude Booker on March 13, 1871, at Quincy, Olmsted County, Minnesota, the daughter of James A. Booker, a native of Brunswick, Maine, and Jane Short Booker, a native of Waddington, New York. She had four brothers, O. W., Frank Daniel, F. A., and W. Allison Booker. After the death of Mr. and Mrs. Booker, in 1887 and 1889, respectively, Frank Daniel Booker went to Brunswick, Maine, to live with an uncle. He received his education in the East and in 1901, a qualified dentist, graduate of the dental department of the University of Pennsylvania, he settled in Rochester, Minnesota, where for many years he was a leading dentist. The other brothers became farmers of Olmsted County.

Gertrude Booker received her early education in the country schools of Olmsted County and at the Winona High School. In October, 1892, she entered the newly established Asbury Methodist Hospital, in Minneapolis, as a student nurse, and in June, 1894, was graduated. The following September she matriculated in the medical department of the University of Minnesota, from which she received the degree of doctor of medicine in June, 1897. Her license, No. 776 (R), to practice in the state, she received from the Medical Examining Board of the State of Minnesota on June 10, 1897. For the next six months, living in Dover, she practiced medicine in the communities of Dover and Eyota. On January 1, 1898, she joined the staff of the Drs. Mayo, Graham and Stinchfield in Rochester, primarily as assistant to Dr. Charles H. Mayo in the treatment of diseases of the eye, ear, nose and throat; a little later she was given charge of the work on refractions of the eye.

On February 14, 1900, Gertrude Booker was married to George W. Granger, of Rochester, at the home of her brother, F. A. Booker, at Quincy. Mr. Granger, later Judge Granger, as mentioned earlier, was a native of Olmsted County and a brother of Dr. Charles T. Granger; he first was married to Ophelia Cook, a native of Rochester, on June 24, 1896. Mrs. Granger died on April 5, 1898, leaving an infant daughter, Ophelia C. Granger.

After her marriage Dr. Booker Granger managed the dignified home on Third Street, S.W., and carried on her professional work. She was on the staff of the Drs. Mayo until March 1, 1914, when she became a full time health officer in the city of Rochester, again as assistant to Dr. Charles H. Mayo, who since May 1, 1912, had been city health officer. She resigned from public health work after two years to conduct a limited practice as consulting refractionist, with an office on Broadway. In this work she continued until shortly before her death, which occurred at Rochester on July 5, 1928. She was survived by her husband and by relatives in Olmsted County and elsewhere.

Dr. Booker Granger was a member of the Southern Minnesota Medical Association, the Minnesota State Medical Association and the Alumni Association of the Mayo Foundation. A respected citizen of Olmsted County all her life, she possessed the esteem of associates and the many who profited by her skill, and the high regard of friends who were privileged to know her well.

G. W. Green, an eclectic physician, a native of New York born in 1827, came to Minnesota in 1856 because of "a disposition to pulmonary complaint," and settled in Pleasant Grove, Pleasant Grove Township, Olmsted County. He regained his health and, like many of his contemporaries, in addition to practicing medicine ran a general store and engaged in public service. For the term of 1859-1861 he was a member of the Minnesota House of Representatives.

In September, 1861, Dr. Green removed with his wife and four children to Lake City, Wabasha County, where he developed a good practice. It is said that he was briefly in Goodhue County prior to going to Lake City. In 1871 a heavy cold resulted in his prolonged illness, and the summer and autumn of 1872 he spent in California in the hope of improvement. He died on Thanksgiving Day, November 28, 1872, in Lake City. The funeral services were conducted at the Methodist Church, of which he was a member, under the auspices of the local Masonic Lodge.

Stewart V. Groesbeck (1841-1908), an eclectic physician, a native of Otselic, Chenango County, New York, was in High Forest, Olmsted County, the greater part of the time from 1868 into 1872. Earlier, for about a year and a half, into 1865, he had been in Houston County, associated with Dr. P. T. Bowen, who at one time was in Houston. From High Forest Dr. Groesbeck went to Marshall, Minnesota, and thence, after about fourteen years as a citizen and practitioner of some success and importance, he went to Dakota Territory. On June 23, 1887, he received his license to practice medicine in Dakota, having passed the official examination. He was then living in Watertown; by 1906 he was in Spearfish. Later he became surgeon to the National Home for Disabled Volunteer Soldiers at Hot Springs, South Dakota, and he died in that institution on December 31, 1908. He was at the time of his death a member of the American Medical Association.

Biographical notes on Dr. Groesbeck appeared in an article by Eckman, in 1941, on homeopathic and eclectic medicine in Minnesota, and in a paper by Guthrey, in 1945, on the history of medicine in Houston County. Eckman, citing Neill, stated that Dr. Groesbeck in 1871 received a license to practice medicine in Minnesota, and inferred that the doctor had been affected by the Medical Practice Act of March 4, 1869 (soon afterward repealed). Recent information has confirmed this inference: When in May, 1869, the late Dr. David Sturges Fairchild (1847-1930) of Clinton, Iowa, arrived in High Forest with the ink scarcely dry on his diploma from the Albany Medical College, of New York, he found there two physicians, of whom one was Dr. Alexander Grant, well qualified but inactive professionally. The other was an "army doctor," bluff and jovial and popular in the community, who did not possess a record of formal medical study, almost certainly Dr. Groesbeck. Long afterward Dr. Fairchild wrote, in part: "The Medical Practice Act . . . which had created so many vacant places by suppressing the uneducated doctor, was repealed and brought back my predecessor. The doctor . . . who was only theoretically barred from practice, remained in the background and could easily be found. It was humiliating to see a man with no medical training get the patients, but I could only wait." Dr. Fairchild remembered this practitioner as a vender of homeopathic remedies.

(To be continued in the November issue.)

President's Letter

MEDICAL EMERGENCY: WORLD SIZE

With the Korean conflict has come our second world medical emergency in ten years—an emergency of indeterminable length and intensity. What we learned, in the process of discharging our World War II responsibilities, is valuable in assisting us to assume our obligations during this critical period; but the organizational blueprint falls short of 1950 requirements.

As in World War II, a Committee on Procurement and Assignment has been organized within the Minnesota State Medical Association. The committee will work with representatives of the military service in obtaining the necessary number of physicians for duty with the armed forces without inequitable hardship to the communities they serve.

Medical reservists are being summoned by direct call; and the new amendment to the Selective Service Act provides for the induction of men needed in medical, dental and specialist categories. These men, under fifty years of age, will be called initially from the group of ASTP and V-12 students and others deferred to continue their education who have had less than 90 days active service.

But the role of the profession will assuredly not be confined to war service, vital as that duty is. The threat of atomic bombing demands that we become proficient in the care of radiation victims so that a war in our own backyards does not find us hopelessly vulnerable.

Difficult and challenging days lie ahead of us, as we strive to do our part in the prosecution of war without losing our perspective on the continuing problems of America's health.

Nor should we be led, blindly, into a patriotic acceptance of controls that are inconsistent with the freedoms for which the nation is fighting. Certain controls may be necessary, of course, but Americans have built a great nation on the basis of individual responsibility and this same quality of responsibility should be able to carry us through the exigencies of war.

President, Minnesota State Medical Association

CIVIL DEFENSE

IT IS to be hoped that no atom bomb will ever be dropped on any of our cities. We must admit, however, that the greatest danger facing our country at this moment is a concerted attack on our large centers of population by Russian bombers. Incidentally, the airplane is not the only way an atom bomb could gain entrance to the country. Is there anything to prevent the importation of the component parts of an atom bomb through the Russian Embassy in Washington and its assembling at vital points? There is also no reason for expecting any such warning as a declaration of war as a prelude to atom bombing. As an indication that the Russians have bombing our country in mind is the fact that they themselves are preparing defenses against bombing of vital points in their own country. It is argued that inasmuch as the Russians must know we would never resort to bombing unless we had bombs dropped first on us, their defense preparations indicate that at sometime they will drop atom bombs on us.

It seems a foregone conclusion that any defense against Russian airplanes bearing atom bombs cannot be 100 per cent effective. Any defense measures must of necessity be on a national scale, and a large air force strategically placed and ever on the alert must be relied upon to minimize the possible damage. Airplane defense is being supplemented by the construction of radar and control stations. The establishment of local Ground Observers Corps to implement radar and the Civil Air Raid Warning System is in process in the U. S. Minnesota has completed organization of 264 posts in the 35 counties involved and is now field checking for a test to be conducted by the Air Force in November.

When a bomb is dropped, defense methods planned in advance by each locality will be called into play. If a bomb were to be dropped today, we can be sure no one would know what to do and panic would result. It is high time each unit of population, such as a municipality, city and state, make civil defense plans in case a bomb is dropped.

Much progress has been made in organizing for civil defense on a state basis. An office for Civil Defense for Minnesota has been established at 1003 Commerce Building, Saint Paul (Telephone Garfield 7356). Colonel E. B. Miller is Director and David Harrison, Assistant Director. This office deals directly with the elected heads of local governments and encourages municipalities throughout the state to create local civil defense planning bodies to meet disasters in time of peace or war. Some 250 Minnesota municipalities have already organized planning groups and are in various stages of planning. No community is too small to plan because of the possibility of being called upon to contribute individuals and teams in inter-community co-operation. Stricken areas must receive outside help. Local planners should take inventory at once of existing resources of major importance to disaster relief, such as public utilities, alternate routes and means of transportation, emergency shelters, feeding and clothing of evacuated persons, medical, nursing and hospital facilities, fire fighting equipment, policing, first aid, sanitation, availability of plans and blueprints of existing water, gas, power and light facilities. The various agencies which will be called upon to perform certain duties following a bomb explosion should be informed in advance in order to avoid confusion. The medical profession will be called upon, along with other groups, to perform certain duties and should be prepared.

On October 8, 1948, Governor Youngdahl appointed a Civil Defense Commission which included Dr. A. J. Chesley, secretary of the Minnesota State Board of Health, as chairman of the State Health Section of the Civil Defense. This section is made up of the secretaries of the Minnesota State Medical, Dental, Nurses, Hospital, and Pharmaceutical Associations, the Minnesota Veterinary Medical Society and the Minnesota Public Health Conference. The state has been divided into nine District Health Sections which are actually the same as our Councillor districts.

Each Councillor of the State Medical Association is chairman of his District Health Section which includes representatives of the dental, nursing, hospital, pharmaceutical, and veterinary professions and the M.P.H. Conference. It is the function of each chairman to keep in close touch with the chairman of the city and county Defense Councils and the Red Cross in his district. The Civil Defense Councils of the municipalities are responsible for the execution of the general orders of the Civil Defense Director, and the Medical Health Officers of the eighty-seven counties of the state are members of the local councils. The duties of the councils include co-ordination of health and defense activities locally.

On August 31 a short course on Civil Defense was arranged by Colonel Miller at the University which was attended by about 150 individuals, including councillors, health officers, sheriffs and fire department chiefs. The program included: Effects of Shock and Blast and Fire Attacks on Structures; Mob Psychology and Mass Hysteria; Defense against Atomic Weapons, Using the Geiger Counter, et cetera.

This is a good beginning, but there is an obvious need for the medical profession to inform itself not only on the treatment of victims of atomic bombing, but to make plans in each locality for not only the treatment of bomb victims but their transportation and hospital care.

Dr. Jan H. Tillisch, chairman of the Committee on Military Affairs of the MSMA, in his report to the Council emphasized the need for self-education of the physicians and urged that each county medical society arrange a meeting on Civil Defense to be addressed by someone who has taken a short course such as that mentioned. He also recommended the sending of articles on the treatment of bombing victims to the members by the State Association.*

In meeting such a catastrophe as one caused by an atom bomb, it is obvious that the American Red Cross is not equipped to handle the situation alone. While it functions well in case of floods, tornadoes, fires, earthquakes and epidemics, the Red Cross is too limited in funds to assume large responsibilities in war disasters. Because of its experience with the handling of disasters, however, it can give valuable assistance. The Red Cross has agreed to assist in the program of civil defense in training in first aid and in home care of the sick and injured, in providing food and clothing and temporary shelter, and in participating in a war-time nation-wide blood program. Truly, such a catastrophe as one caused by an atom bomb would require the co-ordinated efforts of everyone planned in advance.

SYMPOSIUM ON HYPERTENSION

THE SYMPOSIUM on Hypertension presented September 18-20, 1950, by the University of Minnesota, with the generous financial support of the Mayo Foundation for Medical Education and Research and the Variety Club of the Northwest, passed expectations as far as interest and attendance were concerned. Presented in honor of Drs. Elexious T. Bell, Benjamin J. Clawson and George E. Fahr, the attendance was so great that the Nicholson Hall Auditorium proved inadequate and the main hall of Northrop Memorial Auditorium had to be utilized. An estimated 400 to 500 physicians were in attendance at each session.

The printed program contained the names of many scientists, including physicians and surgeons who have been interested in the subject of hypertension. Opportunity was given for those not on the program to take part in the discussions, and in this group were many whose names are prominently associated with the problem of hypertension.

The various morning, afternoon and evening sessions were presided over by University professors, some located in Minneapolis and others at the Mayo Foundation in Rochester. Doctors Bell, Clawson and Fahr each presided over a session and also appeared on the program.

The dinner in honor of Doctors Bell, Clawson and Fahr was held on the evening of the last day of the session at the Minneapolis Club. Some 150 physicians attended and paid tribute to the retired physicians. Presided over by Dr. George N. Aagaard, Director of Postgraduate Medical Education at the University of Minnesota, to whose efforts the success of the meeting was largely due, the dinner guests were addressed by Dean Harold S. Diehl, Victor Johnson, head of the Mayo Foundation, Dr. Elexious T. Bell and Arthur W. Anderson, president of the Variety Club of the Northwest.

Fortunately, the material presented at the three-day meeting will be published by the University. Although there is general agreement that the cause of hypertension is unknown and there is no general agreement as to the treatment of the disease, a symposium of this sort at which frankness typified the remarks of the speakers offered a fine opportunity for the exchange of ideas. The published proceedings will afford the reader present-day opinions on the subject of hypertension in a condensed form.

*The following two publications are recommended to the profession: Medical Aspects of Atomic Weapons, Supt. of Documents, U. S. Government Printing Office, Washington 25, D. C. (Price 10 cents) and Effect of Atomic Weapons, same address, (Price $1.25) issued in September, 1950.

CORONARY THROMBOSIS IN EARLY LIFE

THERE appears in this issue a report by Drs. Parsons and Heimark on the effect of diet and smoking on the prothrombin blood level of a small number of normal individuals. They report that the prothrombin level is lowered after eating a full mixed meal more than after an all-vegetable meal, and by smoking. The authors are searching for a means of detecting such individuals as may be susceptible to coronary thrombosis at an early age and possibly developing measures for prevention.

The authors present their findings and a suggestion for further study. If their findings are confirmed it would not justify a vegetable diet and abstinence from smoking for everyone. The problem of selecting those most likely to develop coronary trouble would still exist.

A low prothrombin time does not produce coronary thrombosis. This is due to sclerotic changes in the coronary arteries, the cause of which is not known but runs in some families. Just what is inherited is not known. Some have incriminated the handling of cholesterol, but blood levels of cholesterol do not correspond with the ingestion of certain fats. Blood pressures are regulated by reflex nerve impulses. If excessive reflex impulses result in hypertension, what is inherited? And does repeated elevation of blood pressure lead to arteriosclerosis? Should those who show an increased blood pressure on using tobacco refrain from its use because of the danger of developing arteriosclerosis of the coronaries?

The authors believe that the difference in prothrombin levels—that is, the low prothrombin time—is what precipitates the coronary attack. That they have not proven. Do some normal persons have a more marked lowering of their prothrombin time by heavy eating and smoking? If further investigation proves this to be the case, should these individuals be put on an anticoagulant constantly—a rather difficult and costly procedure fraught with some danger? And further, will the maintenance of a normal or high prothrombin time prevent a coronary thrombosis? To advise a patient with evidence of coronary arterial disease to abstain from overeating and tobacco is good advice. Whether individuals likely to develop coronary arteriosclerosis can be identified by their prothrombin-time reactions to eating and smoking remains to be proven. The article is provocative of thought and investigation.

REHABILITATION OF HANDICAPPED CHILDREN

Approximately five to seven out of every 100 children who return to school this fall will have a physical limitation, predicts Dr. Alfred R. Shands, Jr., medical director of the Alfred I. duPont Institute of the Nemours Foundation, Wilmington, Delaware.

In an article published in the August, 1950, issue of *The Crippled Child* Magazine, official publication of the National Society for Crippled Children and Adults, the Easter Seal Agency, Dr. Shands says that few people realize the tremendous number of children with physical limitations. If proper care is not given to these children in their early years, the greater number of them will grow into adult life—handicapped both in mind and body.

As Dr. Shands says, "The great majority of these children must look to the public school system for their education, hence, the importance of every classroom teacher knowing what the problem is and how to meet it."

"If time is taken to analyze the child's defects, and if he is guided accordingly, many times the teacher will undoubtedly be the principal factor in the success or failure of the child's life."

Dr. Shands adds that the classroom teacher who knows which children have physical limitations should find out from the parents what has already been done for them and ask the school nurse and doctor what she can do to aid in the child's rehabilitation.

"The teacher's approach to the child should be one of friendliness, warmth, interest, patience, kindliness, and an honest liking for the child," continues Dr. Shands. "The teacher should understand his handicap, realize what his abilities are, and guide him in the pathway of learning and then see that he has the confidence in himself to successfully carry on in life."

The child must come to the realization that, although life is hard, he must face the world. Dr. Shands points out that the crippled child should be given neither excess sympathy nor pity. As early as possible, he ought to learn to do everything he can for himself, and should not be assisted unless absolutely necessary or ask needless favors of others.

"It is inevitable," concludes Dr. Shands, "that the teacher can be truly effective only if she understands the physical needs of the child and can help him toward the best use of his abilities."

MEDICAL ECONOMICS

Minnesota State Medical Association
George Earl, M.D., Chairman

AMA GETS REPORT ON BRITISH MEDICAL ASSOCIATION CONFERENCE

David Clayton, AMA's London representative, recently reported that the theme of the British Medical Association annual conference was "the ever-present dissatisfaction and frustration felt by the majority of the nation's general practitioners under the National Health Act." Mr. Clayton noted that sixteen resolutions were passed warning the Labour government that if better treatment in remuneration and a decrease in ever-increasing bureaucratic control were not forthcoming, then British doctors should walk out of the scheme in a body.

Mr. Clayton reports that the conference was sparked by a small but extremely vocal body of doctors, the Fellowship of Freedom in Medicine. This group is working hard to try to recover lost ground. Their main line of attack is to "bring before the British public the more flagrant abuses under the scheme, and to keep on plugging away inside the parent body, the B.M.A."

COMMITTEE STUDIES BRITISH MEDICAL EDUCATION

After making a thorough study of the background and evolution of the National Health Service in Great Britain and its relation to medical education there, a special committee of the American Medical Association has submitted its report. The committee, which did its research during December, 1949 and January, 1950, consisted of deans of American medical schools: Harold S. Diehl, M.D., Minneapolis; Loren R. Chandler, M.D., San Francisco; and Stanley E. Dorst, M.D., Cincinnati.

Speaking of the general practitioner and his role in the education picture, the committee reports:

"Even before the National Health Service Act the lot of the general practitioner in Britain was not too happy, and today it is demoralizing. We do not refer to overwork but rather to the fact that he seems destined to a routine life which does not offer the necessary facilities to practice good medicine and which fails utterly to offer the professional incentives which lead to continued growth of the physician. . . . If we really believe that the general practitioner is the 'backbone of medicine,' then let us prepare him for the most difficult task in medicine. After our experience in England, we are confident that this is the most important job facing the medical schools of the United States during the next decade."

The committee report concludes, saying:

"Finally, we would emphasize again the all-important social, economic and geographic background against which British socialism developed. The National Health Service Act is only one facet of British socialism; the welfare state does not exist except as a part of the whole. Furthermore, conditions in Great Britain are so different from those in the United States that it would be folly to contend that what may be necessary for Britain today should be admirable for transfer to the United States. We, fortunately, have the time that is necessary to evolve an adequate medical service for our people without resorting to the centralization of authority in a welfare state."

Takes Stronger View

Taking a more forceful view of the evils evident in European socialism, Dr. William C. Black, former president of the Association of American Physicians and Surgeons, gives first-hand accounts of the detrimental results of the National Health Service in England:

"Stayed in Kenilworth, England for a couple of days. . . . Found out the proprietor of the hotel was an anesthetist—specialist—and had quit a year ago, not because of pay, but because under the regulations of the National Service Act he was not permitted the freedom of judgment and action essential to the best interests of the patient. . . . Rather than do sub-standard work he just quit and now makes a living from the hotel."

This same doctor told Dr. Black, "This Act had the same effect on me, as a physician, as though I had lost an arm or gone blind or developed some other physical disability which would make it impossible for me to do my work properly."

LOBBY INVESTIGATIONS BRING ACID COMMENTS

After Oscar Ewing recently bragged of his right to crusade for Truman's compulsory medical insurance plan, the *Chicago Tribune* reminded its readers that "Ewing is the most vigorous propagandist of the day in the cause of political medicine." Said the *Tribune:*

> "Ewing proclaimed that 'it was not only his right, but his duty' to propagandize in favor of the Truman compulsory medical insurance plan. In this mission he admitted to having the assistance of sixty-five full-time publicity men, paid by the taxpayer."

Magazine Adds Its Voice

Defending the right of the Committee on Constitutional Government to spend $40,000 a month for printing and distributing John Flynn's *The Road Ahead,* the *Saturday Evening Post* avers that the government is the biggest lobby in the country and spends much more than $40,000 to influence legislation. The *Post* quotes Frank Chodorov in Human Events:

> "Peanuts and fiddlesticks. Every hour of the day the agencies of the Government spend more than that monthly average to influence legislation, and the legislation they plug is to lengthen their tenure, increase their appropriations, better their emoluments, strengthen their hold on the public purse. . . . The biggest, more pernicious, most unscrupulous and entirely selfish lobby in Washington is the Government. . . . Its list of contributors includes every man, woman and child in the United States. And yet it has the effrontery to point the finger of scorn at an organization that digs up a piddling $40,000 a month for printing and distribution of literature. . . ."

Suggests a Positive Attack

The *Post* then suggests a more vigorous attack against the aggressions of the Buchanan investigating committee:

> "We challenge your authority under the Constitution, but we are not embarrassed or ashamed of what we are doing. John Flynn's *The Road Ahead* is an angry book, with here and there an excess of zeal, but it does expose the socialist nature of the Fair Deal program, an analysis already accepted by the British Labor Party. If there is any restriction in America on the right of persons, including corporations, to challenge the pretensions of a political group in this country, it hasn't yet been put in the form of law. Until freedom of speech has been outlawed by Congress, we intend to support our ideas by whatever authorities seem to us likely to arouse the people to their danger.
>
> "The only way the battle for a free economy will be won is by forthright resistance in terms that can be understood, not exclusively by demurrers and legal responses and applications for injunctions, important as these are. If the fight can be staged in an arena where people can see what punches are being thrown, free enterprise may have a chance. It certainly has none if its protagonists always make themselves look like bad boys talking their way out of something sly and discreditable."

American medicine has certainly not been one of those "bad boys" in its open battle against the infiltration of political medicine and the remaining gamut of socialistic schemes.

JOURNAL QUESTIONS MORE SECURITY

Now that President Truman has signed the bill promising social security to some ten million more persons and boosted benefits to those already under its wing, the Wall Street *Journal* can only ask, "What security?"

The most that a family can draw is the promised $150 a month for life, after all principal wage earners have retired. And, the *Journal* says:

> "We can hope, too, that the one hundred and fifty dollar bills will fulfill the real promise to these old people, that it will buy for them what they now dream of. We can hope. But in all candor we must say it is a slim hope.
>
> "Before this new $150-a-month level, the maximum for the same family was $85 a month. Five years, ten years ago $85 a month would have bought more security than the $150 will today. At the very best, the raised maximums do no more than catch up with the cheapening of the dollar. To talk about 'increased benefits' in the new law, as the promisers do, is sheer balderdash.
>
> "This time the ink will hardly dry on the new promises before they begin to fade. A hundred and fifty dollars today won't buy what it would have bought last week. And this same government which promises so much is, at the same time, engaged in the same practices—reckless spending and calculated credit inflation—that have in ten years torn the paper dollar in two."

For Instance—

A short, but pointed editorial also appears in the *Journal,* showing by example, the duplication in the numerous bureaus, agencies, boards and committees which carry on the big business of federal government:

> "President Truman will add a 'panel' of three members to the existing Loyalty Review Board. It will not replace the Board, but will have the duty of reexamining

the examination of F.B.I. files by the Board. So the Washington correspondents tell us, on the best anonymous authority they can get. That is to say:

Great fleas have little fleas on their back to bite 'em,
And little fleas have lesser fleas, and so *ad infinitum*.
And the great fleas themselves, in turn, have greater fleas to go on;
While these again have greater still, and greater still, and so on."

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

230 Lowry Medical Arts Bldg.
Saint Paul 2, Minnesota

J. F. DuBois, M.D., Secretary

District Court of Ramsey County, Minnesota, Declares Vitamins to Be Drugs and Medicines
Sale by Grocers and Food Stores Declared Illegal

Re: Milton Culver doing business as Culver's Food Market vs. John Nelson, John J. Pastenacki, Victor E. Feit, J. Norman French, B. A. Deterling and F. W. Moudry (Minnesota State Board of Pharmacy).

In a test case involving the sale of vitamins in tablet, capsule or liquid form, in grocery stores, meat markets, food stores and other similar places, the Hon. Albin S. Pearson, Judge of the District Court of Ramsey County, Minnesota, on August 7, 1950, made an order denying the motion of the plaintiff in the above entitled action for amended findings of fact, conclusions of law, order for judgment or for a new trial. Judge Pearson granted a stay until October 2, 1950, to permit the plaintiff to appeal from the order, or to avail himself of any other legal remedies that he might have.

Mr. Culver, the plaintiff, operating a retail food store in St. Paul, Minnesota, instituted the action against the members of the Minnesota State Board of Pharmacy to have judicially determined the construction and validity of the Pharmacy Act of 1937. The plaintiff alleged that he brought the action for his own benefit and all other retail food stores of the State of Minnesota, similarly situated. The plaintiff alleged that he had a lawful right to sell, in his food store, articles commonly referred to as food vitamins and food supplement vitamins. It was the claim of the plaintiff that such vitamins were sold in the original labeled packages and were for the purpose of supplementing or fortifying the ordinary or usual diet, and that such vitamins were not sold for medicinal purposes or for the purpose of treating or curing any disease of man. The case was tried before Judge Pearson without a jury commencing May 24, 1948. Among the witnesses for the plaintiff were Dr. Bernard Oser, a chemist of New York City, and Dr. Norman Jolliffe, a physician and surgeon of New York City. Among the witnesses for the Minnesota State Board of Pharmacy were Dr. Russell M. Wilder of the Mayo Clinic, Rochester, Minnesota, Dr. Ole Gisvold, Dr. Ancel Keyes and Dr. Raymond Bieter, all of the University of Minnesota, and Dr. Charles Hensel, a physician of St. Paul. Doctors Wilder, Bieter and Hensel testified that vitamins are drugs and medicines. Following the trial the Court permitted each side to submit written briefs outlining their respective positions and setting forth various citations to sustain their respective claims. After thorough consideration of the matter, Judge Pearson, on April 19, 1950, filed the Court's findings of fact, conclusions of law and order for judgment in favor of the defendants.

In his decision Judge Pearson found that vitamins when prepared in tablets, capsules or liquids composed of pure or concentrated vitamins, natural or synthetic, are drugs within the definition of the term "drug" under the laws of the State of Minnesota. The Court also found that such vitamins when offered for sale in the original boxes are not common household preparations sold for nonmedicinal purposes. The Court also found that such vitamins are not harmless proprietary medicines within the meaning of the laws of the State of Minnesota.

Judge Pearson's decision is of the utmost importance, not only to members of the pharmaceutical profession, but to the medical profession and the public generally. The Pharmacy Board was represented in the case by the Hon. J. A. A. Burnquist, Attorney General of the State of Minnesota, and his Chief Deputy George B. Sjoselius.

Surgical Instruments Found in Possession of Albert Lea Man Arrested on Traffic Charge

State of Minnesota vs. Tracy A. King

Early in the morning of September 13, 1950, Richfield, Minnesota, police arrested Tracy A. King, thirty-five years of age, 524 Park Avenue, Albert Lea, Minnesota, on a charge of careless driving. King was driving an Oldsmobile four-door sedan with Minnesota license plates No. 152-808. In the car police found a doctor's medical bag containing numerous surgical instruments, a stethoscope and various medicinal preparations. A receipt was also found made out to "Dr." King. The Minnesota State Board of Medical Examiners was immediately notified by Sheriff Ed Ryan of Hennepin County, and a lawyer for the Medical Board interviewed King. King admitted that he had been representing himself as a doctor; that he had told conflicting stories of having gone to medical schools in Canada and also in Europe. During the questioning, King stated he was born February 2, 1915, at Winnipeg, Manitoba; that he was a Canadian citizen and entered the United States at Noyes, Minnesota, August 15, 1949. He stated that he was a tile setter by trade and had no medical education. He denied that he had actually treated any patients. King stated that his family name was Stroppa, and that he had lawfully changed his name in court at Winnipeg. The matter has been investigated further at Albert Lea, and it has been ascertained that King has an application on file in the District Court there, to become a citizen of the United States. King claimed that he had the surgical instruments and the medicinal preparations in his possession merely for the purpose of "impressing people."

On September 18, 1950, King pleaded guilty in the Municipal Court of Richfield, to a charge of careless driving and was fined $50.00 by Judge Joseph J. Poitras; the fine was paid. The Minnesota State Board of Medical Examiners is continuing the investigation, and anyone who has any information in reference to King, or any of his medical activities, is respectfully requested to communicate with the Minnesota State Board of Medical Examiners at 230 Lowry Medical Arts Bldg., Saint Paul, Minnesota.

Modern public health does not prevent death alone. It also prevents disease. For every life preserved by a tuberculosis program, scores of individuals are saved from invalidism. For every life saved from malaria, hundreds of individuals are maintained as active producers in the population.—*Am. J. Pub. Health,* August, 1950.

Minneapolis Surgical Society

Meeting of December 1, 1949

The President, Ernest R. Anderson, M.D., in the Chair

CONTROLLED RESPIRATION IN THORACIC AND UPPER ABDOMINAL OPERATIONS

JOHN H. GIBBON, JR., M.D.
Professor of Surgery, Jefferson Medical College
Philadelphia, Pennsylvania

THE PREVENTION of pain has become the least important part of modern anesthesia. Similarly, muscular relaxation for abdominal operations presents no problem to the modern anesthetist. With the solution of these two difficulties modern anesthesia is properly concerned with avoiding disturbance of pulmonary and cardiac function. The function of the lungs is, briefly, to provide entry to the body of the oxygen which is required for metabolic processes and to furnish exit for the carbon dioxide which accumulates as a result of these same processes. The function of the heart is simply to move the blood through the lungs and then to all parts of the body so that these fundamental gas exchanges which take place in the tissues can be compensated for by the reverse process in the lungs.

In the present surgical era the diaphragm has ceased to divide surgeons into the two air tight compartments, as it does the organs of the body. Many upper abdominal operations can be performed with greater ease through a thoracic, or a combined thoracic-abdominal incision. It thus becomes a concern of most surgeons to be interested in this important aspect of modern anesthesia, i.e. the maintenance of normal cardiorespiratory function during operations.

In the absence of adhesions between the lung and the chest wall, opening of one pleural cavity results in the collapse of the lung on that side to about one third of its former volume. This is due to the contraction of the elastic tissue of the lungs. If this elastic tissue were not present and the enormous filming surface, forty square meters, were maintained by stiff alveolar walls, as in a marine or rubber sponge, most of the disturbances of pulmonary function which I am about to discuss, would not occur. With one pleural cavity widely opened the respiratory movements do not result in a normal exchange of gases between the alveoli and the outside air. In addition the respiratory movements, which under these circumstances are greatly increased in magnitude, produce movement of air back and forth between the two lungs instead of in and out of the trachea. The oxygen content and tension of the alveolar gases rapidly declines while the carbon dioxide content and tension rapidly increases. The anoxemia and acidosis which occur are rapidly fatal.

Two ways have been proposed to overcome the collapse of the lung when the pleural cavity is opened. One is to keep the lung exposed to pressure slightly below atmospheric. The other is to maintain a pressure within the lungs which is slightly above that of the surrounding atmosphere. To accomplish the former, Sauerbruch,[7] around the turn of the century, constructed a large chamber maintained at an air pressure slightly below atmospheric, in which the surgeon and his assistants operated. The patient's head projected outside the chamber through a tightly fitting rubber collar. This ingenious but cumbersome apparatus was not widely adopted because of its obvious drawbacks. To accomplish the second method of maintaining expansion of the lungs a positive pressure cabinet was devised. This consisted of a box in which the patient's head was placed through a snug rubber collar which fitted around the neck. The air pressure in this box was maintained slightly above that of the atmosphere. Samuel Robinson[5,6] of Boston, between 1900 and 1910, demonstrated the efficacy of such a positive pressure cabinet in animal experiments and devised one for use with human patients. A simpler method of maintaining positive pressure by the use of a tightly fitting face mask soon replaced the more cumbersome positive pressure cabinet.

Stimulated by Chevalier Jackson's development of the bronchoscope, intratracheal tubes in human patients have now been widely adapted for maintaining a positive pressure within the lungs during intrathoracic operations. These intratracheal tubes ensure an adequate air way at all times and permit the aspiration of any material that may accumulate in the tracheobronchial tree. The great value of these tubes has become so well established that their advantages do not need to be stressed here. Some anesthetists employ these tubes for positive pressure by placing a tightly fitted face mask over them. Others draw the outside end of the tracheal tube through a rubber diaphragm in the face mask and then connect the tube directly with the anesthetic circuit. The drawback to either of these procedures is that, with the use of positive pressure, air passes down the esophagus and enters the stomach, producing gastric distention which requires decompression by stomach tube during the operation or postoperatively. An inflatable rubber cuff around the outside of the lower end of the tracheal tube was soon developed to obviate this difficulty. Gentle distention of this rubber cuff produces for all practical purposes an air-tight system between the air in the lungs and that in the anesthesia circuit, without the interposition of a face mask. Such a system is that most commonly employed today for intrathoracic operations. The problem of preventing collapse of the lungs has thus been satisfactorily solved. Adequate ventilation of the lungs still remains a problem.

Even with the lung inflated, it is still necessary for the carbon dioxide, which is given off from the blood in the alveoli, to pass from the alveolar air to the atmospheric air. Similarly it is necessary to provide for constant replacement of oxygen in the alveolar air which is taken up by the blood. Pure physical diffusion of gases in the closed air circuit is not enough. There must be a rhythmic movement of gases back and forth between the rubber bag in the anesthetic circuit and the alveoli in the lungs. With one pleural cavity widely opened the normal action of the muscles of respiration do not produce an adequate exchange of gases between the alveolar air and the external anesthetic circuit. The increase in size of the thoracic cage which occurs with normal inspiration merely results in air passing into the pleural cavity of the opened side of the chest, with relatively small amounts of air entering the lungs through the tracheal tube. Expiration similarly lacks effectiveness.

The lack of effective ventilation was not apparent at first, because by the use of a high percentage of oxygen in the rebreathing circuit it has been possible to maintain normal oxygenation of blood during the course of prolonged intrathoracic operations. Thus, if ether is the anesthetic agent, and oxygen is used instead of room air, the oxygen tension in the alveoli can be more than quadrupled. Under these circumstances ventilation may be greatly reduced without affecting the oxygenation of the blood. The story however is quite different with carbon dioxide. Here the question is not one of supplying a gas to the alveoli, but of removing a gas from them. Only adequate ventilation can achieve such removal of carbon dioxide. Probably the fact that cyanosis can be avoided by using a high concentration of oxygen in a closed rebreathing system with an open thorax has drawn attention away from the inadequate ventilation which occurs under these conditions. Unfortunately an increase in the carbon dioxide tension of the arterial blood does not produce any change in the color of skin and mucous membranes, as does the accumulation of reduced hemoglobin in the blood. That the ventilation is inadequate under these conditions of positive pressure breathing has recently been demonstrated by Beecher.[1] He has shown that while adequate oxygenation of the blood can be maintained in the course of long intrathoracic operations, the carbon dioxide tension in arterial blood and alveolar air can rise to quite alarming heights with a concomitant profound drop in the pH of the arterial blood.

Some realization that the ventilation is inadequate under these circumstances has led anesthetists to assist the respiratory movements by gently squeezing the bag with inspiration. This increases somewhat the exchange between the alveoli and the external anesthetic circuit. However, even in these circumstancs, Beecher states that he is only able to prevent a rise in the carbon dioxide tension in about one third of his patients. The reason probably lies in the fact that expiration is not assisted in any way; in fact, the pressure in the external circuit with positive pressure breathing increases with expiration, thus hindering the passage of gas out of the lungs into the breathing bag. Thus with positive pressure breathing unassisted by compression of the breathing bag by the anesthetist, the pressure in the rubber bag and hence in the external circuit decreases with inspiration and increases with expiration. These fluctuations of pressure directly oppose the movement of air from the alveoli to the external circuit, and vice versa. By compression of the rubber bag one phase is helped, but not the other.

Stephens et al[8] in 1947, advocated the use of curare in intrathoracic operations and a maintenance of normal ventilation by manual compression of the rubber breathing bag in the closed circuit. If the bag be kept partially collapsed under these circumstances there is no resistance to expiration, and inspiration is effected by manual compression of the bag. If the bag be kept tense, however, ventilation again becomes impaired due to the increase in pressure with expiration. Such manual control of respiration is a tiresome and repetitive task for the anesthetist in operations lasting many hours, and interferes with his other occupations, such as controlling the depth of the anesthesia, taking the blood pressure, recording the pulse rate and supervising the adminstration of fluids.

Crafoord[2] in 1939, advocated the use of a mechanical apparatus for compressing the rubber bag by air pressure to provide adequate ventilation. He stressed the importance of avoiding any resistance to expiration. He demonstrated in dogs that the accumulation of carbon dioxide in arterial blood could be avoided by this means. Mautz,[3,4] in this country, has made a similar demonstration in animals and has developed a simpler apparatus for the compression of the bag in the respiratory circuit by air pressure. Even more recently Mautz has developed a method of direct mechanical compression of the rubber bag.

Using curare and both Crafoord's apparatus and Mautz's machine, in a large series of intrathoracic and upper abdominal operations, we have been impressed with the very adequate ventilation obtained, as indicated by a study of the arterial blood gases in a small series of patients. With a few exceptions the marked increase in carbon dioxide tension and fall in pH, reported by Beecher, has been avoided. The advantages of the use of such a mechanical apparatus over manual compression of the rubber bag may be listed as follows:

1. The ventilation is adequate enough to avoid a profound drop in pH and marked rise in carbon dioxide tension in the arterial blood.
2. The ventilation is continuous and can be easily adjusted as to rate and depth.
3. The anesthetist is relieved from a manual test which is better carried out by mechanical means.

Discussion

DR. RALPH T. KNIGHT: By coincidence, we had chosen the same subject for surgical physiological conference at the University when I learned that Dr. Gibbon was to speak on the subject of the "Physiology of Controlled Respiration." We were, therefore, very fortunate in having Dr. Gibbon discuss the subject with us there this afternoon.

Dr. Gibbon should not apologize for talking on this subject, for these problems of physiology associated with anesthesia must be of deep concern to the surgeon and the more familiar he is with them, the better will be the liaison between the surgeon and the anesthesiologist. I am sure that Dr. Gibbon's visit will further increase the prestige of anesthesiology in this community.

Do you not feel, Dr. Gibbon, that the negative pressure chamber and the positive pressure chamber to which you referred were far less physiologically effective than the intermittent positive pressure as we use it today?

You spoke of the elasticity of the lung creating the problem of ventilation by collapsing the lung when the chest is open. However, this same elasticity helps us in ventilation by expelling the gas each time after we inflate the lung.

You spoke of possible damage to the tracheal mucosa by too much pressure in the inflated cuff on the tracheal tube. We had that happen twice. Dr. Dennis then suggested that we inflate the cuff under control by a water manometer and made the first manometer for us. We now make our own cuffs out of contraceptive condoms. These are large enough in diameter to fill the trachea without stretching the rubber and, therefore, the manometer registers to true air pressure against the tracheal mucosa. We do not use more than 10 mm. mercury or 14 cm. water. However, this pressure in the cuff allows us to expand the lungs up to 10 mm. of mercury pressure with each intermittent expansion. More lung pressure than this blocks the pulmonary capillaries and brings pressure upon the heart, interfering with cardiac output.

Dr. Gibbon has been especially interested in adequate pulmonary ventilation to accomplish adequate elimination of carbon dioxide and to keep the pH of the blood at a normal level. I agree with him completely. It is of special interest to me that he found the Mautz machine with the circle type CO_2 absorber to be the most efficient. We have always believed this to be true.

We believe that a frequent test of the tension of CO_2 in the exhaled gas would help us to regulate the controlled respiration to the proper rate and depth. We have not yet been able to obtain an apparatus which will do this as frequently, quickly, conveniently and accurately as we need. Within a month we are to have a mass spectrometer in the operating room which has been prepared by Dr. Nier in our Physica Department. This will do the job, but the apparatus has cost about $15,000. We hope for a simpler and cheaper method.

Up to now we have depended upon the manual manipulation of the breathing bag to control and augment the respiration. A machine such as Dr. Gibbon has used would be a great physical relief, and we are stimulated to try it to see if it will meet the changing demands of the patient and the situation as well as the manual method. Our surgeons seem to need the lung entirely collapsed much of the time in lung surgery, but inflated often enough to keep it inflatable. In heart surgery, we never cease the manual respiration.

Dr. Gibbon's talk has been an inspiration, and we appreciate it very much.

DR. NATHAN KENNETH JENSEN: I have enjoyed Dr. Gibbon's excellent presentation of this very timely problem. We have all thought of respiration in much too limited a sense, our concern being primarily with pulmonary ventilation in relation to oxygen exchange. Dr. Gibbon's paper this evening graphically illustrates the necessity of also giving serious attention to the requirements of carbon dioxide exchange.

In thoracic surgery, we are frequently harder pressed to meet the requirements of carbon dioxide exchange than of oxygenation. The administration of high oxygen concentration will provide adequate oxygenation with very limited pulmonary ventilation, but there is no way to provide for adequate CO_2 elimination except by maintenance of good pulmonary ventilation.

The problem goes much deeper than this however, as respiration for the tissue cells is dependent upon a bellows, the lungs; a pump, the heart; and a distribution system, the circulation. Failure in any of these results in diminished respiratory exchange with resultant respiratory acidosis and anoxia. The anoxia is easier recognized and we are better equipped to correct it than the hypercarbia. An example is the surgical patient with emphysema and deficient pulmonary circulation. This patient will tax the skill of the most experienced medical anesthetist and still may be in severe respiratory acidosis at the termination of a long surgical procedure.

We have encountered severe diffuse capillary bleeding in several patients with inadequate pulmonary reserve who have slipped into respiratory acidosis after several hours of operating time. I would like to ask Dr. Gibbon if he has noted any tendency in patients known to be in respiratory acidosis to bleed excessively?

DR. CLARENCE DENNIS: In the course of his discussion this afternoon and this evening, Dr. Ralph Knight has pointed out that he felt that sudden emptying of the lungs after full inflation would be a very disturbing thing to a surgeon working inside the chest. Have you noted that the motion of the Crafoord respirator is in fact a source of difficulty in doing surgery with the employment of this machine?

I understand, Dr. Gibbon, that you have done some studies on oxygen saturation with continuous tracings throughout induction and performance of a considerable number of operative procedures. Would it be possible for you to tell us anything of your findings in this regard?

DR. GIBBON (closing): I appreciate very much the remarks of Drs. Knight, Jensen and Dennis. With regard to Dr. Knight's comments, I certainly agree that intermittent positive pressure when the thorax is widely opened is more physiologically effective as regards ventilation than the older negative or positive pressure chambers. It is quite true that the elasticity of the lung helps ventilation by aiding expiration with the thorax open. One should remember, however, that this elastic tension is very slight, being equal to the normal negative intrapleural pressure. Consequently the rubber rebreathing bag should not be kept distended as this will interfere with expiration. Dr. Dennis's manometric control of the air pressure in the inflated cuff of the tracheal tube is an excellent one, and should be widely adopted. If the tension of carbon dioxide in the exhaled gas could be rapidly and simply determined during the course of prolonged intrathoracic operations, it would of course be of great assistance in avoiding respiratory acidosis. I trust

Communication

PARATHION POISONING

To the Editor:

Parathion (O,O-diethyl O-p-nitrophenyl thiophosphate) has proved so highly efficient as an insecticide or pesticide that its importance economically is apparent and its usage is rapidly becoming widespread in agricultural communities. Unfortunately parathion is highly toxic for man as well as for insect life. It may be handled and applied safely if, and only if, stringent precautions are strictly observed. However, in spite of the emphasis placed on the need for such precautions excessive absorption may occur through relaxation of these precautions or through accidental heavy exposure. Physicians may therefore be confronted with cases of poisoning from this compound. The management of acute poisoning by a cholinesterase inhibitor is a medical emergency of a type seldom if ever up to this time encountered in medical practice. The following summary of information now available should therefore be of interest to physicians. From this it will be apparent that in this medical emergency the proper timing and dosage of the antidote atropine may be life saving.

The systemic effects of parathion are qualitatively similar to those of other cholinesterase inhibitors, and to the effects of the acetylcholine analogues (pilocarpine, muscarine, arecoline, mecholyl, doryl). Effects of parathion are interpreted as the result of accumulation of endogenous acetylcholine at synapses of the nervous system. They include giddiness, headache, nausea, vomiting, abdominal cramps, diarrhea, miosis, sweating, salivation, lachrymation, confusion, weakness, and muscular fasciculations. A sense of tightness is felt in the chest as the bronchi constrict and fill with mucus. Fatalities appear to result from constriction and secretions in the bronchi or arrest of the heart. On the other hand, recovery from the acute poisoning is usually complete and uneventful. There has been no evidence of permanent injury in such cases.

Treatment may be effective if atropine grains 1/100 to 1/50 (0.65 to 1.3 milligrams) is given at once and every hour or oftener as needed to keep the patient fully atropinized (mouth dry, pupils dilated). If the lungs have filled before the atropine takes effect, clear the bronchi by postural drainage. Oxygen is then indicated. Morphine is contraindicated. Muscular fatigue and weakness may reach a degree requiring artificial respiration. Following even mild symptoms no additional exposure to parathion or other phosphateesters should be allowed until time for cholinesterase regeneration has been allowed.

Intoxication by parathion or other CE inhibitors is an acute episode of 24 to 48 hours. It is terminated by cholinesterase regeneration and is followed by period of gradually decreasing susceptibility to small exposures. Successive parathion exposures may deplete cholinesterase reserves progressively and create a susceptibility to small doses of tetraethyl pyrophosphate or vice versa. Since CE is regenerated rather slowly in man, patients who have suffered parathion poisoning should not be permitted to experience further possible exposures to this compound until it has been established that CE blood levels have returned to normal. Parathion and other phosphate insecticides are not locally irritating, but they produce local cholinergic effects. There has been no chronic or cumulative action other than that on CE as previously described. Dangerous parathion residues have not been detected on food crops sprayed at the proper stage before harvest.

Very truly yours,
AMERICAN CYANAMID COMPANY
D. O. Hamblin, M.D.
Medical Director

MINNEAPOLIS SURGICAL SOCIETY

(Continued from Page 1033)

that Dr. Knight's efforts to accomplish this will prove fruitful.

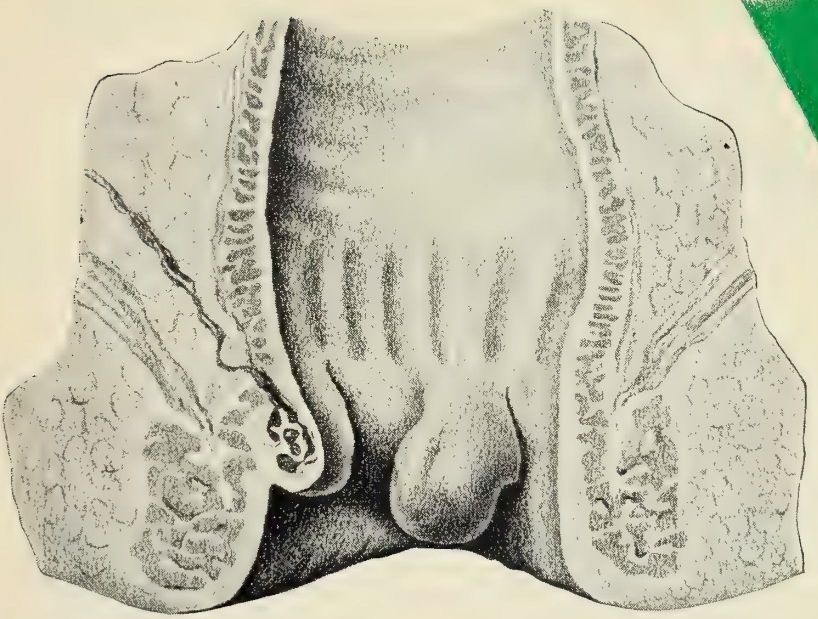
With regard to Dr. Jensen's question concerning profuse capillary bleeding with respiratory acidosis, I might state that we have not made this observation. However, as I stated earlier, we have been able to avoid any serious respiratory acidosis by using mechanical ventilation of the lungs during prolonged intrathoracic operations.

Finally, with regard to Dr. Dennis's questions, I would like to say that we have had no difficulty whatsoever from motion of the lungs using the Crafoord or the Mautz type of mechanical insufflation. With the gentle insufflation pressures used, it is a simple matter to pack the lung out of the way with a moist gauze swab. At intervals during the operation the pressure of the swab is released, and atelectatic portions of the lung are allowed to reexpand. As Dr. Dennis says, we have made some continuous tracings of the oxygen saturation of the blood, using an improved form of the Milliken oxymeter devised by Dr. B. J. Miller of our laboratory. We found little practical use for such continuous recording during the operation but we did learn something, as Dr. Dennis suggests, concerning the induction phase and also concerning the changes which occur in the immediate postoperative period. Because of a momentary period of rather marked unsaturation of blood with oxygen which occurs when sodium pentothal is used to induce anesthesia before introduction of the intratracheal tube, we have discontinued this practice. We now routinely insert the intratracheal tube under local anesthesia, and then with the tube in place we induce anesthesia with a small dose of sodium pentothal continuing with ether and oxygen. Using this procedure we have no period in which the arterial blood is inadequately saturated with oxygen. We have also learned that in the immediate postoperative period, when the patient begins to breath room air, the arterial oxygen saturation tends to decline. This has taught us that it is advisable in patients with poor respiratory reserve to continue the administration of oxygen in the immediate postoperative period until the patient has been returned to his bed and placed in an oxygen tent.

I appreciate the honor of having been invited to speak before the Minneapolis Surgical Society. It has been a great pleasure to be here.

The meeting adjourned.

WILLIAM H. RUCKER, M.D., *Recorder*



Bowel Regulation in Hemorrhoidal Conditions

When there is a tendency toward hemorrhoids, when hemorrhoids are present or after hemorrhoidectomy—when avoidance of straining is desired—Metamucil's smooth, demulcent action conforms to accepted bowel management.

Metamucil softens the fecal content, stimulates peristalsis by supplying plastic, bland bulk and encourages easy, gentle, regular evacuation without irritation or straining.

Metamucil is the highly refined mucilloid of Plantago ovata (50%), a seed of the psyllium group, combined with dextrose (50%) as a dispersing agent.

Woman's Auxiliary

AUXILIARY MEMBERS URGED TO VOTE

Mrs. L. R. Scherer Legislative Chairman

All members of the Woman's Auxiliary to the Minnesota State Medical Association are urged to vote in the November elections. Auxiliary members, as individuals, should support and work for individual candidates.

For information about any candidate, write to Mrs. L. Raymond Scherer, 1930 Irving Avenue South, Minneapolis.

Also of help in keeping Auxiliary members informed will be the radio programs soon to be released by the American Medical Association.

BULLETIN SUBSCRIPTION CALLED IMPORTANT

Mrs. Peter S. Rudie, Bulletin Chairman

The RIGHT and WRONG questions about *The Bulletin* of the Woman's Auxiliary to the American Medical Association:

It is RIGHT to subscribe to *The Bulletin* because:

1. It is to the Auxiliary member what *The Journal* is to the doctor.
2. It contains valuable information on present-day problems of concern to the medical profession and the auxiliaries.
3. It tells of activities of all the auxiliaries in the United States.
4. It is helpful to auxiliaries because it gives new ideas for taking part in public health, health education and public relations activities.
5. Every county officer and auxiliary member should subscribe to *The Bulletin.*

It is wrong:

1. *NOT* to subscribe to *The Bulletin!*

The Bulletin is issued quarterly—August, December, March and May. Subscription price is one dollar a year. Each *Bulletin* Chairman is asking for subscriptions NOW. Names and addresses should be sent in IMMEDIATELY.

PROBLEMS IN TUBERCULOSIS

Even after clinical follow-up in minimal tuberculosis has confirmed the interpretation of the ill-defined x-ray shadow, the physician is faced with another and perhaps more serious problem. He must then cope with the question of the lesion's significance, and must decide upon the course of action to be taken in its management. Will the patient need to undergo hospitalization and surgical procedure? Can the lesion be managed under a home-care regimen? Or will it be sufficient to place the patient under long-term observation, imposing only token limitations upon normal activity? It will be most urgent that these questions be resolved properly and decisively.

These are but a few of the problems which our screening survey experiences in communities and hospitals pose for us and for the medical profession generally. Meeting them directly and fully is the best assurance of effective tuberculosis control.—Robert J. Anderson, M.D., *Journal-Lancet,* April, 1950.

Now Available . . . .

Complete, modern facilities of the Glenwood Hills Hospitals; co-ordinated to give an accurate diagnosis and proper treatment to the neuropsychiatric patient.

These unique facilities include:

- An Outstanding staff of neurologists and psychiatrists
- Electroencephalography
- Electrocardiography
- An ultra-modern laboratory
- A completely equipped x-ray room
- Occupational therapy and Hydrotherapy
- A new physical education department
- Nurses specially trained in our own neuropsychiatric training school

QUOTA FILLED —

For the September class for the School of Neuropsychiatric Nursing. Registration is now open for the January class.

One year course—tuition free

In Memoriam

CHARLES ANTHONY REED

Dr. Charles A. Reed, well known orthopedist of Minneapolis, died August 22, 1950, at Eitel Hospital. He was seventy-eight years of age.

Dr. Reed was born February 2, 1872, at Hastings, Minnesota. He received his medical degree from the University of Minnesota Medical School in 1898. He first practiced medicine at Kalispell, Montana, and in 1903 and 1904 studied orthopedic surgery in Germany. He began practicing medicine in Minneapolis in 1909. In 1920, he helped organize the Nicollet Clinic and became associated with the staff of Eitel Hospital. He held an appointment as associate clinical professor of orthopedic surgery at the University of Minnesota Medical School and was assistant chief surgeon at the Shriner's Hospital for Crippled Children in Minneapolis.

During World War I, Dr. Reed served as a major with Base Hospital 26 in France. He was a member of the American College of Surgeons and a fellow of the American Academy of Orthopedic Surgeons. He was a member of the Hennepin County Medical Society, the Minnesota State Medical Association, and the American Medical Association.

Dr. Reed's wife, the former June Clarke Dickey of Minneapolis, died in 1947. They were married in 1916. He is survived by a stepdaughter, Mrs. S. B. Marantz.

MARK E. RYAN

Dr. Mark E. Ryan of Saint Paul, Minnesota, died following a coronary attack on August 16, 1950. He was sixty years of age.

Dr. Ryan was born at Delafield, Wisconsin, May 4, 1890. He attended school at Oconomowoc, Wisconsin, and obtained a B.S. degree from the University of Wisconsin in 1918. He attended medical school at the University of Wisconsin and at the University of Minnesota, graduating from the latter in 1921. He interned at Cleveland General Hospital in 1921 and began practice in Saint Paul with his brother, Dr. John J. Ryan, in 1922.

Dr. Ryan was a member of the Ramsey County Medical Society, the Minnesota State Medical Association and the American Medical Association. He had been a member of the Ancker Hospital staff for many years and had been active in medical, religious and civic circles in Saint Paul.

Dr. Ryan is survived by his wife, Isabel Perry Ryan; four sons, Mark E., James P., Lawrence P., and Paul W.; a daughter, Sister Mary of St. Mark of the House of Good Shepherd; two brothers, Dr. John J., of Saint Paul, and Dr. William, of Duluth.

The continued responsibility for the care of a chronically sick person adds immeasurably to the education of a physician. It requires maturity to be able to recognize limitations, to avoid becoming angry because the patient does not get well, to avoid becoming discouraged or discouraging, and to continue to wish to help within the limits of one's ability.—JOHN ROMANO, M.D., *J.A.M.A.*, June 3, 1950.

A DISTINGUISHED BAG

with a *Distinguishing* feature

"OPN-FLAP"

HYGEIA
MEDICAL BAGS

. . . it holds ⅓ more!

The famous patented "OPN-FLAP" feature, designed with the advice of physicians, permits opening of Hygeia Bag to the full length and width of top, thus allowing ⅓ more space for packing. Hygeia is the only medical bag that can be packed to the very top and easily zipped closed without crushing or jamming the contents. Made of the finest top grain leathers by luggage craftsmen, the "OPN-FLAP" Hygeia Medical Bag is preferred by doctors everywhere.

Human Back
POSTURE
HEALTH
BLUE PRINTS
BODY BALANCE

Communities throughout the nation are preparing to mark this important event in popular health education. A series of full color posters are nationally distributed in schools, colleges, factories, Y's, clinics, health centers and other institutions. These two heavily illustrated booklets have been widely accepted by physicians everywhere for distribution to their patients. Their titles are: "Blue Prints for Body Balance" and "The Human Back . . . its relationship to Posture and Health." Ask for samples or the quantity you need on your letterhead. Write to SAMUEL HIGBY CAMP INSTITUTE FOR BETTER POSTURE, Empire State Building, New York 1, N. Y. Founded by S. H. Camp and Company, Jackson, Mich.

✦ Reports and Announcements ✦

OMAHA MID-WEST CLINICAL SOCIETY

The Omaha Mid-West Clinical Society will hold its eighteenth annual assembly at Hotel Paxton, Omaha, Nebraska, October 23 to 27, inclusive.

The general program plan for 1950 will be much the same as in previous years. Distinguished guest speakers who are eminent in their particular specialty fields will present addresses, clinics and question-and-answer periods; members of the society will present lectures, panel discussions and scientific exhibits; a guest panel on the antibiotics has been scheduled for Friday morning. Scientific motion pictures will open the daily program, and technical exhibits will again be on display.

The annual sessions of the Omaha Mid-West Clinical Society have received a Class A rating from the American Academy of General Practice. This means that Academy members who attend the sessions will receive credit toward the fifty hours of *formal* postgraduate study required of them every three years.

Further information may be obtained by writing to the executive office of the Society, 1031 Medical Arts Building, Omaha, Nebraska.

INSTITUTE OF INDUSTRIAL HEALTH

The Institute of Industrial Health of the University of Cincinnati will accept applications for a limited number of fellowships which are being offered to qualified candidates who wish to pursue a graduate course of instruction which will qualify them for the practice of industrial medicine. Candidates who complete satisfactorily the course of study will be awarded the degree Doctor of Industrial Medicine. Any registered physician, who is a graduate of a Class A medical school and who has completed satisfactorily two years of residency (including internship) in a hospital accredited by the American Medical Association may apply for a fellowship in the Institute of Industrial Health. The course of instruction consists of a two-year period of intense preliminary training in the basic phases of industrial medicine followed by one year of practical experience under adequate supervision in industry. During the first two years, the stipends for the fellowships vary from $2,100 to $3,000. In the third year the candidate will be compensated for his service by the industry in which he is completing his training. Requests for additional information should be addressed to the Institute of Industrial Medicine, College of Medicine, Cincinnati 19, Ohio.

UROLOGY AWARD

The American Urological Association offers an annual award of $1000 (first prize of $500, second prize $300 and third prize $200) for essays on the result of some

clinical or laboratory research in urology. Competition shall be limited to urologists who have been in such specific practice for not more than five years and to men in training to become urologists.

The first prize essay will appear on the program of the forthcoming meeting of the American Urological Association, to be held at the Palmer House, Chicago, Illinois, May 21 to 24, 1951.

For full particulars write the secretary, Dr. Charles H. de T. Shivers, Boardwalk National Arcade Building, Atlantic City, New Jersey. Essays must be in his hands before February 10, 1951.

POSTGRADUATE CONFERENCE IN OTOLARYNGOLOGY

The annual Postgraduate Conference in Otolaryngology at the State University of Iowa, will be conducted November 27 to December 2 at the University Hospitals, Iowa City, Iowa. Further information may be obtained from the Director of Medical Postgraduate Studies, Medical Laboratory Building, Iowa City, Iowa.

RADIOLOGICAL SOCIETY OF NORTH AMERICA

The Radiological Society of North America will hold its thirty-sixth annual meeting in Chicago, December 10 through 15. Headquarters will be at the Palmer House where scientific and technical exhibits and sessions will be held. All members of the profession are welcome and are invited to attend.

CONTINUATION COURSES

Diseases of the Chest.—A continuation course for physicians in diseases of the chest will be presented at the University of Minnesota Center for Continuation Study, October 26 to 28. The course is intended for general physicians and is presented with the sponsorship and financial support of the Minnesota Trudeau Society. Distinguished visiting physicians who will participate as faculty members of the course include Dr. O. A. Sander, associate in medicine, Marquette University Medical School; Dr. John H. Skavlem, president of the American Trudeau Society, and associate professor of medicine, Cincinnati University Medical School; and Dr. James J. Waring, professor and chief of medicine, University of Colorado. The remainder of the faculty for the course will be made up of members of the staff of the University of Minnesota, the Mayo Foundation, and the Minnesota Trudeau Society.

Child Psychiatry.—A continuation course in child psychiatry for pediatricians and physicians will be presented at the Center for Continuation Study, November 27 to December 1. Dr. Ralph D. Rabinovitch and Dr. John Waterman will participate as lecturers and group discus-

sion leaders. Dr. Reynold A. Jensen, head of the Child Psychiatry Service of the University of Minnesota, is in charge of the arrangements for the course and will also act as lecturer and group discussion leader.

Poliomyelitis.—A continuation course on poliomyelitis will be presented at the University of Minnesota Center for Continuation Study on November 9 to 11, with the sponsorship of the Elizabeth Kenny Institute. The course is intended for doctors of medicine engaged in general practice and for such specialists as pediatricians, physiatrists, orthopedic surgeons, and neurologists. Dr. Harold A. Sofield, associate professor of the Department of Bone and Joint Surgery, Northwestern University Medical School, will be the visiting faculty member for the course.

NORTHERN MINNESOTA MEDICAL ASSOCIATION

Approximately fifty physicians attended the two-day annual meeting of the Northern Minnesota Medical Association in Bemidji on September 8 and 9. The meeting was held under the direction of Dr. W. J. DeWeese, president of the group during the past year.

Officers elected during the business session include the following: Dr. L. W. Johnsrud, Chisholm, president; Dr. G. A. Sather, Fosston, re-elected vice president; Dr. C. L. Oppegaard, Crookston, re-elected secretary-treasurer.

SOUTHERN MINNESOTA MEDICAL ASSOCIATION

At the annual meeting of the Southern Minnesota Medical Association in Mankato on September 11, Dr. R. F. Hedin, Red Wing, was elected president of the organization. He succeeds Dr. Warren E. Wilson of Northfield.

Other officers named at the meeting are Dr. C. W. Rumpf, Faribault, first vice president; Dr. H. G. Nilson, Mankato, second vice president, and Dr. W. A. Merritt, Rochester, secretary-treasurer.

The 1951 meeting of the association will be held in Rochester.

MINNESOTA SOCIETY OF NEUROLOGY AND PSYCHIATRY

The Minnesota Society of Neurology and Psychiatry held its regular meeting in Saint Paul on September 12. Dr. J. C. Michael, Minneapolis, presented a discussion of "Antabus Therapy in Alcoholism," and Dr. Harold F. Buchstein, Minneapolis, spoke on "Prefrontal Lobotomy in the Relief of Pain."

PENNINGTON COUNTY SOCIETY

In the first election of officers conducted by the recently organized Pennington County Medical Society, at a meeting in Thief River Falls on August 23, Dr. O. F. Mellby was elected president of the group. Other officers elected include Dr. Harold C. Johnson, vice president, and Dr. George T. Van Rooy, secretary-treasurer. All are of Thief River Falls.

During the scientific part of the meeting Dr. A. E. Culmer of Grand Forks, North Dakota, presented a paper on the operative treatment of fractures.

RED RIVER VALLEY SOCIETY

The Red River Valley Medical Society held a meeting in Crookston on July 22. Principal speaker at the afternoon session was Dr. Richard E. Reiley, Minneapolis, who discussed fractures and fracture problems as the orthopedist sees them referred by the general practitioner.

A feature of the evening session was a discussion of the Minnesota medical educational campaign by Lyle A. Limond, field secretary of the Minnesota State Medical Association.

WASHINGTON COUNTY SOCIETY

At the regular monthly meeting of the Washington County Medical Society held at Stillwater in September, Dr. Emmerson Ward of Rochester spoke on "Cortisone in Therapeutics." Visitors attending the meeting included Dr. D. A. Burlingame, Saint Paul, Dr. Campbell of New Richmond, Dr. Cornwall of Andover, and Dr. Bourget of Hudson, Wisconsin.

CEREBRAL PALSY CLINIC

The Cerebral Palsy Council, Inc., of Minnesota, 279 Rice Street, Saint Paul, is endeavoring to develop a cerebral palsy registry. Its purpose is to acquaint families of these persons with groups in various vicinities who are studying the problem. Registry cards were sent out last spring to secretaries of all county medical societies. Secretaries are urged to return these cards with necessary information on each as quickly as possible.

SALT WATER ORALLY FOR SHOCK

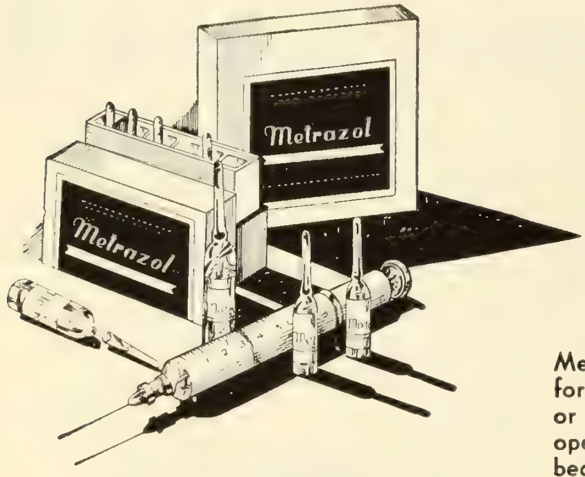
A group of leading American surgeons has advised the Public Health Service, Federal Security Agency, that salt water taken by mouth, in a vast majority of cases, is as effective as blood plasma in the emergency treatment of shock from serious burns and other injuries.

The recommending surgeons are members of the Surgery Study Section, an advisory body to the National Institutes of Health and to the Surgeon General of the Public Health Service.

In general terms, the treatment calls for approximately one level teaspoonful of table salt and one-half teaspoonful of baking soda for each quart of water. A number of quarts are required each day. The only limitations on the amount consumed is the ability of the patient to consume the saline solution. Since great thirst accompanies serious burn injury, it has been found that patients will voluntarily consume a sufficient amount of the solution, which is quite palatable. No other drinking fluid is permitted in the first few days following injury.

In releasing the recommendation, Surgeon General Leonard A. Scheele said:

"Salt water offers an easy, practical method for the treatment of shock which follows serious burns and other injuries. It is particularly important in any period of large scale disaster. Unless the patient is disoriented, is in acute collapse or is among the very small percentage who become nauseated by drinking large quantities of the salt solution, the sodium chloride formula will be effective when administered by mouth."



Metrazol, pentamethylentetrazol
Ampules, 1 cc. and 3 cc.
Sterile Solution, 30 cc. vials
Tablets and Powder

Metrazol

COUNCIL ACCEPTED

A DEPENDABLE, QUICK-ACTING CEREBRAL AND MEDULLARY STIMULANT

Metrazol is indicated for narcotic depression, for instance, in poisoning with barbiturates or opiates, in acute alcoholism and during the operation and postoperatively when respiration becomes inadequate because of medullary depression due to the anesthetic.

Inject 3 cc. Metrazol intravenously, repeat if necessary, and continue with 1 or 2 cc. intramuscularly as required.

Service while it's hot!

GE MOTTO!

And that's exactly what we mean. GE X-Ray service is on the spot as soon after your S O S as we can get to your office.

Take for instance the fire that put the x-ray department of a Long Island hospital out of commission . . . damaging beyond repair their diagnostic x-ray panel. Prepared for any contingency, the hospital pressed a mobile unit into action and called GE X-Ray service.

It took all night and two crews of servicemen to do it, but by dawn — the hospital's x-ray department was back in full operation.

This story is typical of the hundreds of documented GE service reports in our files. A service which proudly lends a new, broader conception to the guarantee that stands back of every GE installation.

◆ Of General Interest ◆

Dr. John F. Pohl, Minneapolis orthopedic surgeon, is the author of a recently published book entitled "Cerebral Palsy." The book, which is said to be the first complete medical text on cerebral palsy, was published by the Bruce Publishing Company, Saint Paul and Minneapolis.

* * *

Dr. Titus C. Kreuzer, of Marshall, who recently returned from a several months' tour of Europe, writes that there was a considerable difference of opinion in England concerning the national medical service. "It was very definite," he writes, "that the working class seemed to be in favor of the 'free medical care,' as they called it, because it didn't cost them anything. However, the white-collar class was very bitter about the plan, stating that they had always been able to care for their own needs and could continue to do so. They said they did not want to get into the queue but wanted service when they needed it."

Dr. Kreuzer adds that "in Germany, Italy and France it was very evident that a preponderance of the lay people, as well as physicians, wanted to get to America if possible."

* * *

Dr. Conrad I. Karleen, formerly associated with Dr. Carl W. Waldron of Minneapolis, has announced the removal of his office to 402 Medical Arts Building, Minneapolis. His practice is limited to plastic and reconstructive surgery.

* * *

Dr. William H. Inglis has joined the staff of the Dr. R. J. Cairns clinic in Redwood Falls. Dr. Inglis was graduated from the University of Minnesota Medical School in 1949.

* * *

Red Lake Falls acquired a new physician in August when **Dr. Allan McKaig** arrived from Birmingham, Alabama, to be associated in practice with Dr. Lester N. Dale. A graduate of the University of Syracuse, Dr. McKaig spent two years in the armed services and then practiced at Birmingham for two years. Dr. McKaig and Dr. Dale will practice in newly remodeled offices in a building which Dr. Dale purchased in August.

* * *

Dr. Kenath Herrick Sponsel has moved his offices to 321 Medical Arts Building, Minneapolis, to continue the practice of the late Dr. Vernon L. Hart. Dr. Sponsel's practice will be limited to orthopedic and traumatic surgery.

* * *

Dr. Valentine O'Malley has opened offices for the practice of internal medicine at 541 Lowry Medical Arts Building, Saint Paul.

Since 1948 the **American Diabetes Association** has conducted and financed a yearly detection drive through its special Diabetes Detection Committee. It is estimated that there are a million unknown cases of diabetes in the country. Early detection means better control and more normal lives for those so afflicted. Last year about 7,500 unknown diabetics were uncovered during Diabetes Week. It is expected that Diabetes Week this year, scheduled for November 12 through 18, will be even more successful.

The American Diabetes Association has prepared a special article designed for use in company publications and those of labor organizations, with the aim of facilitating acceptance of the campaign by employes. Copies of the article may be obtained from the office of the American Diabetes Association, 11 West 42nd Street, New York, N. Y.

The campaign is a program of the medical profession, approved by the AMA, and needs the support of the community. Last year, through the cooperation of the local county medical society and the Chamber of Commerce in Virginia, Minnesota, 9,791 residents of the city were tested and at least fifty new cases of diabetes were discovered.

* * *

Dr. Gordon R. Kamman, Saint Paul, spoke on "Psychosomatic Medicine" at the monthly meeting of the Lyon-Lincoln Medical Society at Marshall on September 19.

* * *

Dr. Harry W. Christianson and **Dr. Robert J. Tenner,** Minneapolis, have announced their association with Dr. Lloyd F. Sherman, who was formerly associated with Dr. Harry E. Bacon of Philadelphia in the practice of proctology.

* * *

The American Dermatological Association is offering a prize of $300 for the best essay submitted on original work not previously published relative to some fundamental aspect of dermatology or syphilology. Manuscripts, double spaced, should be submitted in triplicate not later than February 1, 1951, to Dr. Louis A. Brunsting, Secretary, American Dermatological Association, 102 Second Avenue S.W., Rochester, Minnesota.

* * *

Dr. John S. Hamlon has become a member of the staff of the state hospital at Fergus Falls. A graduate of the University of Minnesota Medical School, Dr. Hamlon served for five years in the Army in Africa and Europe. Following his release from the Army he practiced at St. Charles until his move to Fergus Falls in August.

It was announced on August 24 that **Dr. Joseph C. Belshe** planned to leave Northfield by September 15 to become associated in practice with Dr. Fred B. Riegel at St. Croix Falls, Wisconsin. Dr. Belshe has been associated in practice in Northfield with Dr. Robert F. Mears.

* * *

In August the Clearwater Clinic of Bagley purchased a clinic building at Gonvick and announced that a physician would be secured to replace **Dr. Norman F. Stone,** of Gonvick, who had received orders to report for duty in the Navy. It was expected that Dr. Stone would leave Gonvick about November 1.

* * *

Dr. G. T. Schimelpfenig and **Dr. B. H. Simons,** Chaska, attended a meeting in Shakopee on August 24 at which plans for a tri-county community hospital project were discussed.

* * *

The engagement of **Dr. Jack Gordon Olsen,** formerly of Edina, and Miss Nancy Elizabeth Harris, Durham, North Carolina, was announced on August 27. The wedding is scheduled for October 27. Dr. Olsen is a graduate of the University of Minnesota Medical School.

* * *

The following statement on prophylaxis against subacute bacterial endocarditis was approved at the annual meeting of the **American Council on Rheumatic Fever** on June 12:

Following dental extractions and removal of tonsils and adenoids, bacteria are frequently present in the blood stream for short periods of time. In rheumatic individuals or in patients with congenital heart disease these bacteria may lodge in the heart valves and cause bacterial endocarditis. Although a variety of bacteria cause this disease, the majority of cases are due to alpha streptococci (Streptococcus viridans). Alpha streptococci are usually resistant to sulfa drugs. Penicillin is, therefore, recommended for prophylaxis.

1. Except in emergencies, operative procedures in rheumatic individuals should be deferred until there is no clinical evidence of rheumatic activity and laboratory tests indicate that the rheumatic process is subsiding.

2. Patients should be free of upper respiratory infection.

3. Minimum dosage of penicillin: (a) 300,000 units of aqueous penicillin injected intramuscularly thirty to sixty minutes before extraction or operation; (b) 300 000 units of procaine penicillin in oil injected intramuscularly at the same time in a different site.

Penicillin prophylaxis is not necessary for the extraction of deciduous incisors or bicuspids unless infection of the gum is present. It should be used for the extractions of deciduous molars, all permanent teeth and for tonsillectomy and adenoidectomy. In most instances it is best to extract one tooth at a time; multiple extractions should be avoided. In cases of extensive gum infection or severe root infections (apical abscesses) it is advisable to give several doses of penicillin, starting the day before

operation and continuing one or two days thereafter.

Women with rheumatic or congenital heart disease should receive penicillin prophylaxis at the time of delivery. It is also recommended for patients requiring gastrointestinal surgery.

* * *

Dr. J. J. Ahlfs, Caledonia, has announced that **Dr. Hildegard J. Virnig,** formerly of Mount Morris, Illinois, has become associated in practice with him. A graduate of the University of Minnesota, Dr. Virnig has done postgraduate work in pediatrics and gynecology.

* * *

A chest clinic was conducted in Austin on August 28 by **Dr. Karl H. Pfuetze,** director of Mineral Springs Sanatorium, Cannon Falls.

* * *

At a meeting of the South Dakota Medical Society in Spearfish, South Dakota, during the middle of August, **Dr. William H. Bickel,** Rochester, presented a paper entitled "Acute Fracture Complications."

* * *

Dr. and Mrs. L. R. Parson, Elbow Lake, were honored on the occasion of their thirtieth wedding anniversary at a dinner party given by friends at Sandy Point on August 31.

* * *

Dr. Roger F. Hartwich, who has practiced in Winona for more than a year, joined the staff of the Winona Clinic on September 5.

* * *

Dr. J. Arthur Myers, professor of public health and preventive medicine at the University of Minnesota, left for Rome on September 12 to speak at the first International Congress on Diseases of the Chest. He also was scheduled to lecture at the Hebrew Medical School in Jerusalem.

* * *

Dr. Malcolm J. Lester, formerly of Fairmont, has taken over the general practice of Dr. C. F. Medlin in Truman. Ill health forced Dr. Medlin to retire from active practice.

Dr. Lester, a graduate of the University of Louisville, interned at Swedish Hospital, Minneapolis, then was associated in practice with Dr. Harold Coulter in Madelia. Before moving to Truman he was practicing with Dr. R. S. Hunt and Dr. R. C. Hunt in Fairmont.

* * *

After practicing in Jackson for a year, **Dr. Curtis M. Johnson** left during the first week of September to begin practice elsewhere. Before leaving Jackson, Dr. Johnson stated that his plans were somewhat uncertain because of the changing military situation.

* * *

The offices of **Dr. F. W. Behmler** and **Dr. R. A. Rossberg** in Morris have been completely remodeled and enlarged. The changes were made to provide accommodations for Dr. J. C. Kooda, who, it was

announced, was moving from Eagle Bend to practice in Morris.

* * *

It was announced on August 31 that **Dr. Harold J. Stoen** was planning to open offices for the practice of medicine in Anoka about September 18. A graduate of Rush Medical School in 1934, Dr. Stoen interned at Fresno General Hospital, California, and then completed a one-year residency in surgery at the Home Hospital, Lafayette, Indiana. After three years as a staff member of the U. S. Marine Hospital at Cleveland, Ohio, he began general practice in Lafayette in 1940. With the exception of four years with the Army Air Force during World War II, he practiced continually at Lafayette until 1950.

* * *

Dr. Robert Nash Evert and Miss Doreen Alma Nerlund were married on September 29 in the Como Park Lutheran Church, Saint Paul. Dr. John Evert, the brother of the groom, was best man. The bridegroom is the son of Mrs. John Evert and the late Dr. John Evert of Glendive, Montana.

* * *

Dr. Lawrence J. Swanson has opened offices for the practice of medicine at 950 South Robert Street, West Saint Paul. Dr. Swanson was graduated from the University of Minnesota Medical School in 1946.

* * *

Dr. Alvin Erickson of the Long Prairie Clinic spent two weeks in September at the Cook County Hospital, Chicago, taking postgraduate courses.

* * *

Dr. F. R. Heilman and **Dr. W. E. Herrell,** Rochester, have been named to the editorial board of a new medical journal, "Antibiotics," which will make its first appearance in January. Dr. Heilman is with the bacteriology division of the Mayo Clinic, and Dr. Herrell is with the diagnostic divisions of general medicine and surgery.

* * *

Dr. Frank J. Hill, Minneapolis health commissioner, has been named to the founders group of the American Board of Preventive Medicine and Public Health.

* * *

Dr. Mark Anderson, Jr., Rochester, a fellow in surgery in the Mayo Foundation, reported for active duty with the Navy on September 5. He was the first fellow from the foundation to be called into active service.

* * *

Dr. Evelyn E. Hartman, formerly with the department of baby clinics in Finland, has joined the staff of the Minneapolis city health department to serve as maternal and child health physician.

* * *

Dr. Howard Kaliher left Pelican Rapids late in September to move to Tillamook, Oregon, where he had accepted an appointment to the staff of the Tillamook County Hospital.

An Observation on the Accuracy of Digitalis Doses

Withering made this penetrating observation in his classic monograph on digitalis: "The more I saw of the great powers of this plant, the more it seemed necessary to bring the doses of it to the greatest possible accuracy."[1]

To achieve the greatest accuracy in dosage and at the same time to preserve the full activity of the leaf, the total cardioactive principles must be isolated from the plant in pure crystalline form so that doses can be based on the actual weight of the active constituents. This is, in fact, the method by which Digilanid® is made.

Digilanid contains all the *initial* glycosides from Digitalis lanata in crystalline form. It thus truly represents "the great powers of the plant" and brings "the doses of it to the greatest possible accuracy".

Clinical investigation has proved that Digilanid is "an effective cardioactive preparation, which has the advantages of purity, stability and accuracy as to dosage and therapeutic effect."[2]

Average dose for initiating treatment: 2 to 4 tablets of Digilanid daily until the desired therapeutic level is reached.
Average maintenance dose: 1 tablet daily.
Also available: Drops, Ampuls and Suppositories.

1. *Withering, W.:* An account of the Foxglove, London, 1785.
2. *Rimmerman, A. B.:* Digilanid and the Therapy of Congestive Heart Disease, Am. J. M. Sc. *209:* 33-41 (Jan.) 1945.

Literature giving further details about Digilanid and Physician's Trial Supply are available on request.

Sandoz Pharmaceuticals

DIVISION OF SANDOZ CHEMICAL WORKS, INC.
68 CHARLTON STREET, NEW YORK 14, NEW YORK

Among the speakers at the annual meeting of the Idaho State Medical Association at Sun Valley, Idaho, during the first week of September were **Dr. John S. Lundy** and **Dr. Robert Kierland.**

* * *

Dr. Mitrofan Smorszczok, Polish displaced person who was granted his medical license in Minnesota this summer, began practice in Monticello in mid-August. He is associated with Dr. William E. Hart of Monticello. It was Dr. Smorszczok's arrival in Minnesota in 1948 that started a controversy about the state rules barring foreign-trained physicians from licensure.

* * *

Dr. Leonard M. Ellertson, a graduate of the University of Iowa Medical School, has become associated in practice with Dr. C. E. J. Nelson and Dr. O. A. E. Erdal in Albert Lea. Dr. Ellertson has served in the Navy and has been a resident physician at the Ball Memorial Hospital, Muncie, Indiana.

* * *

Dr. and Mrs. J. F. Weir, Rochester, left during the first week of September for a two-month trip to Europe. In addition to sightseeing, Dr. Weir, who is head of a section in medicine at the Mayo Clinic, attended the First International Congress of Internal Medicine at the University of Paris during the middle of September.

Dr. Hector M. Brown, medical director of the Walker Hospital at Walker, has opened a branch office in Backus for the practice of medicine. The office is open on Saturday mornings.

* * *

After forty-six years of medical practice, forty-two of which were spent in Northfield, **Dr. I. F. Seeley** retired from active practice and moved to Tucson, Arizona, on August 27.

On the day of departure a reception was held at the Northfield Masonic Hall in Dr. Seeley's honor. Representatives from surrounding cities were present to pay tribute to Dr. Seeley for his years of service. A few days earlier, on August 24, Dr. and Mrs. Seeley were honored at a dinner given by Northfield physicians and the Northfield Hospital board and nursing staff.

A graduate of the University of Iowa in 1904, Dr. Seeley began his practice in Elysian. After a year there he spent two years as a physician with construction companies building the Milwaukee Railroad through the Rocky Mountains. He settled in Northfield and opened his practice there in 1908. For the past two years Dr. Stanley T. Kucera has been associated in practice with him.

* * *

Dr. J. W. Janes, Rochester, spoke on "Common Bone Malignancies" at a meeting of the Iowa State Medical Society at Carroll, Iowa, on September 7.

The Birches Sanitarium, Inc.
2391 Woodland Avenue

Attending Psychiatrists
Dr. L. R. Gowan
Dr. J. E. Haavik
Dr. C. M. Jessico
Dr. L. E. Schneider

Dr. Willis E. Lemon, Rochester, a fellow in radiology in the Mayo Foundation for the past three and one-half years, joined the x-ray department of the Chesapeake and Ohio Railroad Hospital in Clifton Forge, Virginia, on September 12. Dr. Lemon is the son of Dr. and Mrs. Willis S. Lemon of Rochester.

* * *

Dr. Ernest M. Hammes, Jr., Saint Paul, participated in the postgraduate course for general practitioners held at Charles City, Iowa, September 18, through the presentation of a paper entitled "Common Neuroses and Their Management." The course was presented under the auspices of the Iowa State Medical Society.

* * *

Dr. Gordon M. Martin, Rochester, was named fifth vice president of the American Congress of Physical Medicine at the organization's twenty-eighth annual meeting in Boston during the last week of August.

* * *

Dr. Leon L. Adcock and his wife, **Madeline S. Adcock,** have decided to dedicate themselves to the work of medical missions. They will establish a dispensary at Berekum on the Gold Coast of Africa under the direction of the Medical Mission Sisters. Until recently they served as resident physicians at St. Joseph's Hospital, Saint Paul.

* * *

Dr. H. L. Smith, Rochester, presented a paper entitled "The Movements and Sounds of Heart Valves in Various Laboratory Animals" at the International Cardiologic Congress in Paris on September 9.

* * *

The Golden Anniversary Dinner of the *American Journal of Nursing* was held on October 10, 1950, at the Waldorf-Astoria Hotel, New York.

Otto L. Wiese, editor and publisher of *McCall's Magazine,* acted as toastmaster. Serving on the Committee of Sponsors for the occasion were: Helen Hayes; Dr. Elmer L. Henderson; Senators Irving M. Ives and Herbert H. Lehman; Henry R. Luce, editor of *Time, Life* and *Fortune;* General George C. Marshall, and Mary Martin, star of South Pacific. Mrs. Eleanor Roosevelt addressed the guests on the subject, "The Nurse and the World of Tomorrow."

* * *

The Health Insurance Council, made up of the leading trade associations in the life and casualty insurance fields, has reported great gains in voluntary health insurance in 1949.

At the year's end 44 per cent of the entire population was covered by hospital insurance and nearly 60 per cent of the employed civilian population was protected against loss of income because of disability.

The total number of persons covered under voluntary accident and health insurance plans for hospital expense increased in 1949 to 66,044,000 from 60,995,000 a year earlier, a gain of 8 per cent. Those covered for surgical expense increased to 41,143,000 from 34,060,000, an increase of 21 per cent.

Coverage for medical expense increased from 12,895,000 to 16,862,000, a gain of 31 per cent.

Gentlemen:

☐ Please put my name on your mailing list to receive your municipal offerings.

☐ Please send me a copy of your chart showing comparison of Tax free vs. taxable income.

NAME ....

ADDRESS ....

CITY .... STATE ....

We invite you to write us for information concerning coupons that you will be glad to clip

We refer, of course, to the semiannual interest coupons attached to municipal bonds. Such coupons, when due, may be deposited for credit in your own bank and the income they represent is not subject to present Federal Income Taxes.

You invest savings in municipal bonds for security and income. The investment is made for a definite length of time (each bond has a maturity date) therefore day to day market fluctuations are of little concern to you.

Your primary concern is to reinvest your savings as the bonds mature and to remember to clip the right coupons.

We shall be pleased to send you information and descriptive circulars pertaining to municipal bonds that we have currently available.

Hospital. Dr. John A. Watkins, Windom, has been made secretary of the group.

Northwestern Hospital, Minneapolis.—Dr. Claude J. Ehrenberg is the new president of the medical staff of Northwestern Hospital. Other officers include Dr. Hewitt B. Hannah, vice president; Dr. Norman E. Rud, secretary-treasurer; Dr. Robert E. Priest, chief of surgery; Dr. Harold E. Miller, chief of medicine; Dr. William P. Sadler, chief of obstetrics and gynecology, and Dr. Donald H. Daniel, chief of general practice. In addition to the officers, members of the executive committee include Dr. Albert T. Hays, with Dr. Cyrus Hansen, radiologist, and Dr. Stanley V. Lofsness, pathologist.

* * *

A new thirty-five bed **convalescent hospital** was opened on September 1 at 2200 Park Avenue, Minneapolis. Manager and director of the hospital is Mr. T. W. Donohue. Dr. Archa E. Wilcox is medical advisor to the hospital.

* * *

An appropriation of $30,000 to maintain a surgical research unit at **Ancker Hospital,** Saint Paul, was approved for 1951 by the Ramsey County Welfare Board and the Saint Paul City Council. The laboratory, which will concentrate primarily on developing heart operations, will be built by private subscription and maintained by the county and city.

* * *

A campaign to raise $168,000 for the construction of a new fifty-bed **St. Francis Hospital** in Shakopee was launched early in September. Getting the campaign off to a good start, a total of $12,000 was pledged by eight physicians in the area.

It is estimated that the completed hospital, fully equipped, will cost about $675,000. The Sisters of St. Francis, who will operate the hospital, will provide $250,000, and a grant from the federal government will provide an additional $303,750.

* * *

Dr. B. W. Mandelstam, administrator of **Mount Sinai Hospital,** being completed in Minneapolis, announced on September 2 that Twin Cities physicians were invited to apply for part-time staff positions at the hospital. He also announced three full-time appointments: Dr. S. Steven Barron, pathologist; Dr. Jack Friedman, radiologist, and Dr. Irving Greenfield, anesthesiologist.

BLUE CROSS-BLUE SHIELD NEWS

More than $5,000 a day including Saturdays, Sundays and holidays is being paid to licensed and registered doctors of medicine by the Minnesota Medical Service, Inc., for services rendered to Blue Shield subscribers. An average of $5,439.65 was paid each of the 243 days between January 1 and August 31, 1950. Each of the 171 work days in the first eight months of 1950 show $7,730.03 going to doctors of medicine for services rendered Blue Shield subscribers. Doctors' services totaling 40,679 were paid during this eight-month period as compared with 21,698, an increase of 19,981 services or 49.1 per cent over the same period of 1949. Excluding Saturdays, Sundays and holidays, the number of checks made ready for mailing each day was 121.

Every effort is being made by the Blue Shield to process doctors' Medical Service Reports promptly so that the physicians will receive their checks in the shortest possible time.

For Your Information

At the end of August, there were 2,691 Blue Shield-participating doctors of medicine in Minnesota. The Blue Shield office is attempting to contact all nonparticipating doctors of medicine, however it would be appreciated if doctors who are at the present time nonparticipating would contact the Blue Shield office relative to enrolling as participating doctors. Also, if you know a colleague who does not participate why not mention it to him for the more participating physicians, the stronger the plan.

To help speed up the processing of Blue Shield cases it would be appreciated if full information could be listed on the reports when first submitted. This information would include the subscriber's group and contract number, the patient's birth date, the diagnosis, type of services rendered the subscriber and other pertinent data. Any information omitted from the report form only tends to delay the processing of that case.

The Minnesota Blue Shield office is receiving an increasing number of requests from licensed and registered doctors of medicine in Minnesota for Blue Shield contracts for themselves and their families. It is regretted that at the present time it is the ruling of the Board of Directors of the Minnesota Blue Shield that physicians cannot apply for and receive Blue Shield contracts. Briefly, the reason is that due to medical ethics physicians tend to render each other medical care on a courtesy basis and to allow licensed and registered doctors of medicine to have a Blue Shield contract would mean that they were using their own organization, Blue Shield, for reimbursement of a service that is ordinarily not reimbursed. Blue Cross, however, is available to doctors in the State of Minnesota and if any physician should desire a Blue Cross contract for himself and his family it is suggested that the request be sent to the Enrollment Department of Minnesota Blue Cross and Blue Shield.

THE PROSTATE GLAND. Herbert R. Kenyon, M.D., Associate Clinical Professor, Department of Urology, New York University, Bellevue Medical Center. 194 pages. Illus. Price $2.95, cloth. New York: Random House, 1950.

CEREBRAL PALSY. By John F. Pohl, M.D., 224 pages. Illus. Price $5.00. Saint Paul: Bruce Publishing Company, 1950.

For quite a number of years a great deal of interest has been focused on cerebral palsy, especially in children. We have witnessed the organization of many groups whose main interest lies in this condition, which claims about half a million victims in the United States. Rehabilitation centers and special schools for handicapped children have sprung up, and many other groups dealing with crippled children have shown increased interest in cerebral palsy, all of which proves the recognition of the importance of this condition and the necessity of using all possible methods for its relief. For these reasons, the appearance of this book is particularly timely and important.

The first chapter states concisely the medical problem. The pathologic anatomy, the different types of cerebral palsy are described, also the diagnostic problems and the evaluation of the mentality. The next chapter goes into the general plan of treatment—muscular relaxation, training of voluntary muscle control and building of developmental patterns. Portions of this chapter deal briefly with drugs, braces, surgical manipulations and outright surgery (brain, cord, nerves, muscles, tendons and skeleton). One chapter is devoted to the important principle of relaxation, while four chapters are needed for neuromuscular training of the various parts of the body. Here we find specific methods to help the patient in gaining voluntary control of muscles by establishing muscle-consciousness, by securing muscle function and co-ordination. The directions are described in detail for the various muscle groups, always complemented by good, instructive photographs. Chapter VIII takes up the training for developmental patterns, taking as an example the progress of such patterns in the normal infant (rolling over, creeping, et cetera) with walking as its ultimate goal (Chapter IX). The last two chapters, which are rather extensive, deal with occupational therapy and speech. The importance of the occupational therapy is very obvious, not only as a means for strengthening and increasing the control of muscles, but as these are "accomplishments for which the child can see a definite purpose, and because they are of immediate usefulness, will attract his co-operation in treatment." The variety of work exercises is remarkable, and these exercises are presented in excellent, clear form. This part includes an important portion on teaching the palsied child to eat by himself and the special eating utensils which are very helpful for the badly handicaped patient. Much space is given to teaching and correcting the speech. This part of the book is most explicit and complete in the discussion of the various defects encountered in these cases and the therapy needed to correct them. As in all the other chapters, many instructive photographs are a helpful feature.

This small volume of 224 pages (which includes an index of 11 pages) is remarkably complete and instructive. The division of the material is good, and each chapter is worked out to such an extent that it gives full information and instruction to anyone interested in this field as a whole or any part of it. The 131 illustrations increase the value of this book considerably. It should be studied most thoroughly by all workers in this field of occupational therapy and speech teachers, but it should also be of great value to physicians and medical students, especially in the branches of pediatrics, orthopedics and neurology. The palsied child owes thanks to the author for the help it will receive through better information and training of his teachers by this work.

WANTED—Woman Physician to do Obstetrics and Pediatrics, assist older well-established F.A.C.S. Excellent hospital facilities. Salary and percentage from start. Minnesota license or National Boards Parts 1 and 2. Located in suburb of Twin Cities; apartment available. Wonderful opportunity for future. Address E-225, care Minnesota Medicine.

FOR SALE—Complete modern Westinghouse x-ray equipment, basal metabolism machine, other electrical equipment, instruments, examining table, furniture, et cetera. Will sell at sacrifice for quick disposal. Retiring. Address Charles P. Robbins, M.D., S.W. Corner Third and Center Streets, Winona, Minnesota.

OPPORTUNITY—Newly remodeled physicians' suite suitable for two doctors; fourteen efficient rooms over modern pharmacy on University Avenue, Saint Paul. For information, call Mr. M. J. Collatz, United Properties, Garfield 4303.

WANTED IMMEDIATELY—Young assistant for busy young general practitioner, must have one year internship, rapidly developing industrial community in Northern Minnesota. Salary and commission. House available. Small hospital. Good schools. Address E-229, care Minnesota Medicine.

WANTED—Young man for permanent position with small clinic group; to do primarily obstetrics. Extra training in this field desirable but not essential. Address E-230, care Minnesota Medicine.

WANTED—Ophthalmologist, preferably EENT, by well-established South Minneapolis Clinic. Clinic group occupies own new building. For particulars, write E-231, care Minnesota Medicine.

Mass case finding in hospitals can be effective if applied to two groups—admissions and personnel. It is known that our medical and nursing personnel are only too often exposed to active cases of unknown tuberculosis. This is especially hazardous in the general hospital since the prophylactic nursing techniques usually fall short of those required in a communicable disease institution. The incidence of tuberculosis among doctors and nurses is already several times that of comparable age groups in the general populations, and they should not be needlessly exposed when the method of detection is so readily available.—Hospital Council of Greater New York and Tuberculosis and Health Association, 1950.

Sunshine... *every day... every month*

Mead's Oleum Percomorphum permits a happy independence of the sun as a source of vitamin D. Neither rain nor clouds nor shorter winter days interfere with the child's receiving his daily quota of vitamin D when dependable Mead's Oleum Percomorphum is administered.

Highly potent, Mead's Oleum Percomorphum is economical, too. It provides your patients with year-round protection against deficiency of vitamins A and D

Mead's Oleum Percomorphum is available in liquid form in bottles of 10 and 50 cc., accompanied by a dropper for easy dosage measurement.

Easy-to-take Mead's Oleum Percomorphum Capsules, ideal for older children and adults, are available in bottles of 50 and 250.

PARKE, DAVIS & CO.
DETROIT, MICH., U.S.A.

When prolonged estrogenic therapy is required, as in the treatment of the menopausal syndrome, increased economy is achieved with STERI-VIALS THEELIN IN OIL and STERI-VIALS THEELIN AQUEOUS SUSPENSION. Steri-Vials are rubber-diaphragm-capped 10 cc. vials from which repeated doses can be withdrawn under sterile precautions. Further advantages result from the high potency and chemical purity of THEELIN.

It effectively relieves menopausal symptoms, is well tolerated, and confers a sense of well-being associated with naturally-occurring estrogens. Its availability as oily solution or watery suspension permits flexibility in administration and individualized therapy. THEELIN IN OIL is quickly absorbed and its therapeutic action is promptly manifested. Absorption of THEELIN AQUEOUS SUSPENSION is slower and more sustained.

Financial worry

We hope that you will never have to use what we have to offer for sale. Strange, isn't it? But to view it from a different angle we certainly have no desire to see you have a misfortune such as a fire—a robbery—an accident or some sickness. Yet the law of average is moving your way. The really strange thing is that few people do what they should to eliminate worries over financial loss. Just check yourself.

This misfortune might never happen to you. But isn't it wise to put away a little money each year into a plan of Accident and Health Insurance that has been critically investigated by your Association so that you won't have to worry about financial loss?

Delay offers no advantage!

"In general, symptomatic improvement [of menopausal symptoms] was striking within 7 to 14 days after treatment..." with "Premarin."

Gray, L.: J. Clin. Endocrinol. 3:92 (Feb.) 1943.

Many clinicians have found that "Premarin" therapy usually brings about prompt relief of distressing menopausal symptoms. Furthermore, symptomatic improvement is followed by a gratifying sense of well-being in a majority of cases. This is the "plus" in "Premarin" therapy which tends to quickly restore the patient's normal mental outlook.

Four potencies of "Premarin" permit flexibility of dosage: 2.5 mg., 1.25 mg., 0.625 mg., and 0.3 mg. tablets; also in liquid form, 0.625 mg. in each 4 cc. (1 teaspoonful).

While sodium estrone sulfate is the principal estrogen in "Premarin," other equine estrogens...estradiol, equilin, equilenin, hippulin...are probably also present in varying amounts as water-soluble conjugates.

ACCEPTED COUNCIL ON PHARMACY AND CHEMISTRY AMERICAN MEDICAL ASSOCIATION

NEO-IOPAX®

(brand of sodium iodomethamate)

An 18 year history of dependable roentgenograms obtained without harm to the patient distinguishes the career of Neo-Iopax as a diagnostic urographic agent. Since 1932, *hundreds of thousands of doses of* Neo-Iopax have been injected with virtual freedom from serious untoward reactions. No other urographic contrast medium has equalled the safety record of Neo-Iopax. No agent, experience with which is limited to a relatively small number of patients, can be deemed to be as safe. Because the patient's life and welfare take precedence over all other considerations in diagnostic investigation of the urinary tract, urologists and roentgenologists will continue to rely—as always—on Neo-Iopax.

Available as a stable, crystal-clear solution of disodium N-methyl-3, 5-diiodo-chelidamate in 10, 20 and 30 cc. ampuls of 50% concentration. Neo-Iopax 75% concentration in 10 cc. ampuls, box of 5 ampuls; 20 cc. boxes of 1, 5 and 20 ampuls.

SCHERING

Nothing Competes with the Lure of Sweets

Use it in Sulfonamide Therapy

● Reactions ranging from mild antagonism to overt rebellion are to be expected when children are confronted with bad-tasting medicine. Contrast this with juvenile enthusiasm for DUOZINE *Dulcet* Tablets. Here's medicine that sweets-loving small fry (and many adults) really enjoy—sulfadiazine-sulfamerazine disguised in orange-colored, candy-flavored cubes. Mothers find DUOZINE *Dulcet* Tablets easy to administer in exactly the prescribed dosage. You'll find them effective in many systemic infections. The combined sulfonamides are independently soluble in the urine, with the result that high blood levels can be maintained with small likelihood of crystalluria and renal damage.

DUOZINE *Dulcet* Tablets, sulfadiazine-sulfamerazine in equal parts, are available in 0.3-Gm. and 0.15-Gm. potencies, bottles of 100. Mighty "take-able" medication when sulfonamides are indicated. Abbott

A Real American Breakfast

That a nutritious breakfast providing generous amounts of high quality protein prevents late morning hypoglycemia has been amply demonstrated. As shown by Thorn and co-workers,[1] and later confirmed by Orent-Keiles,[2] ". . . breakfast high in protein and low in fat and carbohydrate was followed by an improved sense of well-being and no symptoms of hypoglycemia."

Meat for breakfast—ham, sausage, bacon, breakfast steaks—is an appetizing means of increasing the protein content of the morning meal. Its biologically complete protein contains all essential amino acids, and serves well in complementing less complete proteins from other sources. Furthermore, muscle meat is an outstanding source of B complex vitamins and of iron.

The Seal of Acceptance denotes that the nutritional statements made in this advertisement are acceptable to the Council on Foods and Nutrition of the American Medical Association.

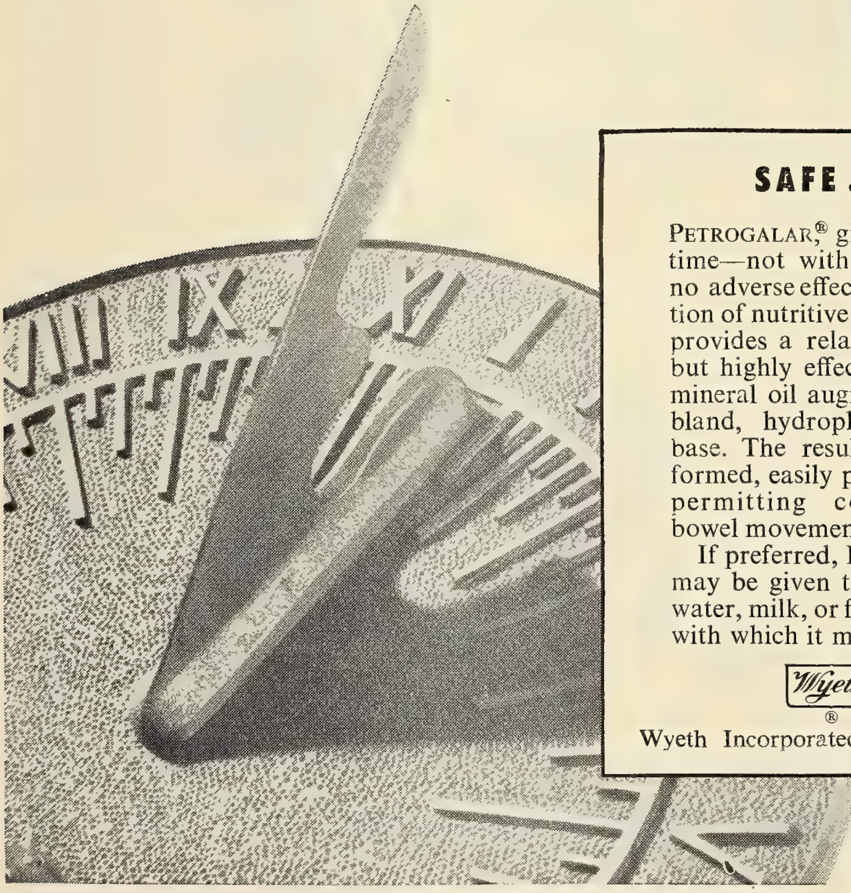
HABIT TIME OF BOWEL MOVEMENT

ONE PINT
PKG 1896
Wyeth
Petrogalar
Aqueous Suspension of Mineral Oil Plain
Active Ingredient: Mineral Oil 65%
DIRECTIONS: Adults, one tablespoonful. Children over six years old, one teaspoonful. May be thinned with water, milk or fruit juice if desired.
CAUTION: To be taken only at bedtime. Do not use at any other time or administer to infants, except upon the advice of a physician.
SHAKE WELL
Wyeth Incorporated



SAFE . . .

PETROGALAR,® given at bedtime—not with meals—has no adverse effect on absorption of nutritive elements. It provides a relatively small but highly effective dose of mineral oil augmented by a bland, hydrophilic colloid base. The result is a soft-formed, easily passed stool, permitting comfortable bowel movement.

If preferred, PETROGALAR may be given thinned with water, milk, or fruit juices—with which it mixes readily.

Wyeth®

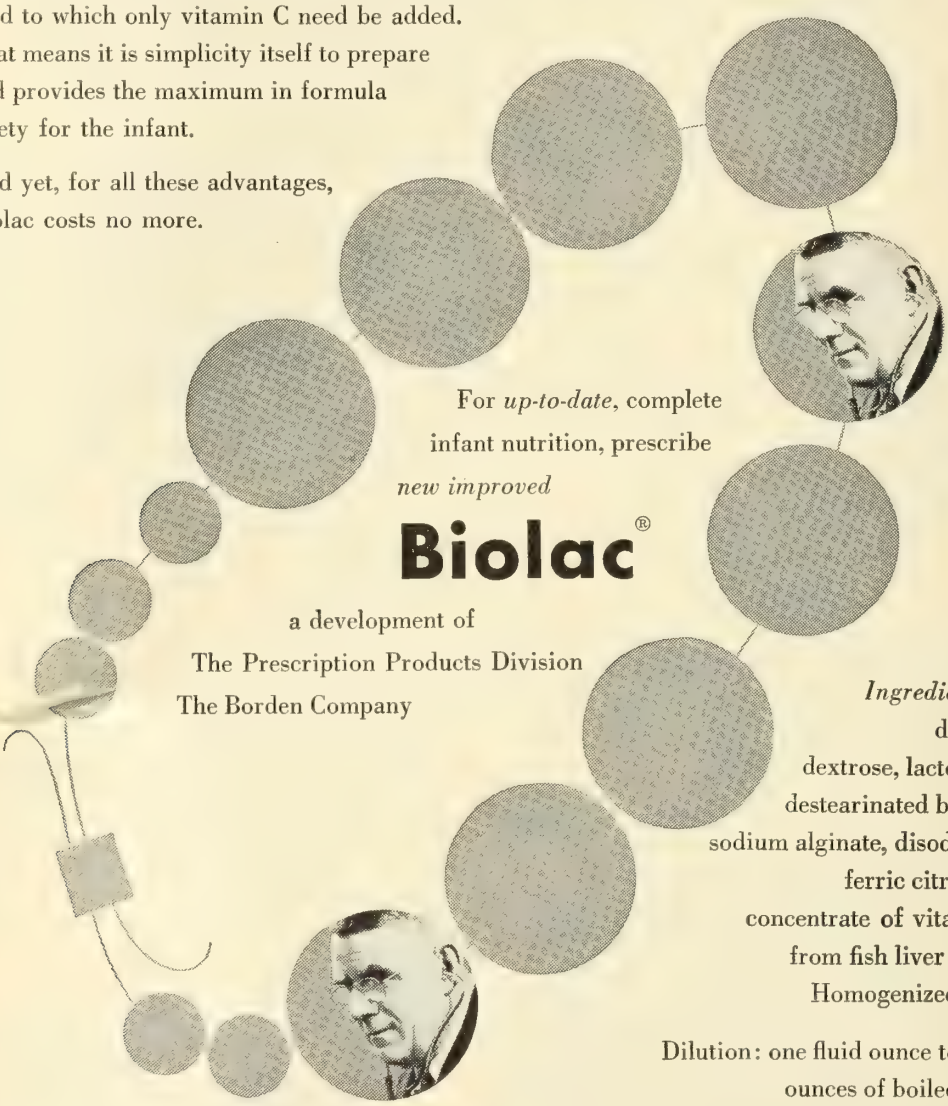
Wyeth Incorporated, Phila. 3, Pa.

more physicians are satisfied

The development of the new improved Biolac supplies a long-sought need in infant nutrition. To accomplish this, Borden scientists surveyed our present nutritional knowledge. They then tested more than 500 formulations. Having decided on the formula that would best supply the normal infant's nutritional requirements in their most assimilable form, a modern plant was constructed in 1949 so that the new formula could also benefit from the most up-to-date techniques and control in processing equipment. A Biolac formula that is both new and improved is thus made available.

Biolac is intended for prescription by every physician with infants among his patients. It satisfies the physician's demand for a complete food to which only vitamin C need be added. That means it is simplicity itself to prepare and provides the maximum in formula safety for the infant.

And yet, for all these advantages, Biolac costs no more.



For *up-to-date*, complete infant nutrition, prescribe *new improved*

Biolac®

a development of
The Prescription Products Division
The Borden Company

Ingredients: skim milk, dextrins-maltose-dextrose, lactose, coconut oil, destearinated beef fat, lecithin, sodium alginate, disodium phosphate, ferric citrate, vitamin B_1, concentrate of vitamins A and D from fish liver oils, and water. Homogenized and sterilized.

Dilution: one fluid ounce to one and a half ounces of boiled water for each pound of body weight.

Biolac is available in 13 fluid ounce tins.

AUREOMYCIN

CRYSTALLINE

in Primary Atypical Pneumonia

The chemotherapy of primary atypical pneumonia has until recently been unsatisfactory. Aureomycin, which favorably influences the course even of severe cases, is now accepted as a treatment of choice in this disease.

Aureo-
mycin

Capsules: Bottles of 25, 50 mg. each capsule. Bottles of 16, 250 mg. each capsule.

Ophthalmic: Vials of 25 mg. with dropper; solution prepared by adding 5 cc. of distilled water.

Aureomycin has also been found effective for the control of the following infections: acute amebiasis, bacterial and virus-like infections of the eye, bacteroides septicemia, boutonneuse fever, acute brucellosis, common infections of the uterus and adnexa, resistant gonorrhea, Gram-positive infections (including those caused by streptococci, staphylococci, and pneumococci), Gram-negative infections (including those caused by the coli-aerogenes group), granuloma inguinale, *H. influenzae* infections, lymphogranuloma venereum, psittacosis (parrot fever), Q fever, rickettsialpox, Rocky Mountain spotted fever, subacute bacterial endocarditis resistant to penicillin, surgical infections, tick-bite fever (African), tularemia and typhus.

Pure Crystalline
Vitamin B_{12}

The Only Form
Of This Important
Vitamin
Official In The U. S. P.

PREFERRED BECAUSE
potency, purity, and lack of toxicity of *crystalline* vitamin B_{12} are clearly established.

Potency: Potency of this U.S.P. product is accurately determined by precise weight.

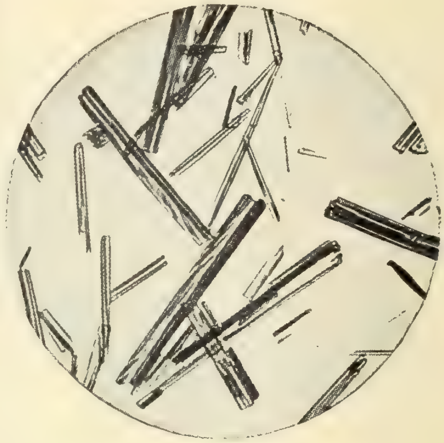
Purity: Pure anti-anemia factor.

Efficacy: Produces, in microgram dosage, maximum hematologic and neurologic effects.

Tolerance: Extremely well tolerated; "no evidence of sensitivity" has been reported.

Toxicity Studies:
In recent pharmacologic investigations, extremely large doses of *crystalline* vitamin B_{12} (1,600 mg./Kg.) caused no toxic reactions in any of the animals treated. In contrast, 3 mg./Kg. of a "*concentrate*" caused fatal reactions in 100 per cent of the animals treated.

Merck—first to isolate and produce vitamin B_{12}—supplies Crystalline Vitamin B_{12} in saline solution under the trademark Cobione.* Your pharmacist stocks Cobione in 1 cc. ampuls containing 15 micrograms of crystalline vitamin B_{12}.



Crystalline Vitamin B_{12}

* *Cobione is the registered trade-mark of Merck & Co., Inc. for its brand of Crystalline Vitamin B_{12}.*

THE RADIOACTIVE EFFECTS OF ATOMIC WEAPONS

ASHER A. WHITE, M.D.

Minneapolis, Minnesota

IN discussing the physiologic effects of radiation, consideration must be given to the manner in which radioactivity is encountered. Man has for many years had intimate and reasonably accurate knowledge of the radioactivity emanating from x-ray machines and from radium. More recently work with cyclotrons has given rise to radioactive forms of many of the common elements. During the late war, in connection with the operation of the plutonium producing piles at Richland, Washington, and Oak Ridge, Tennessee, immense amounts of radioactivity were encountered which required enormous work in planning and building for protection of personnel against such radioactivity. It was not, however, until the explosion of the first atomic bomb in July, 1945, with the subsequent explosions over Japan in August of 1945, that radioactivity became important in civil defense planning.

In present planning various factors must be given consideration. Several atomic bombs have been exploded in the air and one bomb has been exploded under water. The effects of the air or water bursts are entirely different, both practically and in relation to human contact with radioactivity. Atomic bomb explosions in air are a very poor and ineffective way of utilizing radioactivity for destruction. A much more effective way of such utilization was found at Bikini in the underwater explosion. In this instance the intense heat of the bomb explosion, totaling several million degrees centigrade, turned many thousand tons of sea water into steam, in which the enormous radioactivity of the fission products was trapped and rained back to earth as the radioactive steam condensed. These radioactive fission products fell out over an area roughly five miles in diameter and so contaminated the target ships that all had ultimately to be sunk. The presence of radioactive sludge at the bottom of Bikini Lagoon continues to make that lagoon uninhabitable for humans. The A.E.C. has reported that almost all biological organisms living in the lagoon are radioactive. It is considered, however, by civil defense planners that such water explosions are an inefficient use of the energies available in time of war, and that we need not therefore be concerned with this particular type of explosion.

The term, "radiological warfare" is one which has occasionally been used and one for which some definition should be supplied. It refers to the concept that radioactive substances might be used to contaminate the air, the water, the food or the ground upon which people live. Water soluble substances might be put into municipal water systems, radioactive substances might be sprayed by planes over selected areas of land, and other means could be used to disseminate such radioactive substances. Here again the phenomenologist concedes that such use of radioactivity will be inefficient in terms of destruction, and therefore advises that radioactivity encountered through this means will be unlikely. We will therefore confine ourselves in this discussion to the effects of an atomic bomb exploded in the air above a given area.

Presented at the short course on Civil Defense, Minneapolis, Minnesota, August 31, 1950.

The explosion of the bomb in the air above a target gives rise to four successive waves of destructive activity. The first wave travels with the speed of light and includes the components of the electromagnetic spectrum such as light, heat, x-rays and gamma rays. The second wave travels somewhat more slowly and contains myriads of atomic particles and fission products, including neutrons. Third comes the shock wave, which travels with the speed of sound, and fourth the blast wave following immediately after the shock wave. At Hiroshima and Nagasaki the dangerously radioactive fission products rose into the stratosphere harmlessly. Biological damage came from the heat, the ultraviolet energies, the gamma rays and neutrons which were liberated at the instant of explosion but which instantly dissipate and are lost. Relatively very little radioactivity is left upon the ground after such an explosion. The injuries produced by the heat, light and gamma rays are produced at the instant of dissemination and before the blast effect can strike.

One must also consider the areas over which biological effects can be produced. From the point immediately underneath the bomb or target center to one thousand yards in all directions is the zone in which almost all biological organisms will die of radioactive burns. The only animals remaining alive in this zone would be those who had been screened by some effective radiological screening substance such as concrete. In the zone next furthest out, from one thousand yards to 1,250 yards, the survivors of the Japanese blasts were relatively few and those who did survive showed maximum radiological effects. The third zone, from 1,250 to 1,500 meters, gave rise to far fewer deaths, but in most persons in this area the radiological burns were severe. In the area from 1,500 to 1,750 yards from target center, severe superficial burns were produced, but no immediate radiological effects were noticed, although many individuals suffered delayed effects. In the zone 1,750 yards to 2,000 yards, even these delayed effects were few, although many superficial burns were encountered.

In this connection the experience of the Japanese in Hiroshima and Nagasaki are our best examples. In the Japanese, the injuries produced were a composite of flash burns from heat and radiation burns. In addition to these effects many survivors experienced blast injuries. The manner of injuries can be well understood if one imagines that the place of bomb explosion a few hundred feet above the ground produces in effect a small sun. At that height the heat from this sun will be sufficient to burn severely those who are close enough to the center. In addition to the heat the ultraviolet light will produce a severe burn, and finally the rays of shorter wavelength such as x-rays and gamma rays will reach the body, penetrate directly through it, and cause injuries to most of the cells through which they pass. The individual thus receives his total injury all in a flash and may die immediately from the combined effects. If further away from target zero, he may die more slowly within the first day or two, or if the injury was mild enough, may survive to show the effects of internal damage of one kind or another as permanent late results. If the exposure were very light, the damage may heal with no sequelae whatever. It is not our purpose to consider the burn and blast effect, since these are older subjects and are more thoroughly understood.

TABLE I. RADIATION SENSITIVITY OF TISSUE IN DECREASING ORDER

a. Lymphocytes
b. Erythroblasts
c. Germinal epithelium of testis
d. Myeloblasts
e. Epithelium of intestinal crypts
f. Germinal cells of ovary
g. Basal layer of the skin

i. Bone
j. Liver
k. Pancreas
l. Kidney
m. Nerve
n. Brain
o. Muscle

At the instant of explosion, gamma rays and neutrons are produced, which travel with infinite speed to the target which it is intended they destroy, and penetrate these targets as deeply as the energies which they carry allow. As the gamma rays and neutrons fly through the body they produce their damage by disrupting the various tiny atoms of which body cells are composed. In the course of passage of one neutron through the body, probably many thousands of atoms are disrupted. The amount of total body damage produced depends upon the total number of neutrons and gamma rays which penetrate the body and the degree of sensitiveness of the body. The degree of sensitiveness in turn varies with the species of animal, varies between different individuals of the same animal species, and varies greatly from one tissue to another. The most sensitive tissues in the animal organism are always those tissues which are in most active growth

TABLE II. RADIATION SENSITIVITY OF MAN AND ANIMALS. NUMBER OF ROENTGENS (r) REQUIRED TO KILL 50 PER CENT OF SUBJECTS

Fruit fly eggs	150 r
Guinea pig	200 r

Mice	530 r
Rats	600 r
Rabbits	800 r
Bacteria	1,000-100,000 r

such as bone marrow, blood cells, sexual tissues and other tissues in decreasing order.

The dose of radioactivity received by any given individual varies as we have described with the distance from the blast and with the thickness of screening material between such individual and the blast.

Acute radiation sickness may take several forms, according to the severity of the exposure. The survivors in zone two will usually exhibit the fulminating form of the disease, which is characterized by the onset of nausea, vomiting, prostration and mild diarrhea within two to six hours after exposure and soon afterward of intractable diarrhea with delirium, tremors and finally death. In the early Japanese deaths there was very little evidence of external effect. Death occurred from the fifth to the tenth day. This fulminating type occurs in individuals who have received very large amounts of radiation. The hemorrhagic form of the disease occurs in those individuals who have been less hard hit with radiation. Vomiting, prostration and diarrhea occur early, lasting one or two days, and then there may be a period during which the individual seems well, lasting about five days, but this is followed by profound prostration, bloody diarrhea, and increasing fever. Bleeding into the skin and into the body orifices or cavities takes place and ulcers of mucuous membrane become more and more expansive. If the patient dies, it is usually in from three to six weeks after the exposure.

The third form of the disease is known as the pancytopenic, and is composed largely of patients in the hemorrhagic group who survive the six weeks period but continue to exhibit weakness, pallor and ulceration. Blood counts on these people show a severe diminution in all the formed blood elements. In those patients who are doomed to die from this form of the disease, loss of weight becomes more and more pronounced.

A most interesting phenomenon in connection with radiation sickness is the loss of hair from the scalp. It occurs equally in both sexes and appears about two weeks after the exposure. New hair of the same texture and color as the original hair grew in all individuals who survived.

Complications.—Acute radiation sickness in the Japanese was usually accompanied by severe blast and burn injuries, many persons dying from these injuries before the evidence of radiation sickness developed. Because of the skin and intestinal ulcers produced, bacterial infections were common, including bacterial invasion of the blood stream, pneumonia, lung abscesses and tuberculosis.

Sequelae.—Various late complications of acute radiation sickness seem possible, but as yet no extensive clinical experience with these has been obtainable in man. An extensive program of study of the Japanese survivors has been instituted in order to follow up these possibilities. If the human reacts like the experimental animal, genetic changes will be observed in the offspring of the Japanese victims but may not be observable for two, three, or more generations. Various experimental evidence indicates that malignant growths may be made to occur by heavy body radiation. A late development which has recently been found to occur in the Japanese victims is cataracts of the eyes.

Treatment.—No specific and curative treatment has yet appeared. Treatment in general depends upon rendering every possible form of support. One then hopes that the dose of radiation which the patient has received will not be sufficient to overwhelm his body defenses. Frequent transfusions of fresh blood are perhaps the most useful agent of support. Close attention to the salt and water balance will be instituted by the physician attending such a patient. Bacterial invasion may be combatted by the use of the newer antibiotic agents. Rest is important for several weeks for those patients receiving large doses of radiation. The Atomic Energy Commission announces that it is spending about one million dollars a year in studying the acute radiation syndrome. It is hoped that this study will yield some additional and more effective means of dealing with

HEALTH—AN INTERNATIONAL AS WELL AS LOCAL PROBLEM

F. W. BEHMLER, M.D.
Morris, Minnesota

PROBABLY all of us here tonight have worked with microscopes. Whether we are physicians, dentists, veterinarians, nurses, bacteriologists, engineers, or health educators, we have all studied biology. The study of life, if it is to amount to anything more than theory, requires the use of the microscope. Most of us became acquainted with this useful instrument in our high school days, and some of us have continued to use it in our work ever since. Every public health person realizes how potent the microscope has been in our fight on disease. Without it, we would not possess a fraction of our present knowledge of tuberculosis, syphilis, typhoid fever, and all the other bacterial diseases. By long and careful study, we have been able to learn many of the secrets of the minute forms of life that cause disease.

All of us, too, have had the experience of finding our eyes grow tired with long concentration on some such tiny particle as a pathogenic organism or a blood cell. In our school days we sought relief by looking away from the microscope and out of the window—over the tree tops—up at the far-away sky. But how many of us, I wonder, have gone beyond that? How many of us have ever studied the worlds beyond our own, as revealed by a giant telescope?

It may seem to you that looking at the universe through a telescope has little meaning for the public health worker. Yet at all times, and particularly at a time like the present, we may need to give our eyes and our minds a rest from the close study of immediate problems. We need to take note of what is happening in the broader world that lies beyond the scale of our microscopes.

Tonight marks the close of the fourth year of the Minnesota Public Health Conference. At each previous annual meeting, your president and other speakers have stressed the need for developing *local health services*. I know that in earlier sessions of this present conference, you have all discussed that matter and many problems related to it. We doctors, for instance, talked about the duties of the health officer in a small town. In a manner of speaking, we looked at our health problems through a microscope. Then Mr. Stowman* took us up on a hilltop and gave us a view of public health as it looks from the standpoint of the World Health Organization. He made us realize that you can't always pin down health and disease under an oil-immersion lens. You also need to look at it through the great, world-sweeping eye of a telescope.

Meeting local health needs is important—vitally important. But we must beware of developing the complacent attitude that, if we take care of our home-town problems, we need do nothing more. Our old Minnesota friend, Dr. Herman Hilleboe, has reminded us that "There can be no isolationism in the field of health. The fight against disease is not a national or racial problem; it is a task for the whole of humanity." And at the 1946 meeting of the American Public Health Association, just after the close of that war that we fondly hoped was the last one for our generation, Dr. Thomas Parran told us that "by force of events we have become citizens of the world."

Our world citizenship in matters of health has become even more apparent during the last few years. Within the lifetime of most of us, our world has shrunk to such a degree that we scarcely need a telescope to see into its remotest corners. Time and again we are reminded that disease is no respecter of international boundaries—that health problems in any part of the world are our problems.

In the United States, particularly in our own Middle West, we enjoy long life, and our general death rate is low. Our children's expectation of life at birth today is close to seventy years. Diseases that attacked us frequently in the early days —smallpox, typhoid fever, cholera—are now almost unknown in Minnesota and our neighboring states. Yet only the thinnest film of protection lies between us and many potential epidemics. As Dr. Frank Boudreau puts it, "A yellow fever mosquito may easily travel to this country as a stowaway on a plane from South America. A rat infected with plague may find its way from China,

---

Retiring president's address presented at the annual meeting of the Minnesota Public Health Conference, September 26, 1950.

*Kund Stowman, Chief, Research and Technical Advisory Branch, National Health Division, U. S. Public Health Service.

India, or South America. An apparently healthy passenger may be a carrier of cholera or other intestinal disease." And no longer can we depend upon quarantine to safeguard us. That system worked pretty well when travel was slow and the plague spots of the world were far away. In 1950, the European refugee infected with typhus, the Brazilian with malaria, the Korean with cholera, are right outside our doors. We must combat these diseases at their source in order to prevent their spread into our own vulnerable territory.

Some people live in daily fear of bacteriological warfare. If they only realized it, a sporadic, undirected bacteriological warfare is being waged against us all the time. Bacteria menace us far more widely and more constantly than bombs. Our only defense against such warfare is *the building up of international co-operation.* In a world in which co-operation on the political level seems at present an unrealizable dream, it is heartening to recall that it has existed for a long time in the field of health. Widespread public health is both an instrument and a condition of any lasting peace. In that same 1946 address by Dr. Parran from which I quoted earlier, there is also this assertion: "The World Health Organization brought together for the first time after the war, representatives of virtually all nations, including certain ex-enemy nations. It is worth while recalling that after the first World War, a conference on health was the first to bring together representatives of nations which a few months before had been at each other's throats."

And note this comment by Raymond B. Fosdick, former president of the Rockefeller Foundation:

"An American soldier wounded on a battlefield in the Far East owes his life to the Japanese scientist, Kitasato, who isolated the bacillus of tetanus. A Russian soldier saved by a blood transfusion is indebted to Landsteiner, an Austrian. A German soldier is shielded from typhoid fever with the help of a Russian, Metchnikoff. A Dutch marine in the East Indies is protected from malaria because of the experiments of an Italian, Grassi; while a British aviator in North Africa escapes death from surgical infection because a Frenchman, Pasteur, and a German, Koch, elaborated a new technique. . . Our children are guarded against diphtheria by what a Japanese and a German did; they are protected from smallpox by an Englishman's work; they are saved from rabies because of a Frenchman; they are cured of pellagra through the researches of an Austrian. From birth to death they are surrounded by an invisible host—the spirits of men who never thought in terms of flags or boundary lines and who never served a lesser loyalty than the welfare of mankind."

Well, there you have two admirable examples of the telescopic view of public health. You may agree with that view in principle. But you may say that it doesn't exactly solve your local medical, nursing, or sanitation problems, and it doesn't throw much light on what we ought to do in the present situation, when those needs are being ominously underscored by the threat of total war. Whether or not that threat materializes, it is likely that many public health people will be called upon for special services, thus jeopardizing our local health programs. I should be doing you no service if I brought my year as your president to a close with nothing more than the request that you try from now on to take a broader view of all health problems. So, let me try to round out this valediction with a few concrete suggestions.

First, we must realize that the requisites for individual, public, and world health *are all interdependent.* One individual's sinusitis or migraine may cause him to make a rash judgment, a wrong decision, a costly mistake. I should not be surprised if a future autopsy on Stalin were to reveal evidence of a gnawing gastric ulcer. Nor is it beyond the bounds of belief that nations were plunged into war a decade ago chiefly because a surly little boy named Adolf Schickelgruber was kicked around by a frustrated father and nagged by a neurotic mother. I am not suggesting that any one of us here this evening could precipitate a global war by neglecting a decayed tooth or an ingrowing toenail, but it is by no means impossible that such a thing could lead, through a series of chain reactions, to far-reaching and fatal consequences, not only for the individual concerned but also for many other persons.

Viruses are not the only things that spread without being noticed. The same process takes place with states of mind. We can infect other people from our own despondency or hostility, just as easily as from a cold in the head. Hence our first responsibility is to ourselves—to gain and maintain that condition of "complete physical, mental, and social well-being" that constitutes the World Health Organization's definition of health.

Second, in taking the long view we must not overlook our local needs. In learning to use the telescope we must never entirely substitute it for the microscope. Our goal, to be sure, is optimal health for every human being. But in order to attain that goal we must secure the active participation of as many people as possible. As Dr. Brock Chisholm points out, "Health cannot be given as a gift. It must be obtained through constant vigilance and increasing action." To maintain that vigilance, to guarantee that action, we must have broad participation in all worthwhile health measures. I have said little tonight about that phase of our responsibilities, because anything I might say is already well known to most of you. Talking about local health organization in Minnesota is like talking about the eradication of tuberculosis. We know all the facts necessary to do the job. All that remains for us now is to do it. So, may I urge upon all of you once again to take stock of your local health services and needs, and to talk about your problems with your own community leaders. Effective action in this respect will stem only from many groups of well-informed people who have a clear idea of what they need and are determined to get it and make it work. That's how local health services have come into being in other states. Ask them how they did it, and the answer always boils down to the simple statement that a lot of people wanted it. When enough people want something, they eventually get it.

No matter what the immediate future may hold, public health services in our state should not be curtailed. Whatever defensive measures may be set up against possible attack, those measures will be centered in and directed by our public health organization. In that task, as in many others, this Minnesota Public Health Conference is now in a position to give strong leadership. It is true that we are a young organization. But in times of crisis, young people often have to grow up pretty fast. The fact that we have already gained recognition by the American Public Health Association speaks well for our progress toward maturity. That progress will be aided, and our ability to carry responsibility will be increased, by the addition to our membership of more members of the health professions and more lay people who have an intelligent and active interest in community health.

We see before us today, as we have seen in previous years, the spectacle of many nations that have fallen under the heel of dictators because they did not know or did not care enough to hold on to their liberties. We will not join them unless we allow our democratic processes to lapse. One way of maintaining those democratic processes is to build up associations in which, as in this conference of ours, we work for the benefit of everyone through the active participation of all qualified people.

We have talked tonight about science—about using the instruments of science for the discovery of truth and the promotion of health. Our generation has learned through hard experience the tragic *neutrality* of science. It may be used to save life or to destroy it. But we have not abandoned science for that reason. Nor do we have any intention of doing so. Through the gradual spread of knowledge, we may hope to bring about the end that we so greatly desire—the attainment of universal peace and security. Improvement of the physical, mental, and social health of all nations is essential to that end. We need to establish in every country a nucleus of workers who have the necessary training and skill to promote all aspects of health.

This is not a one-sided missionary endeavor for the American people. Let us never make the mistake of assuming that all knowledge and all truth are in our possession. There is much that we can learn from other countries, even as they have much to learn from us. We need to pool *all* health knowledge—to work with all people of good will everywhere toward the achievement of worldwide health. To do this effectively we must continue to use both the microscope and the telescope —to study intensively our own health needs and those of our home communities, our state, and our nation, but at the same time to look beyond these immediate concerns to those of all the nations of the earth.

FLATFOOT, WITH SPECIAL CONSIDERATION OF TARSAL COALITION

MARK B. COVENTRY, M.D.
Rochester, Minnesota

FLATFOOT is one of the common causes of foot pain.[2] Certain types of flatfoot are more disabling than others. Flatfoot causes more discomfort in adolescence than in later life. The patient tends to modify his life to his disability as he gets into the twenties and thirties. Canadian Army statistics, based on examination of 3,600 young men, disclosed that 8 per cent of the men had some form of disabling flatfoot.

A new concept regarding the cause of rigid flatfoot recently has been advanced by Harris and Beath.[5] This has changed the thinking about this particular type of flatfoot. It is, therefore, felt that a review of flatfoot, particularly rigid flatfoot, will be timely.

Classification of Flatfoot

Flatfoot may be divided into three main types, which are listed in Table I.

TABLE I. CLASSIFICATION OF FLATFOOT

I. Flattened longitudinal arch. This is a structural and asymptomatic derangement; it is not a pathologic condition.
II. Relaxed flatfoot. Hypermobile flatfoot with short tendo achillis.
III. Rigid flatfoot.
    A. Coalition of the tarsus.
        1. Classification as to type of union.
            a. Fibrous.
            b. Cartilaginous.
            c. Bony.
        2. Classification as to site.
            a. Talocalcaneal.
            b. Calcaneonavicular.
            c. Involvement of other tarsal bones.
    B. Arthritis of tarsal joints.

Flattened Longitudinal Arch

The most common type of flatfoot is a simple flattening of the longitudinal arch. This type of flatfoot is not painful. It is an individual characteristic, like the shape of the head or the length of the arms, and is familial. Ankle valgus is not present, and there is no rigidity or hypermobility. This type of flatfoot is not affected by weight bearing, and it does not produce any roentgenographic changes except a depression of the longitudinal arch.

It is extremely important to recognize this entity for what it is—a symptomless, nonpathologic, individual characteristic. If the patient has foot pain, one must search elsewhere for its cause.

Relaxed Flatfoot

Relaxed flatfoot also has been designated by the term "hypermobile flatfoot with short tendo achillis," which is lengthy but descriptive. This type of flatfoot is pathologic and is a well-known clinical entity. Examination disclosed that approximately 6 per cent of 3,619 recruits for the Canadian Army had mild or severe flatfoot of this type.[4,5] The deformity exists from childhood, but pain does not occur until adolescence.

Three basic theories have been advanced to explain the cause of relaxed flatfoot: (1) congenital relaxation of the supporting tarsal ligaments; (2) congenital shortening of the triceps surae group of muscles resulting in shortening of the tendo achillis, which pulls on the calcaneus and causes a valgus position of this bone, and (3) congenital deficiency in the skeletal support of the talus.

Harris and Beath[4] expressed the opinion that the basic cause of this type of flatfoot is improper support of the talus by the anterosuperior portion of the calcaneus. This results in a dropping downward and inward of the talus, which, of course, flattens the longitudinal arch and produces a prominence of the head of the talus on the medial side of the foot, and valgus of the ankle. Shortening of the tendo achillis occurs secondarily. Pain is caused by excessive ligamentous strain, and traumatic arthritis frequently develops in later years.

The characteristics of the relaxed flatfoot with a short tendo achillis are ankle valgus, flattening of the longitudinal arch, and a medial prominence of the foot (Fig. 1*a* and *b*). The normal contour of the longitudinal arch is restored when the weight of the body is removed from the feet (Fig. 1*c*). A shortened tendo achillis is shown in Fig. 1*d*. Dorsiflexion beyond 90 degrees is not possible. When testing the extent of dorsiflexion, the patient's knee should be in a neutral position, not in a flexed or hyperextended position. A further characteristic, emphasized by Harris and Beath,[4] is hypermobility of the midtarsal joints which can

---

Read at the meeting of the Minnesota State Medical Society, Duluth, Minnesota, June 12 to 14, 1950.

From the Section on Orthopedic Surgery, Mayo Clinic, Rochester, Minnesota.

be elicited by holding the calcaneus in the palm of the left hand and moving the fore part of the foot medially and laterally.

Roentgenographic examination is helpful, although not diagnostic. The talus is seen to be placed medially and inferiorly on the calcaneus. A lateral deviation of the fore part of the foot on the talus also occurs (Fig. 1*e* and *f*). One should read the Army Foot Survey by Harris and Beath[3] for accurate measurements of the tarsal bones and for a description of relaxed flatfoot.

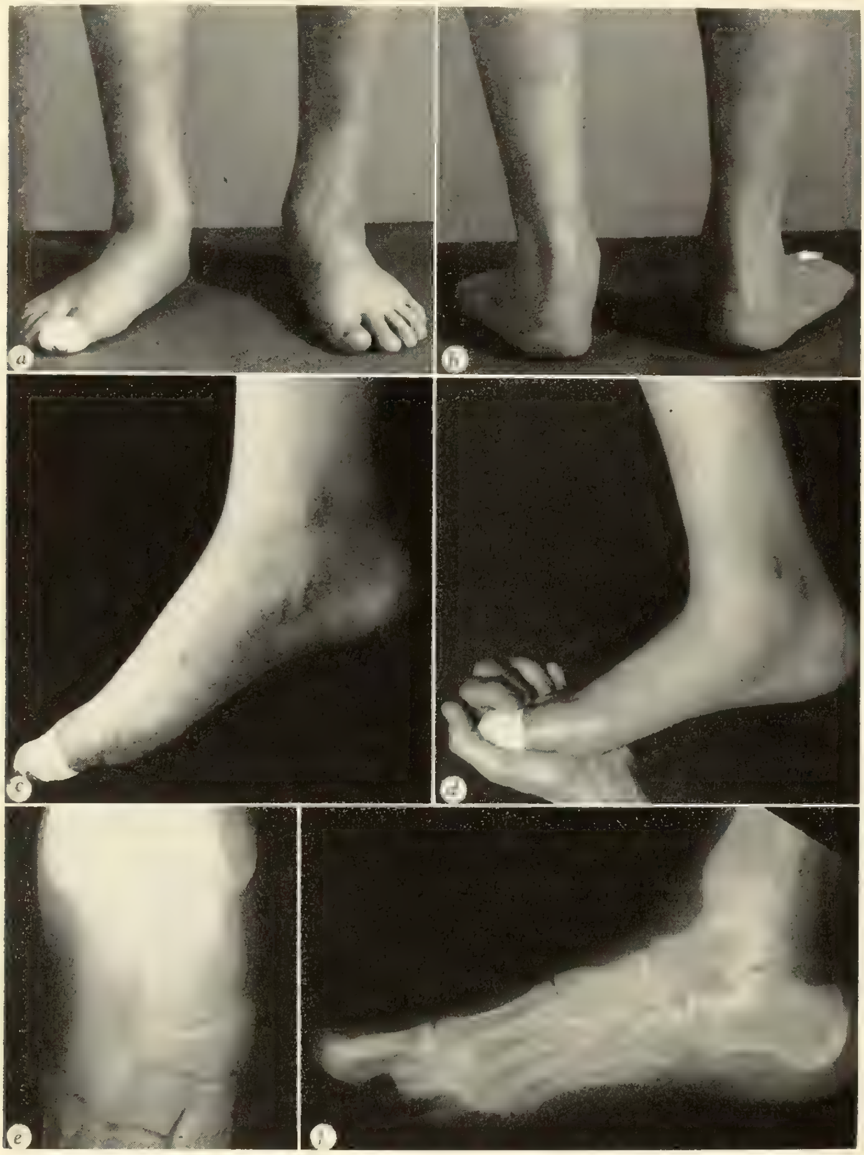

Fig. 1. Hypermobile flatfoot with short tendo achillis. *a*, Front view; *b*, rear view; *c*, appearance of arch without weight bearing; *d*, maximal dorsiflexion obtainable; *e*, anteroposterior roentgenogram; *f*, lateral roentgenogram.

Treatment of relaxed flatfoot is directed toward support of the talus. Active support is laudable but seldom possible. In cases in which the deformity is not severe, exercises to strengthen the supporting muscles of the foot are sometimes of value if the patients are co-operative. A passive form of support usually is necessary, however. In these cases longitudinal arch supports of metal, cork, sponge rubber, felt, leather or other material usually will relieve the symptoms. In addition, a wedge may be placed on the inner part of the heel of the shoe if there is much ankle valgus. In cases in which relaxed flatfoot causes considerable disability and is not relieved by this form of treatment, operation often is necessary. Many operations have been devised for relief of pain in the relaxed flatfoot. Lengthening of the tendo achillis alone has been advocated by some surgeons. Stabilization of the talonavicular, naviculocuneiform and cuneiform-metatarsal joints alone or in combination has been advocated. Plication of the medial tarsal ligaments combined with tendon transplantation with or without arthrodesis, also has been used. However, if operation is indicated, triple arthrodesis, that is, calcaneotalar, calcaneocuboidal and talonavicular arthrodesis, probably is the procedure of choice. Operation should be done, as a rule, when patients are in the teens or early twenties. As mentioned previously, the patients usually adjust to a sedentary life after they reach the twenties, and operation is seldom indicated then.

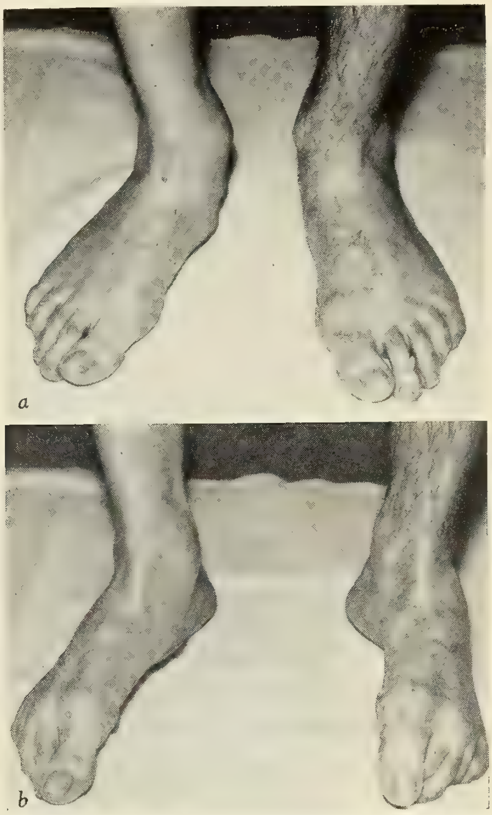

Fig. 3. Calcaneonavicular coalition (Case 4). *a,* Appearance of feet; bony coalition on right side (shaved); fibrous coalition on left side (unshaven); *b,* limitation of inversion.

Rigid Flatfoot

Except in a very few cases of tarsal arthritis resulting from rheumatoid arthritis, infection or trauma, rigid flatfoot is due to tarsal coalition. Coalition, by definition, means the growing together, or union of. Applied specificially in this case, it denotes the union of two or more tarsal bones. The union may be fibrous, cartilaginous or bony (Table I), and it may occur between the calcaneus and the talus, between the calcaneus and the navicular (Fig. 2*a, b,* and *c*), or rarely between other tarsal bones.

Rigid flatfoot has been most commonly called "peroneal spastic flatfoot" in the past. Owing chiefly to the writings of Harris and Beath,[5] this concept is being discarded. The rigidity of this

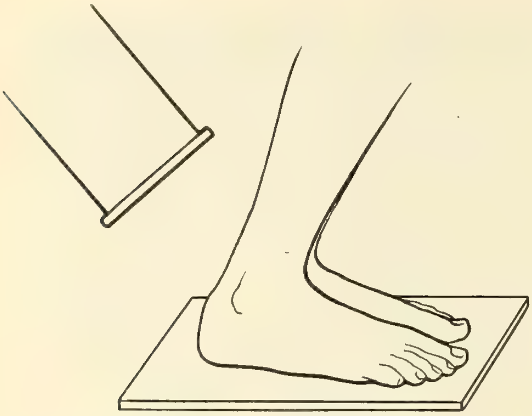

Fig. 4. Positioning for making special roentgenograms ("coalition views") to demonstrate calcaneotalar coalition.

type of flatfoot is caused by actual union of the tarsal joints, and not by spastic peroneal muscles. The peroneal muscles are not spastic, but simply tight because the tarsal rigidity prevents their stretching in a normal fashion. Inversion of the foot is impossible in cases of rigid flatfoot. Harris and Beath said that anatomists have known of tarsal coalition for fifty years. Sporadic reports of cases of calcaneonavicular coalition appeared in the literature in 1921,[7] 1923[6] and 1927,[1] but the entity calcaneotalar coalition was not described clinically until Harris and Beath[5] published their significant report in 1948.

The incidence of tarsal coalition was 2 per cent among 3,600 men who were examined for enlistment in the Canadian Army.[5] Operation disclosed tarsal coalition in five cases which were observed at the Mayo Clinic in 1948 and 1949. In three of these cases, the coalition involved the calcaneus and talus; in the remaining two cases, it involved the calcaneus and navicular. The anomaly undoubtedly was present but was not recognized in other cases which were observed in the same period. We are recognizing more and more cases as our knowledge of the subject increases.

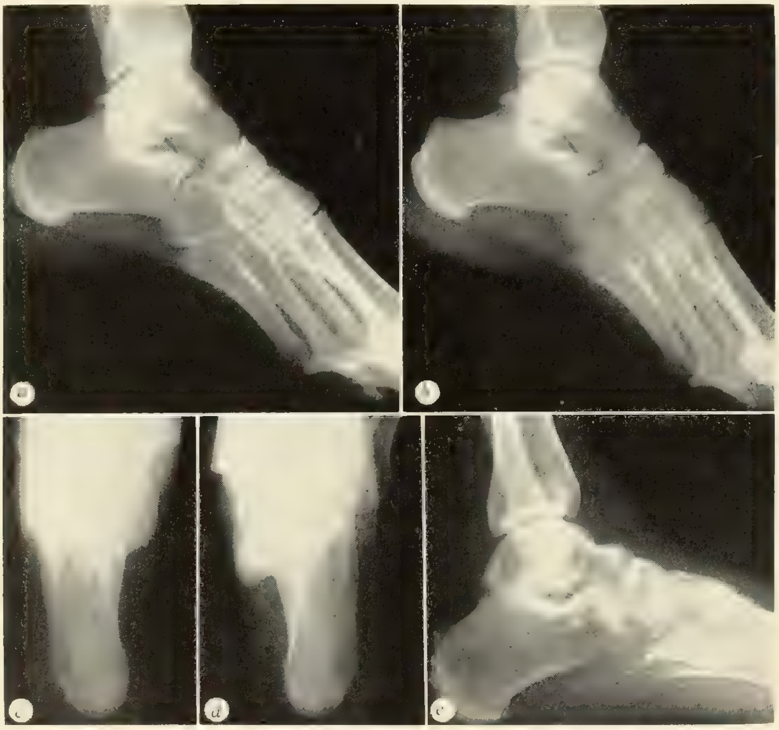

Fig. 5. Roentgenograms in case of calcaneotalar coalition in right foot (Case 1). *a*, Lateral roentgenogram of right foot; *b*, lateral roentgenogram of left foot: no change is evident in either *a* or *b*; *c*, sustentaculum tali-talar joint faintly visible in medial portion of left foot; *d*, obliteration of sustentaculum tali-talar joint of right foot; *e*, appearance of right foot one year after calcaneotalar arthrodesis.

Like hypermobile flatfoot, tarsal coalition is congenital and produces symptoms in the teens. Fig. 3*a* shows the characteristic appearance of the feet in a case of tarsal coalition. This anomaly causes flattening of the longitudinal arch, a medial prominence of the tarsus in the region of the head of the talus, and ankle valgus. The arch of the foot is not affected by weight bearing. In Figure 3*b* one can see that the patient is unable to invert the foot. The patient illustrated has a complete bony coalition on the right or the shaved side but only a partial coalition on the left or unshaved side. Although the peroneal muscles and tendons appear tight, they are not in true spasm.

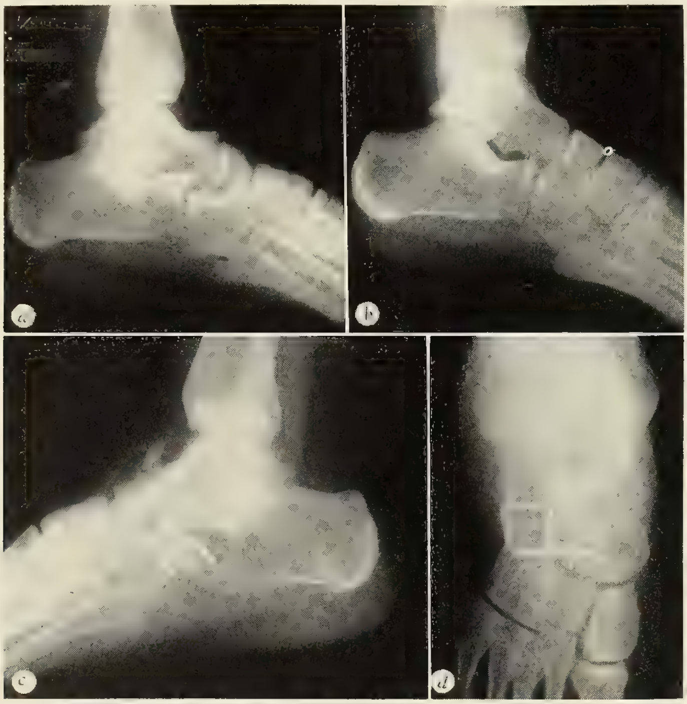

Fig. 6. Roentgenograms in case of calcaneotalar coalition in right foot (Case 2). *a*, Lateral roentgenogram of right foot showing spurring of supero-anterior lip of talus; *b*, lateral roentgenogram of left or normal foot; *c*, lateral roentgenogram of right foot made nineteen months after triple arthrodesis; *d*, anteroposterior roentgenogram of left or normal foot made at same time as the one shown in *c*.

In cases of tarsal coalition, roentgenographic examination is of real value if properly used. The presence of this anomaly always can be suspected on the basis of the clinical findings. If examination discloses rigid flatfoot, one should attempt to prove the presence of tarsal coalition by roentgenographic examination. Routine anteroposterior and lateral roentgenograms always will reveal the presence of calcaneonavicular coalition. Although routine roentgenograms sometimes will suggest the presence of calcaneotalar coalition, a special roentgenogram, which Harris and Beath[5] have designated the "coalition view" (Fig. 4), is necessary if the presence of this anomaly is to be proved. By the use of this roentgenogram, obliteration of the sustentaculum tali-talar joint can be demonstrated. In cases of calcaneotalar coalition, routine roentgenograms often will disclose spurring of the anterior-superior lip of the talus and a "fuzziness" of the subtalar joint, when

compared with similar roentgenograms of the opposite or normal foot.

Treatment of rigid flatfoot should be directed toward the cause of the condition, which, except in a very few cases, is coalition of two or more of the tarsal bones. Triple arthrodesis usually is the treatment of choice. Calcaneotalar and talonavicular arthrodesis probably are inadequate. In addition, calcaneocuboidal arthrodesis should be performed. This was illustrated in one of our cases (Case 4), in which the patient had calcaneonavicular coalition. Most of the pain was centered in the region of the calcaneocuboidal joint, and the patient obtained complete relief of his pain when triple arthrodesis was performed. As in the treatment of disabling relaxed flatfoot, operation should not be undertaken until the patient has reached the age of ten or twelve years.

Report of Cases

Case 1.—A girl, aged eighteen years, came to the clinic because of pain in the right foot. The pain had been present for one year. Examination disclosed the usual signs of tarsal coalition including inability to invert the foot, a prominence on the medial portion of the foot, and flattening of the longitudinal arch. Lateral roentgenograms did not disclose any definite change in either foot (Fig. 5*a* and *b*). In a special roentgenogram ("coalition view") of the left foot, the sustentaculum tali-talar joint could be seen faintly in the medial portion of the foot (Fig. 5*c*). A similar roentgenogram of the right foot disclosed obliteration of this joint (Fig. 5*d*). The presence of calcaneotalar coalition was proved at operation. The calcaneotalar bridge was excised and calcaneotalar arthrodesis was performed. This procedure produced partial relief of the symptoms. Figure 5*e* shows the roentgenographic appearance of the foot one year after the operation. As our experience has increased, we feel that a better result would have been obtained if triple arthrodesis had been performed in this case.

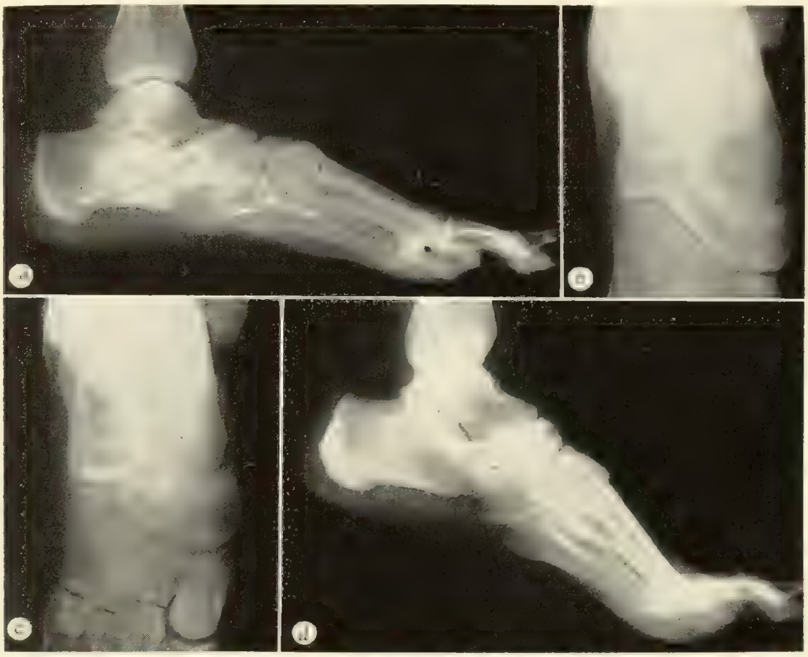

Fig. 9. Roentgenograms in case of calcaneonavicular coalition (Case 4). *a* and *b*, Lateral and anteroposterior roentgenograms of right foot showing bony coalition of the calcaneus and navicular; *c* and *d*, anteroposterior and lateral roentgenograms of left foot showing fibrous coalition of the calcaneus and navicular.

Case 2.—A girl, aged thirteen years, had had pain in her right foot for several years. Examination revealed a prominence of the medial part of the right tarsus and inability to invert the foot. A lateral roentgenogram of the right foot (Fig. 6*a*) disclosed a finding frequently observed in cases of calcaneotalar coalition, namely, spurring of the superior-anterior lip of the talus. It also revealed "fuzziness" of the subtalar joint when it was compared with a similar roentgenogram of the left or normal foot (Fig. 6*b*). The presence of calcaneotalar coalition was proved at operation. Figure 6*c* is a lateral roentgenogram of the right foot which was made nineteen months after triple arthrodesis was performed, and Figure 6*d* is a similar roentgenogram of the opposite foot which was made at the same time. At that time, the patient did not have any symptoms which were referable to the right foot and the appearance of the foot was good.

Case 3.—A boy, aged ten years, was brought to the clinic because of disabling pain which had been present in his right foot since he had fallen six months previously. Examination disclosed tarsal rigidity, medial prominence of the tarsus, and ankle valgus, which are the usual findings in cases of tarsal coalition. Anteroposterior and lateral roentgenograms disclosed a calcaneonavicular bar (Fig. 7*a* and *b*). Figure 8 shows the bar which was removed in the course of triple arthrodesis. The bar extended across the "sinus tarsi" in the usual manner and resulted in bony union between the calcaneus and navicular. When this paper was written, the patient did not have any pain in his right foot. Figure 7*c* and *d* shows the roentgenographic appearance of the foot twenty months after the operation.

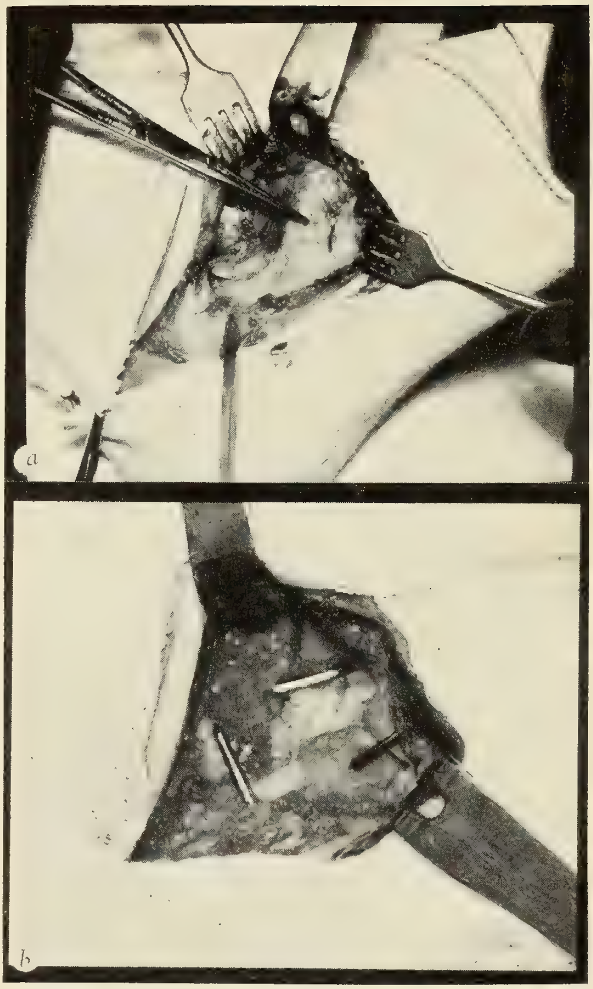

Fig. 10*a*, Calcaneonavicular bar filling "sinus tarsi" of right foot in Case 4; *b*, triple arthrodesis has been performed with metal staples and bone chips.

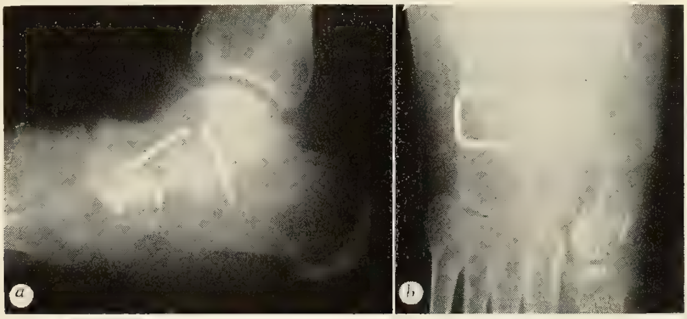

Fig. 11*a* and *b*, Lateral and anteroposterior roentgenograms of right foot made six months after triple arthrodesis in case of calcaneonavicular coalition (Case 4).

Case 4.—A man, aged twenty-four years, had had pain in his feet for ten years. The pain had been more severe in the right foot than it had been in the left foot. He had been rejected for service in the Army in World War II, and he had been unable to obtain regular employment. The appearance of his feet is shown in Figure 3*a* and *b*. Roentgenographic examination disclosed bony coalition of the calcaneus and navicular of the right foot (Fig. 9*a* and *b*) and fibrous or cartilaginous coalition of the same bones of the left foot (Fig. 9*c* and *d*). "Fuzziness" of the subtalar joint is more noticeable on the right side than it is on the left. Figure 10*a* shows the calcaneonavicular coalition at the time of operation. Triple arthrodesis was performed, utilizing metal staples for fixation (Fig. 10*b*). Figure 11*a* and *b* shows the roentgenographic appearance of the foot six months after the operation. Nine months after

THE COMMON HEMORRHAGIC DISEASES OF CHILDHOOD

ARMAND J. QUICK, M.D.
Milwaukee, Wisconsin

THE pediatrician is probably less certain in his approach to the hemorrhagic disorders than to almost any other group of childhood diseases. This is due largely to the inadequate and impractical presentation of the bleeding diatheses in standard textbooks, which in turn can be accounted for by the lack of a sound concept to explain the physiology of hemostasis.

The control of hemorrhage is so perfected that abnormal bleeding is relatively uncommon. When it does occur, it is due to either one of two basic causes: (1) a defective hemostatic response following injury of a blood vessel, or (2) a hyperpermeability of the capillaries. The first is generally the result of faulty coagulation or more explicitly of an inadequate formation of thrombin. The second is due probably to one or more unknown agents or factors that affect the permeability of the capillaries. Blood is lost by diapedesis and it manifests itself as purpura, which involves principally the skin and mucous membranes.

Hemorrhagic Disease Due to Defective Coagulation

It is now being gradually recognized that the coagulation mechanism consists of at least three separate steps or reactions which can be expressed by the following equations:

Thromboplastinogen + platelet activity = thromboplastin
Thromboplastin + calcium + labile factor + prothrombin = thrombin
Fibrinogen + thrombin = fibrin.

It is important to emphasize that one important reaction not expressed in these equations is the labilization of platelets by thrombin which brings about a chain reaction designated as the thrombinogenic cycle. The lysis of platelets is not only essential for the formation of thrombin, but it also is responsible for the liberation of a vasoconstrictor which the writer considers the key agent in hemostasis. Whenever the formation of thrombin is diminished to the critical level, a bleeding tendency develops. The most important causes of decreased thrombin production are lack of platelets, thromboplastinogen, labile factor or prothrombin. On this basis a simple classification of the common hemorrhagic diseases due to defective coagulation can be outlined.

I. Hypothromboplastinemia
    A. Thrombocytopenia
    B. Hypothromboplastinogenemia
        1. Congenital (hemophilia)
    C. Anti-platelet activator.
II. Hypoprothrombinemia
    A. Congenital
        1. Type 1 (diminished free prothrombin)
        2. Type 2 (diminished free and total prothrombin)
        3. Type 3 (diminished labile factor)
    B. Acquired
        1. Dietary deficiency of vitamin K
            a. Hemorrhagic disease of the newborn
            b. Diarrhea
        2. Faulty absorption of vitamin K from intestine
            a. Congenital atresia or absence of biliary ducts
        3. Toxins (dicumarol, salicylates, et cetera)

Thrombocytopenia

Since deficiency of platelets is generally associated with purpura, it will be discussed under that heading.

Hypothromboplastinogenemia (Hempohilia)

Thromboplastinogen which is the precursor of thromboplastin is a constituent of the plasma. Normally its concentration is sufficient to supply enough free thromboplastin to activate most of the prothrombin of the blood. By measuring the prothrombin remaining in the blood after coagulation under standardized conditions, the concentration of thromboplastinogen can be quantitatively estimated. This procedure is called the prothrombin consumption test.

In hemophilia a congenital lack of thromboplastinogen is present at birth and apparently remains unchanged throughout life. In severe hemophilia, only a trace of this clotting factor is present in the blood, whereas in the milder cases the concentration is higher but still below the minimum requirement for effective hemostasis. Changes in the apparent severity of the disease

From the Department of Biochemistry, Marquette University School of Medicine.
Read at the annual meeting of the Minnesota State Medical Association, Duluth, Minnesota, June 13, 1950.

and the occurrence of bleeding episodes do not appear to be caused by changes in the basic defect, but by a secondary factor such as an alteration in the vascular response which is superimposed on the primary deficiency.

On the basis of this concept of hemophilia, both the diagnosis and treatment can be rationalized. In the past the diagnosis depended on a history of heredity, a prolonged coagulation time and a bleeding tendency. Since a positive family history is obtainable only in about one-half of the cases, and since the other two findings are not specific for hemophilia, it is easy to see that the diagnosis was far from exact; and since the clotting time in mild hemophilics is only slightly prolonged many cases assuredly remained undiagnosed. With the development of the prothrombin consumption test which measures the amount of prothrombin remaining in the serum after coagulation, a specific diagnostic procedure for hemophilia became available. This test measures the available thromboplastin of the blood. When normal blood clots, little prothrombin remains in the serum; whereas when hemophilic blood clots, little thromboplastin is available and therefore little prothrombin is consumed; hemophilic serum as a consequence still contains a high concentration of prothrombin. In severe hemophilia the serum prothrombin time is as low as eight seconds and the hemophilic range is eight to fourteen seconds whereas the normal range is eighteen to thirty seconds.

A low prothrombin consumption time with a normal platelet count and a normal plasma prothrombin time, makes the diagnosis of hemophilia almost certain. The one important condition which is not ruled out is the hemophilic-like disease which is caused by the presence of a plasma factor which apparently inhibits the platelet activator of thromboplastinogen. This disease which is rare in childhood will be briefly discussed later.

The nature of the bleeding tendency in hemophilia is helpful in the diagnosis. Abnormal bleeding following circumcision should immediately arouse suspicion, and a persistent tendency to bruise always deserves careful study. Characteristically these bruises in hemophilia are actually small hematomas. Only when these hematomas are superficial, do they discolor the skin. The deeper hematomas can only be palpated and they are occasionally mistaken for abscesses.

The severe case of hemophilia with a positive family history and a markedly prolonged coagulation time offers no diagnostic problem; but the mild case, with a negative family history and a coagulation time that is nearly normal even when done meticulously, could not be diagnosed with any degree of certainty until the prothrombin consumption test was developed. But it is the mild case that deserves particular attention since such an individual may without warning have severe hemorrhage from even a minor operation such as a tonsillectomy or the extraction of a tooth. Furthermore, a hemophilic, no matter how mild, transmits the defect to all his daughters and the severity of the disease in their offsprings is unpredictable.

The treatment of hemophilic bleeding should be guided by the basic fact that these patients rarely die from exsanguination but that the pressure effects from internal bleeding accounts for nearly all the injurious results. The bleeding usually comes from arterioles and small arteries.

The immediate therapeutic approach is local, and the important measures are cold, pressure and rest. Cold, preferably an ice bag, should be applied immediately after injury. By this means, the vessels in the injured area become contracted and the blood flow becomes diminished, thereby producing conditions favorable for stanching. Pressure likewise is exceedingly helpful in limiting bleeding; in fact, it appears fairly certain that most hemophilic bleeding is eventually stopped by the pressure exerted by the hematoma on the injured vessel. Complete rest obviously is indicated. It should be emphasized and re-emphasized that heat should never be applied to the area of bleeding, for it causes dilatation of blood vessels which accentuates the hemorrhage. One must be guarded in not mistaking a hematoma for a deep infection and then treating it with a poultice and heat.

By means of prompt local treatment hemarthroses may often be aborted or minimized. Much of the crippling in hemophilia can be prevented, but this requires education of both the physician and the parents. The treatment of deformed joints can often be benefited by physicotherapy.

The only known reliable systemic treatment is blood transfusion. By this means thromboplastinogen, which the hemophilic blood lacks, is supplied, and the hemostatic efficiency is temporarily increased. Transfusions are far more efficient prophylactically than curatively. In fact a patient properly prepared with a large plasma transfusion may undergo major surgery without abnormal bleeding. Fresh plasma is preferable to whole blood since it is twice as effective and can be given repeatedly and in large volumes.

Transfusions should not be given indiscriminately, but only when local measures have failed or when a patient is prepared for an operation. There is suggestive evidence that transfusions may cause the formation of an inhibitory agent in the blood which apparently acts on the platelet activator. The condition thus produced will be discussed in the following section.

Hemophilic-like Disease

The disease is very similar to hemophilia clinically as well as regards laboratory findings. The coagulation time is prolonged and the prothrombin consumption time is low. The disease can, however, be readily distinguished from true hemophilia by determining the effect on the clotting when the blood is mixed with an equal volume of normal blood. A mixture of normal and hemophilic blood will have a normal clotting time, while an equal mixture of hemophilic-like blood and normal blood will have a delayed clotting time. The disease is caused by a factor which inhibits the platelet activator of thromboplastinogen. As stated before, transfusions may cause the condition, and recently it has been found that plasma fractions are even more prone to induce the formation of this so-called "circulating anticoagulant." The disease is important because the hemostatic defect cannot be corrected by transfusions. It becomes necessary therefore in studying hemophilic blood to determine what effect it has when mixed with normal blood. Hemophilia may be complicated by the coexistence of hemophilia-like disease, and when this occurs transfusions have no therapeutic efficacy. Fortunately the hemophilic-like disease is rare in children, and its production can be minimized by avoiding the injection of plasma protein fractions, and by giving blood or plasma transfusions only when urgently needed.

Hypoprothrombinemia

Deficiency of prothrombin may be congenital or acquired. There are three known types of congenital hypoprothrombinemia. To explain how this is possible, it is necessary to discuss briefly the new concept of the prothrombin complex. In human blood prothrombin is present partly in a reactive form and partly in a precursor state. Only free prothrombin can be converted to thrombin and this requires its interaction with thromboplastin, calcium and an agent discovered by the writer in 1943, which he named labile factor. This substance is closely related to prothrombin, and for convenience can be considered to be part of the prothrombin complex. In one type of congenital hypoprothrombinemia, both the free and total prothrombin levels are low; in the second the free prothrombin is diminished but the total is normal; while in the third the labile factor is deficient. Clinically these three conditions are very similar to hemophilia but can readily be distinguished by the prolonged prothrombin time. None of the three responds to vitamin K, but all can be temporarily corrected by blood or plasma transfusions. Since the labile factor is destroyed by storage, only fresh blood or plasma should be employed in treating the third type. The bleeding can often be controlled by the local measures which are effective in hemophilia.

The most important acquired type of hypoprothrombinemia for the pediatrician is the hemorrhagic disease of the newborn. The fetus is far more susceptible to vitamin K deficiency than the adult, and if the mother's nutrition is defective, the newborn child often develops a marked hypoprothrombinemia during the first few days of life. During this period the baby is a potential bleeder protected only by the intactness of its vascular system. Any trauma may precipitate a hemorrhage which may lead to dire results if prompt combative measures are not immediately instituted. A plasma transfusion becomes effective immediately, and vitamin K given intravenously restores the prothrombin level in four hours. By supplying the mother with a few cents worth of vitamin K during the last week or two of pregnancy, the hypoprothrombinemia of the newborn can be almost completely abolished. It is a pity that a few physicians belittle the efficacy of vitamin K. Anyone who has seen a fullblown case of hemorrhagic disease of the newborn saved only by prompt and heroic measures is willing to use vitamin K prophylactically even though only one baby in ten thousand may require this measure.

Obstructive jaundice, which is an important cause of hypoprothrombinemia in the adult, often causes little or no decrease of the prothrombin level of infants. The writer has seen a number of babies with complete atresia of the biliary ducts and complete absence of bile from the intestines for months without a significant drop in the prothrombin level. In persistent diarrhea vitamin K deficiency may occur. The use of antibacterial agents which sterilize the intestinal tract may accentuate the lack of vitamin K.

Certain drugs depress the synthesis of prothrombin and cause a drop in prothrombin sufficiently marked to cause a bleeding state. The most common group of compounds having this prothrombinopenic action are the salicylates. By improving the nutritional state of the child this danger can generally be averted. There is no justification for using a salicylate preparation fortfied with a synthetic compound having vitamin K activity.

Hypoprothrombinemia in childhood is not common, but the possibility that it may occur should never be ignored. Whenever there is a possibility for its occurrence, a prothrombin time determination will furnish the correct answer. The study of any bleeding condition is not complete unless this test is done. Therapeutically it is well to remember that vitamin K is only effective if a deficiency of this vitamin causes the bleeding condition. In all other conditions of hypoprothrombinemia, plasma or whole blood transfusions only are effective.

Thrombocytopenic Purpura

Purpura is one of the most common forms of hemorrhage in childhood and one of the most difficult to cope with. It seems fairly clear that there are two separate but closely related components that account for the hemorrhagic state. The two are the lack of platelets and a vascular factor. Thrombocytopenia alone does not cause a purpuric condition. On the one hand, one sees repeatedly in cases of lymphatic leukemia a platelet count of 10,000 or less with no signs of purpura and a normal bleeding or tourniquet test. On the other hand, purpura with typical petechiae may appear with a normal platelet count. Bleeding as a rule is more severe in thrombocytopenic than in non-thrombocytopenic purpura. It seems logical to conclude that the purpura is due to a vascular factor, the nature of which is not understood. If there is a co-existence of thrombopenia, a coagulation defect is superimposed, since the activation of prothrombin is very incomplete when the platelets are low.

The recognition of thrombocytopenic purpura offers no difficulties, but the vexing problem is finding the cause. Probably the most common occurrence is as a complication of an infectious disease, and frequently the severity of the latter bears no relation to the intensity of the purpura. A mild case of rubella or chicken pox may induce a pronounced thrombocytopenic purpura with profuse bleeding. Blood dyscrasias, especially acute leukemia, are often complicated by purpuric bleeding. Allergy and drug sensitivity can cause purpura, and it appears that the emotional state may have some influence. Depression of bone marrow causes a fall in the platelet count. In addition to these secondary purpuras, a number of cases remain in which no specific cause can be found. These are designated essential, primary or idiopathic.

The treatment of thrombocytopenic purpura remains uncertain. The majority of cases recover spontaneously. Usually transfusions are given, but other than restoring erythrocytes and hemoglobin, probably little benefit is obtained. In a few cases, the writer has found that folic acid appeared to diminish the bleeding tendency without affecting the platelet count. Toluidine blue and protamine are disappointing in acute thrombocytopenic purpura.

When to do a splenectomy remains a moot question. Since a spontaneous and permanent recovery is frequent in children, the removal of the spleen should never be considered impetuously. To be sure, it is a serious responsibility to manage a case of thrombocytopenic purpura since the possibility of a spontaneous cerebral hemorrhage is ever present, but it is to be remembered that a splenectomy in the acute stage is likewise not without danger. Before a splenectomy is performed, all possible causes should be ruled out, a period of several weeks allowed to see whether a spontaneous recovery may occur, and a careful bone marrow study be made. If the marrow is aplastic, no benefit need be expected from the operation.

Since the bleeding in non-thrombocytopenic purpura (the Henoch-Schönlein types) is usually much less of a problem than the other symptoms, no special measures generally are necessary to

(Continued on Page 1165)

DEPROPANEX IN POST-SURGERY

J. J. HEIMARK, A.M., M.D., Fairmont, Minnesota, and
R. L. PARSONS, B.A., M.D., Triumph, Minnesota

SINCE before the last war, the writers have been routinely using the deproteinated pancreatic extract, Depropanex, post-surgically. As is well known, this drug is used in cases where smooth muscle spasm is present. In renal colic where it has been used for a considerable time it, in conjunction with other sedation, has been observed by some to produce great relief. What prompted us to try Depropanex post-surgically was the observation that, before Depropanex was administered in renal colic, there was a very distressing paralytic ileus present; following Depropanex injections, this condition was very shortly improved and relieved. It was so impressive to us that we then wondered what Depropanex would do in patients with the same distressing condition following abdominal operations. We therefore decided to give Depropanex routinely to all our patients following operations. The first injection of 4 c.c. is given the surgical patient upon his return to his room, even before he is awake. A second dose of 4 c.c. is given in the evening. These two doses of Depropanex are then given routinely twice daily for three to five days, depending upon the progress and the condition of the patient, as well as on the type of operation performed. A patient having only the appendix removed may not need the Depropanex more than twice daily for three days, while one who has had both gall bladder and appendix removed is usually given Depropanex for four to five days. The same applies to other major abdominal operations.

Now that approximately a decade has passed during which time we have used Depropanex post-operatively, we feel that the results have been so uniformly encouraging that it warrants a report on what we have experienced. Before we go into the details of what we have observed, we wish to state that we have been most fortunate in having an anesthetist who was trained for a year at the University of Minnesota Hospitals in Minneapolis. The anesthesia she has used almost exclusively for induction is Penthothal Sodium, followed by Cyclo-Propane gas. Curare has also been used to overcome peritoneal spasm and tension.

In acute gallbladder colic, Depropanex in conjunction with sedation has been found to be efficacious in relieving the spasm, pain and distress, as it does in renal colic. Following gallbladder surgery, it is reasonably safe to assume that Depropanex will reduce the spasm in the common duct as well as in the sphincter of Oddi. Relieving this spasm will, in turn, relieve the bile back-pressure created in the liver, ducts, and on the cystic stump. This relief of spasm, with resultant early flow of bile, is definitely an adjunct in the smooth recovery of the patient. The diminution of nausea and vomiting in these cases leads us to conclude that Depropanex is the aiding factor in this smooth post-operative recovery.

But the outstanding improvement we have observed on patients routinely given Depropanex post-operatively has been the control of paralytic ileus. The abdomen remains uniformly soft all through the critical post-operative days. When gas pains begin, the patient states that the pain will travel along in the bowel as if he had taken a laxative, and the gas pain never becomes distressing. There does not appear to be any noticeable abdominal distention; the abdominal wall does not feel tense nor rigid; the distressed facies is absent; the patient tolerates sips of water and invariably impresses us as being comfortable. When an enema is given on the third day the nurses report good results, while rarely do they have to use a rectal tube to siphon off the enema. On various occasions we have stopped the Depropanex to observe what takes place. The following day the patient will complain of distressing gas pains, but when we give Depropanex again, the gas pain soon becomes relieved and begins to move on in the bowel.

The above results have led us to speculate on the physiological action of Depropanex. It is advertised as relieving spasm. But we are wondering whether, if it relieves spasm, it does not also supply the smooth muscle with something that brings about a normal tone and natural power which thereby overcomes the muscle weakness which may eventually lead to a paralytic bowel with resultant distention? This uniformly good tone to the bowel all through the post-operative period has led us to notice that there is less vomiting as well as less acute dilatation of the stomach which ordinarily follows all types of operations, especially the major ones. Rarely do we resort to the nasal suction apparatus, and since there is very little vomiting we do not need to resort to intravenous fluids. Since these two adjuncts have been practically eliminated in respect to these patients, it is an obvious economy to the patient, while the floor nurses are thereby given more time for their daily floor routine. The same is true for the time-consuming work and anxiety the paralytic bowel causes when repeated enemas must be given for relief, to say nothing of the distress the rectal tube and enemas cause the ailing patient. The rarity of these distressing complications naturally leaves the patient in a much-desired frame of mind during these post-surgical days. In fact, we have had some patients who have given us the impression by their silent looks: "When is the tough time following this operation going to strike?"

We encourage our patients to get out of bed as soon as possible post-operatively. Since they make such a smooth recovery, the distress by their so doing is not too great for them.

In summing up our observations on these patients to whom we have routinely given Depropanex following surgery, we have observed the following:

1. No ill after-effects from the use of Depropanex.
2. Practically a complete elimination of post-operative paralytic ileus.
3. Less nausea and vomiting; therefore, less dehydration and acute dilatation of the stomach.
4. A smoother, easier, more pain-free recovery; therefore, a less anxious patient.
5. Intravenous fluids seldom used; therefore, economy to the patient.
6. Nasal suction and repeated enemas eliminated; thus, less punishment for the patient.
7. Patients over fifty years make as smooth a recovery as do the younger ones.

We believe that the beneficial effect of Depropanex on patients throughout the post-operative period has been convincingly demonstrated.

Has this deproteinated pancreatic extract, Depropanex, been fully researched?

The authors are cognizant of the fact that others have found so-called "hypotensive" extracts such as Depropanex without demonstrable intrinsic therapeutic merit in the dosage and methods of administration recommended. (J.A.M.A., March 3, 1945, p. 522.) We are also informed of the fact that Depropanex has not been submitted to the Council on Pharmacy and Chemistry for approval. We have used this preparation, however, in post-surgery patients and feel it has been of definite therapeutic value. This report is made, therefore, in the hope that our experience may be of value to others.

FLATFOOT, WITH SPECIAL CONSIDERATION OF TARSAL COALITION

(Continued from Page 1097)

the operation, the patient was walking on his right foot and was not having any pain on the right. It is anticipated that a similar operative procedure eventually may have to be performed on the left foot.

Summary

There are three main types of flatfoot. The most common is an asymptomatic flattening of the longitudinal arch. This is an individual characteristic. The two types of symptomatic flatfoot are relaxed flatfoot and rigid flatfoot. Recent advance in the knowledge of rigid flatfoot seems to indicate that in most cases the feet are rigid because of coalition existing between the calcaneus and talus or between the calcaneus and the navicular.

THE ROENTGEN DIAGNOSIS OF SILICOSIS

EUGENE P. PENDERGRASS, M.D.
Professor of Radiology, University of Pennsylvania
Philadelphia, Pennsylvania

(Continued from the October Issue)

Pneumoconiosis and Silicosis Occurring in Various Industries

All of the roentgen manifestations that have been described above have taken into consideration the hypothesis that the lesions in many or all instances have been produced by free silica and modified by other dusts (contaminants). As stated before, it is probable that very few opportunities are afforded to study lung changes in which pure silica is the only dust present. One should therefore bear in mind that the manifestations of silicosis in the various industries are likely to be different. For instance, the roentgen findings in the slate and talc workers are likely to be different from those occurring in hard and soft coal miners. The roentgen findings may differ even in different foundries. In most instances it requires many years (six to fifteen) of exposure before one can demonstrate roentgen evidence of silicosis. The exceptions to this rule are classified under the head of "rapidly developing silicosis."

Rapidly developing silicosis has been described by Gardner.[27] When individuals are exposed to excessive quantities of finely divided silica, an unusual kind of reaction develops. The overwhelming deposits of silica seem to stimulate connective tissues in every part of the lung at the same time. The nodules are of microscopic proportions and in most cases there have been complicating infections.

I have seen a great many roentgenograms (some single, a few stereoscopic) of individuals who were diagnosed as having rapidly developing silicosis. In the advanced cases lobar consolidations, due largely to the superimposed infection, obscured the changes due to silicosis. In the earlier cases the roentgenographic manifestations were those sometimes observed in an interstitial type of pneumonitis of ill-defined shadows similar to that produced by a prominent pectoral fold. In a few cases in which I made roentgenoscopic observations, the costal and diaphragmatic excursions seemed to be limited. A number of the individuals that I saw had lost weight, were pale and dyspneic. Experience in this country was similar to that in England,[49] in that most of the fatal cases were associated with tuberculosis.

Another consideration having to do with silicosis is concerned with what might be called individual susceptibility. Physicians interested in this subject have noticed that not all individuals exposed to dust in the same industry, and apparently in the same manner, develop silicosis. Why such a difference is manifest no one knows. Many explanations have been offered, but none of them are completely satisfactory. Lanza[42] feels that the question of individual susceptibility has been overworked and is not as significant as the question of dust exposure (dosage). There seems to be a general agreement that when a tuberculous infection is present, the actions of the silica and the infection are enhanced.

Asbestosis

Asbestosis is the second of the recognized specific pneumoconioses. Since, however, its roentgen manifestations in no way simulate those occurring in silicosis, the criteria for its diagnosis are not reviewed.

Differential Diagnosis

Any exposition of the criteria applicable to the diagnosis of the specific pneumoconioses, and of silicosis in particular, must include other conditions which not infrequently make the problem of differential diagnosis extremely difficult. Some of these are so familiar as to require but brief mention; others, either because of their unusual interest or because of the frequency with which they are misdiagnosed as silicosis, will be considered in some detail.

First in order of consideration are the benign pneumoconioses, and second, the many pulmonary diseases productive of roentgen changes similar to those of silicosis but unassociated with the inhalation of dust.

The Non-specific Pneumoconioses

Under the heading "non-specific pneumoconioses," attention is directed to the pulmonary reactions resulting from the inhalation of all types of mineral dust which are incapable of stimulating within the lungs the development of progressive fibrosis. Anthracosis, siderosis, as well as the reactions to the inhalation of cement, gypsum, and the various silicates, with the exception of asbestos and possibly talc, are all included.

The alveolar phagocytes, regardless of the composition of the inhaled dust, tend to concentrate the particles within the lymphoid tissues of the lungs and mediastinum as well as in the areolar tissues about the perivascular lymphatic trunks. Excessive accumulations may excite a low-grade chronic inflammatory reaction which is non-progressive but which may be productive of small amounts of grossly invisible cellular connective tissue. The only secondary effect is the appearance of emphysema, microscopic in its proportions and of no clinical significance.[32] Roentgenographically there may be some increase in prominence of the normal linear pulmonic markings, but with the exception of those "roentgenologic conditions" productive of a pseudo-nodulation and resulting from the inhalation of inert but radiopaque dusts, no *specific* deviations from the normal can be identified. Increasing experience will doubtless lead to the recognition of others, but to date those in the latter category to receive consideration are baritosis, siderosis, and the changes occurring in silver polishers, and those due to the inhalation of tin oxide.

Baritosis, originally described by Arrigoni,[3] results from the inhalation of barium sulfate, and occurs chiefly among the baryta miners in Italy. I reported a small incidence among workers in a Pennsylvania plant.[55] In baritosis there is no respiratory incapacity, the only evidence of the presence of the mineral being the demonstration upon the roentgenogram of sharply circumscribed nodules evenly distributed throughout the lung fields.[56] Duplication of the condition in the experimental animal is unproductive of fibrosis, indicating that the nodulation demonstrable in roentgenograms results from the direct visualization of compact collections of radiopaque particles within the lungs.[32]

Siderosis, an analogous condition occurs as the result of a number of industrial processes, chief among which are electric arc-welding, metal-grinding, silver finishing, and possibly boiler-scaling. Collis,[8] in 1923, suggested that errors in the diagnosis of silicosis in iron miners might be made, due to the radiopacity of iron oxide. Subsequently, but without the benefit of clarifying pathological material, Doig and McLaughlin,[15] in 1936, reported the occurrence of fine nodulation in 6 of 16 electric arc-welders. In 1938, Enzer and Sander[18] described similar findings in 5 of 26 electric arc-welders, who had worked for an average of nineteen years using bare metal rods containing 99 per cent iron and 1 per cent free silica, and in one case presented necropsy findings to indicate that the roentgen changes were a direct consequence of the collection of radiopaque iron oxide particles within the lungs. Sander[69] states that Enzer has since obtained three additional and confirmatory autopsy cases.

In 1945, entirely similar roentgen findings were reported by Pendergrass and Leopold[56] in four of ten metal-grinders who had worked from twelve to seventeen years in a plant shown to be free of a silica hazard. The metal ground was used in the manufacture of bearings and was identified as chrome vanadium and chrome molybedenum tool-steel containing about 98 per cent iron, 1.8 per cent alloy, and 0.2 per cent silica. For the grinding process, artificial abrasive wheels, recognized as innocuous from the standpoint of a silica hazard and composed of bakelite, carborundum, and aluminum oxide, were used exclusively throughout the occupational lives of the affected persons.

More recently, the occurrence of identical roentgen findings in silver-polishers has been reported from England.[46] Quite pure and finely divided iron oxide in the form of either "rouge" or "crocus" is used in the final finishing of silver, and when applied to revolving "dollies" is productive of considerable dust, consisting primarily of iron oxide contaminated with metallic silver, the latter also being radiopaque. Four men, employed as silver-finishers for periods of twenty to forty years, were examined. Chest roentgenograms of all presented the changes to be described below, and a subsequent autopsy on one revealed only particulate collections of iron oxide with small amounts of silver within the lungs.

A similar condition has been described as occurring in boiler-scalers.[9,16,75] Here, however, there may be an associated silica hazard, the elimination of which is required before the changes seen can be properly attributed to siderosis.

Pathologically, in siderosis there is gross evidence of pigmentation, the ferrous nature of which may be demonstrated by proper staining. Histologic sections show the pigment to be distributed chiefly in the perivascular lymphatics, the subpleural spaces and the interalveolar septa. It is the heavy accumulation in the perivascular lymphatics of the iron oxide pigment, in itself radiopaque, which accounts for the roentgen findings. At no time have any reactive phenomena, provocative of fibrosis within the cells, been described.

The pulmonary changes in siderosis, as reflected in the chest roentgenogram, cannot from the film alone be distinguished from those already described in detail as occurring in simple silicosis. They are, therefore, simple of definition and consist of discrete nodular densities distributed uniformly throughout both lungs, without hilar enlargement but in some cases with an associated reticulation resulting from an increased prominence of the linear markings.

Pseudo-nodulation due to inhalation of tin oxide has been reported by Pendergrass and Pryde[57] and Barták et al.[4] Pendergrass and Pryde recorded a case which had been studied by Dr. Hollis E. Potter of Chicago. The patient was a man, aged forty-five, who had worked at a single job of bagging tin oxide for fifteen years. There was no disability. The roentgenogram showed diffuse dense pseudo-nodulation throughout both lungs similar to that observed in baritosis and considered to be a benign pneumoconiosis. Chemical analysis of the tin oxide showed it to be 96.5 per cent tin oxide, while the remaining 3.5 per cent contained aluminum, iron, and sodium. No silica was found. Experimental studies of the material placed in a dog's lung and in phantoms showed that its density was sufficiently great to produce shadows equal to or greater than those produced by iron. The pseudo-nodulation produced by tin oxide is not to be confused with the pneumoconiosis reported in the tin miners of Cornwall;[35] the industrial hazard among them was one of silicosis.

It seems quite obvious that a detailed occupational history is fundamental to the differential diagnosis of silicosis and the pseudo-nodular types of the benign pneumoconioses.

Talc Pneumoconiosis

It has already been indicated that the silicates, with the exception of asbestos and possibly talc, belong in the category of inert dusts. Asbestos, a fibrous silicate, is productive of a specific pneumoconiosis characterized by the formation of a progressive interstitial pulmonary fibrosis. Talc, also a silicate, with certain physical characteristics in common with asbestos, requires more specific evaluation (Hobbs.[39]).

The available experimental evidence would indicate that talc alone is incapable of producing a progressive fibrosis.[31,38] The criticism has been advanced, however, that the inhalation experiments were of insufficient duration to define conclusively the effect of long continued industrial exposure, this latter being fundamental to the development of specific changes.[73] Siegal reports no case with less than ten years' exposure, but then records an incidence of 14.5 per cent "talc pneumoconiosis."

Roentgenograms are described as showing a bilateral diffuse haziness or "ground-glass" appearance, with some tendency to parahilar and subapical localization, and, in some cases, with the presence of an ill defined nodulation and/or conglomerate areas of fibrosis leading to a suspicion, as yet unproved, of underlying infection.[62,73] Siegal[73] further directs attention to an occasional right-sided predominance and to a rarely demonstrable blurring or "shagginess" of the cardiac silhouette, reminiscent of asbestosis. He also describes in detail the occurrence of "pleural plaques," long associated with the inhalation of talc.

The similarity of the described roentgenographic manifestations to those of asbestosis is quite striking, but the occurrence of an asbestosis-like reaction following prolonged industrial exposure to talc would seem unlikely. Further controlled investigation, designed to eliminate the possible complicating factors of quartz-contaminated dust and infection, is, however, imperative before concluding with finality that the roentgen changes are the reflection of a specific and progressive fibrosis, and that talc is the sole etiologic agent in their production. In this regard, it seems quite probable that the described coexistent nodulation may be silicotic in origin. In the reported autopsy cases[62] there had been other opportunities for the inhalation of dusts presumably contaminated with silica, and in the mining of talc itself similar exposures have not been excluded.

Lung Changes Associated With Alumina Abrasives (Shaver's Disease)

This disease was first observed[71] in February, 1942, in a thirty-three-year-old man, who for a period of eight years was engaged in manufacturing an abrasive, the main ingredient of which was bauxite. Since that time Shaver[72] has observed thirty-four well-established and thirty-eight early cases of lung involvement associated with the industry.

Occupational History.[71]—The process involved has been in operation for years and was believed to be innocuous. No one before had been discovered suffering with unusual lung involvement resulting from or associated with their occupation.

The abrasive being manufactured is *corundum.* It is an aluminum oxide of great hardness which is used as an abrasive.

The processing is done in electric arc furnaces. The material being treated consists of a mixture of bauxite, iron and coke. The bauxite is ground and mixed with other ingredients and then shoveled into large metal pots. The electrodes are lowered into the pots and the material is fused at temperatures of approximately 2000°C. During operation dense fumes are elaborated. The fumes contain alumina and silica and other materials in a finely divided state ($Al_2 0_3$ 50 per cent and $Si 0_2$ 35 per cent).

Symptomatology.—The symptoms are varied but *dyspnea* is the most outstanding. Sudden attacks of extreme breathlessness are frequently described. There is a history of cough and a frothy sputum.

In the advanced cases, substernal discomfort and tightness of chest, and occasional pleuritic type of pain is described. Weakness, fatigue and sleeplessness are associated with advancing dyspnea.

Physical Findings.—Most cases have weight-loss associated with a loss of appetite. The chest signs vary with the presence or absence of pneumothoraces. Cyanosis, limited chest expansion, harsh breath sounds, variable rales and tachycardia are some of the signs found.

Pathology.—Overwhelming fibrous tissue formation, alveolar wall thickening and profound emphysema are characteristic findings.

Roentgen Findings.—In well-established cases, a widened mediastinal shadow may partially obscure the shadows of the hila. The domes of the diaphragm are usually irregular. The domes may be elevated and tented. The distortions of the mediastinum and diaphragm become less marked and may disappear when pneumotherax occurs.

Lace-like granular shadows occur bilaterally in the upper halves of each lung, especially pronounced toward the hila. Conglomerate shadows are seen in the more advanced cases. In advanced cases, emphysematous blebs are seen. Pneumothorax, either unilateral or bilateral, and, with or without a pleural collection not infrequently occurs.

Vanadium Pentoxide

There is another industrial disease due to the *toxic effects of vanadium pentoxide.*[82] I have no personal experience with this but a short discussion is included for completeness.

Vanadium is a silvery white metal rarely encountered in its pure state. The ores are distributed mainly in Peru, South Africa, and Rhodesia.[82] The chief uses of vanadium are to raise the hardness and malleability of steel and to increase its fatigue-resisting properties. Vanadium pentoxide, a yellowish red powder, is used as an oxidizing agent in the conversion of naphthalene to phthalic anhydride and in place of platinum in the modified contact process of sulfuric acid manufacture.[82]

It had long been known that vanadium pentoxide dust would cause bronchitis among workers, but the full significance of the condition was not appreciated until the report of Wyers[82] appeared. He has observed at least fifty workers, men and women, some of whom showed reticulated shadows in the lower lung fields. It is not known whether these shadows are due to accumulation of dust in the air sacs or fibrosis. Vanadium workers complain of paroxysmal cough and pains in the chest, and have a tenacious sputum, which may be blood-streaked. They may develop emphysema. Other signs of the condition are those of systemic intoxication, which may be evidenced by diarrhea, anorexia, emaciation, visual defects, paralysis, vertigo, and convulsions.

Other and Confusing Clauses of Nodular Densities Within the Lungs

Tuberculosis.—Tuberculosis, following an hematogenous dissemination, presents on the roentgenogram evenly distributed nodular densities throughout both lungs, occasionally indistinguishable from those occurring in simple silicosis. Except in these cases, difficulty in the differential diagnosis between tuberculosis and silicosis seldom occurs, but in them the distinction must be made upon the basis of history, physical examination, and laboratory findings. Frequently an additional aid is the identification, in tuberculosis, of an accompanying localized infiltrate or cavity, without, however, evidence of conglomerate fibrosis of the type already described as occurring in tuberculo-silicosis.

Histoplasmosis.—Darling,[10,11,12] in 1906 and 1907, recorded three cases of a generalized and fatal protozoan infection, subsequently identified as histoplasmosis, which produced pseudo-tubercles in the lungs and areas of focal necrosis in the liver, spleen, and lymph nodes. Further reports[7,41,50,52,66,67,81,83] in more recent years have shown the disease to be world-wide in distribution, but most common in the east-central portion of the United States; have adequately documented its pathology and clinical course; and have offered evidence in support of the thesis that it is not invariably fatal but that it in all probability exists most commonly in a benign and asymptomatic form. DeMonbreun[13] in 1932 proved its fungous origin by identifying *Histoplasma capsulatum* as the causative organism.

The symptoms of histoplasmosis, when it is clinically manifest, are protean, being those of a generalized infection of the reticulo-endothelial system, for which Meleny[47] suggests the name "reticulo-endothelial cytomycosis." Of primary interest in this presentation, however, is the 20 per cent[41] occurrence of significant lung lesions. In some of these the roentgen findings closely simulate those of pulmonary tuberculosis, consisting of apical infiltrations with or without cavity; in others, miliary lesions 5 to 15 mm. in diameter are evenly distributed throughout both lungs. It is these latter which may resemble silicosis, and make necessary the inclusion of histoplasmosis in the differential diagnosis of the nodular pneumoconioses.

Also, in the areas endemic for histoplasmosis, the incidence of "disseminated miliary calcifications" is relatively more frequent than in the country at large.[43] While in such cases the nodules characteristically vary slightly in size, are of irregular distribution, and lack an uncalcified periphery, their appearance is such that they may rarely require differentiation from silicosis with central calcification of the nodules.

The Mycotic Infections.—There are a number of conditions, such as fungus infestations, that may simulate the various manifestations of silicosis. One of the important points in arriving at the diagnosis is for the radiologist to bear these in mind. Some of the more frequent infestations seen by us are mentioned.

In *moniliasis,* in which the chief pathogen has been found to be *Monilia albicans,* the roentgenogram shows irregular areas of infiltration which tend to become nodular. The appearance is similar to that in simple silicosis with nodular predominance. Fawcitt[23] has called attention to finding bronchomycoses as a complication in hematite iron-ore workers.

Sporotrichosis is due to a Streptothrix. In the cases that we have observed, the appearance is identical with nodular silicosis.

The roentgen appearance in *actinomycosis* may be that of a bronchopneumonia. The process may be diffuse or localized to one lobe. It may be confused with silicosis with infection.

It is sometimes difficult to establish the true diagnosis of a fungus disease, but every effort must be made to exclude the lesions that simulate silicosis before making a definite diagnosis of the latter.

Pulmonary Hemosiderosis.—Pulmonary hemosiderosis clearly demonstrable in roentgenograms as diffuse nodulation,[2] similar to that produced by silicosis, is said to occur in some patients with mitral stenosis.[56,59,70] Scott,[70] in an excellent paper, has discussed the subject in detail and has shown, I believe, that hemosiderin is responsible for the shadows in the roentgenograms. In our patients there was a preceding rheumatic fever. The shadow pattern is similar to that produced by silicosis or the pseudo-nodulation of benign pneumoconiosis.

Polycythemia Vera.—Polycythemia vera in patients with cyanosis and vascular engorgement may present a markedly increased prominence of the vascular shadows in the lung. Vessels seen in an axial plane simulate the nodulation found in silicosis. There are other shadows in polycythemia vera of unknown origin which simulate the shadows produced by conglomerate fibrosis. The history, physical examination, and blood count will assist in the differential diagnosis.

Carcinoma of the Lung.—Carcinomatous metastases may resemble the nodular and conglomerate shadows of silicosis with and without infection. Primary carcinomas arising in the gastro-intestinal tract and kidney tumors account for the great majority of such metastases, but carcinomas arising from other sites may be responsible. Here again the history and clinical findings should assist greatly in determining whether a malignant process is responsible for the abnormal shadow pattern.

Recently we have had two cases that were diagnosed primary carcinoma of the lung on the basis of a roentgen finding of an isolated mass shadow within one lung. There was a history in each instance that the patient was a hard coal miner for years. The only clinical history of significance was hemophysis. In one patient the lung lesion was due to a carcinoma, in the other, silicosis.

Mediastinal Enlargement.—In many silicotic patients, there are massive shadows that coalesce with the mediastinal shadow. On the single posteroanterior roentgenogram, the appearance simulates that produced by lymphoblastoma. I have no doubt that many of these patients have been treated for a malignant process. These massive shadows adjacent to the mediastinum, may be due either to massive lesions in the apices of the lower lobes or to massive lesions in the upper lobes which have migrated to the mediastinum.

Boeck's Sarcoid.—Boeck's sarcoid is primarily a systemic disease, classically presenting widespread involvement of the lymph nodes, viscera, osseous system, and skin. Commonly, however, its clinical manifestations occur in various combinations, leading to its separation into types, as the uveoparotid fever of Heerfordt and Mikulicz's syndrome. Similarly, there is a fairly large group —seventeen in Reisner's series of thirty-five cases[64]—in which associated lymphadenopathy and pulmonary involvement constitute either the most conspicuous or the only discernible manifestation.

The manifestations in chest roentgenograms are in turn extremely variable as to extent, distribution, and character, depending largely upon the phase of evolution of the disease process at the time of examination. For convenience of description, and without implication that the process is at any time static, both Reisner[64] and Bernstein[5] have subdivided the roentgen findings into several types. In attempting to identify the various forms of the disease, a free use of both classifications is made.

1. In some cases the only abnormality demonstrable on the roentgenogram is a bilateral, usually symmetrical enlargement of hilar and tracheobronchial lymph nodes.
2. The so-called "miliary sarcoidosis" is characterized by the presence of widespread nodular densities throughout the lungs which are usually quite uniform in size and distribution, but may at times exhibit a moderate tendency to coalesce and be most dense in the middle thirds. Commonly there is easily demonstrable hilar lymphadenopathy but, depending upon the phase of the disease, this may or may not be present.
3. A third group includes those cases in which there is hilar lymphadenopathy together with a string-like infiltration radiating outward from the hila into the pulmonary parenchyma. These string-like shadows appear perivascular in distribution and may be combined with a generalized nodulation such as has already been described.
4. A fourth type presents roentgenographically diffuse parenchymal infiltrations visualized as well demarcated but irregular and often contracted areas of increased density, having the appearance of fibrosis. Hilar lymphadenopathy is a variable finding, as is an associated background of increased linear markings and nodulation.

In all forms of this disease the pathological lesion is the non-caseating tubercle. The clinical course, however, is variable though inevitably chronic. The first and second types above described may represent an early and reversible stage, and both show a pronounced tendency to resolution. King[40] has reported complete clearing within an average of twenty-two months in twenty-three of thirty-seven cases of pulmonary sarcoidosis, but does not specify the type of involvement. In the third and fourth types the changes are at least partially irreversible. Some degree of resorption may occur, but there inevitably remains a residuum of increased linear markings and at times a massive contracting fibrosis. The latter leads to varying degrees of disability, and in some cases to a fatal termination, the commonest causes of which are the development of or transition into a typically caseating pulmonary tuberculosis or the development of cor pulmonale.[34,64]

The roentgen appearance of Boeck's sarcoid and certain of the pneumoconioses, including silicosis, is occasionally identical. The nodulation in the miliary form may be indistinguishable from that of silicosis and the pseudo-nodular types of the benign pneumoconioses, and the late fibrous reactions may rarely simulate the picture of tuberculo-silicosis. In all such cases, the differentiation rests upon a critical evaluation of the historical, clinical, and laboratory data. The distinction, however, is usually not difficult, since in sarcoidosis one is commonly led to the correct impression by the presence of marked lymphadenopathy, by irregularities in the distribution and character of the pulmonary lesions, or by the presence of other and extrapulmonary lesions.

Chronic Pulmonary Granulomatosis in Beryllium Workers.—The recognition of a new pulmonary disease appearing in workers engaged in certain industrial processes requiring the use of beryllium, or one of its compounds, is attracting increasing attention. This condition may present in the roentgenogram a pattern strikingly similar to that seen in silicosis. Affected individuals have, as a rule, been employed in the manufacture of fluorescent lamps, fluorescent powder, neon signs, or beryllium copper alloys, or have been engaged either in the extraction of beryllium from the ore or in projects of a research nature requiring the use of its compounds.

At least two rather distinctive and entirely different reactions have been described. The first of these, with which Van Ordstrand and his associates[76] in Cleveland have had the widest experience, is an acute chemical pneumonitis. Its roentgenographic characteristics, however, are entirely different from those of silicosis and require no elaboration in a discussion of the differential diagnosis.

The second type of reaction, recently labeled at the Sixth Saranac Laboratory Symposium as "chronic pulmonary granulomatosis occurring in beryllium workers," has been well described by Sosman and Wilson in a report from Hardy and Tabershaw,[36] by Pascucci,[53] and more recently again by Wilson,[80] and by Robert.[68] Its roentgen manifestations are extremely protean and for adequate description require some attempt at classification. As a consequence, two[53] or three[36] types or stages—granular, reticular, and nodular—are recognized. Granting the possibility that the various bizarre forms of the disease may represent different phases in its evolution, subdivision into types rather than stages would seem wiser until more extended observation enables us to detect a certain general pattern in the developmental cycle. To date, in most cases one is unable to demonstrate a distinct transition from one form to another, and there is no clear-cut gamut of stages through which any given case must pass. In contradistinction, there is some indication, as yet meager, that the types now recognized are all late manifestations and that, prior to the development of chronic granulomatosis, there may be a preliminary and perhaps transitory stage comparable to the acute form but so mild in degree that it escapes recognition.

In all types, the involvement is diffuse throughout both lungs. The granular form presents a generalized stippled or "fine sandpaper" appearance suggestive of pulmonary edema, but closer inspection demonstrates that the changes are distinctly particulate in nature. There is usually no accompanying hilar node enlargement. In certain instances this granularity may serve as a background for a generalized reticulation, comprising the reticular form of Sosman and Wilson.[36] In these there may be an accompanying slight to moderate enlargement of the hilar lymph nodes.

The nodular type, which is of primary concern in the differential diagnosis of silicosis, is characterized by the presence on the roentgenogram of evenly distributed nodular densities throughout the lungs. These vary from 1 or 2 mm. to 4 or 5 mm. in diameter in different persons, but in a given case are generally uniform in size. The tendency to coalescence is usually not well defined, although in some cases there may be a quite definite concentration of the nodulation in the upper lung fields. The hila are frequently indistinct, and may be the site of a pronounced lymphadenopathy.

At the risk of digressing, a brief résumé of the symptoms and clinical course of this so recently recognized disease is offered. Dyspnea, cough, and weight loss, together with a long latent period varying from months to several years prior to onset, are cardinal features. A study of the ventilatory function in advanced cases reveals marked respiratory incapacity, which is in turn regularly accompanied by a secondary polycythemia. Hardy and Tabershaw,[36] report a mortality rate of 35 per cent, but the outcome is not invariably fatal, and some of those cases which it has been our privilege to follow have remained relatively stationary over a period of several years, while others have shown varying degrees of improvement. Too short a time has elapsed to warrant final conclusions, and the ultimate result to be expected in the non-fatal cases is still a matter of conjecture. In any given case, however, attention should be directed to the fact that there is apt to be a striking lack of correlation between the clinical and the roentgen findings.

In autopsy material there is grossly apparent a diffuse thickening of the alveolar septa, usually most marked in the hilar portion of each lobe. Microscopically this is seen to have occurred secondary to a widespread cellular infiltration by macrophages and lymphocytes, with the associated formation of focal lesions in which there has been an obliteration of the alveolar spaces. Multinucleated giant cells of the Langhans' type are usually demonstrable, and the irregular deposition of fibrous tissue within the lesions is a common occurrence.

As long as the granularity so characteristic of the granular and reticular forms of the disease persists, the differentiation of the various nodular pneumoconioses from chronic pulmonary granulomatosis of the type seen in beryllium workers does not present a difficult problem. In the nodular form, however, the roentgen appearance may simulate exactly that of siliocisis and those benign pneumoconioses which exhibit a nodular predominance. In these cases recourse must again be taken to the occupational history and to consideration of the clinical and laboratory findings.

Comment

The remarks above are but a brief account of the story of silicosis and some of the conditions with which it may be confused. There are many avenues of research concerning silicosis still to be explored. The new work of Evans[19] in this country and Barták et al[4] in Italy may provide new approaches to this exceedingly important subject. Every year brings new answers to old problems and new problems to be answered. Until we know the answers to all of the problems concerned with this subject, it behooves us to plan for the worker. Such a plan should include the following requirements:

1. A healthy atmosphere in which individuals work.

2. Preemployment and annual physical and roentgen examinations of the chest in order to demonstrate early tuberculous lesions and exclude such individuals from participating in work that may be harmful to them and their fellow workers.

Summary

1. Attention is directed to the fact that a fluoroscopic and roentgenographic examination of the chest is the most precise method available for demonstrating in the living individual the pathological changes produced within the lungs by the silicosis. The necessity, however, for correlating the roentgen findings with all other essential data before making a definite diagnosis is emphasized.

2. The roentgen manifestations of simple silicosis and of silicosis complicated by the presence of coexisting infection, are detailed. The demonstration upon the roentgenogram of a generalized nodulation throughout the lungs is considered as fundamental to tht diagnosis of silicosis.

3. The differential diagnosis of silicosis and other conditions which may be productive of nodular densities within the lungs is reviewed.

Case Report

INFANTILE CORTICAL HYPEROSTOSIS

HAROLD W. HERMANN, M.D., AMES W. NASLUND, M.D., and ARTHUR E. KARLSTROM, M.D.
Minneapolis, Minnesota

IN July, 1945, Caffey and Silverman[3] made a preliminary report of four cases with a syndrome they designated infantile cortical hyperostosis. We wish to report another case believed to be of the same clinical entity.

Case Report

M. R., a baby girl, was born at term on January 4, 1950, after a normal spontaneous labor and weighed 7 pounds 2½ ounces. The gestation was accompanied by a mild hyperemesis on the part of the mother in the first five months with consequent dietary restrictions. The last four months antepartum were uneventful and without disease.

The infant was healthy and gained normally the first three months at home. Ascorbic acid and Drisdol had been added at one month. At three months the child was noted to be very irritable and anorexic. Soon thereafter, the parents noted a swelling of the right cheek. There was no known fever at this time. In spite of penicillin therapy, the hyperirritability and mandibular swelling persisted for nearly one month, then receded.

Before the mandibular swelling had disappeared, the irritability and anorexia again returned, followed by swelling of the right forearm.

The infant was first seen at our office on July 27, 1950, which was a few days after the left forearm had noticeably enlarged. The mandibular swelling was scarcely palpable, whereas the forearms were tensely swollen and tender. There was no hyperemia or discoloration of the areas involved. They were not fluctuant.

The child moved her arms slowly and infrequently. She cried when the swollen areas were palpated. Examination of the heart and lungs was negative. The spleen and liver were not enlarged. There was no adenopathy. Rectal temperature was 100.4°F. There were no palpable abnormalities of the thorax or lower extremities.

Laboratory examination revealed a hemoglobin of 55 per cent with 3.03 million red cells. The white count was 11,800 with 33 per cent polymorphonuclear cells, 60 per cent lymphocytes, 4 per cent monocytes and 3 per cent eosinophils. The urine was normal. Sedimentation rate was 8 mm. per hour by the Westergren method. Serology and Mantoux (1:1,000 dilution) were negative. Serum calcium was 9.8 mg. per cent and phosphorus was 5.6 mg. per cent. Alkaline phosphatase was 23.0 King-Armstrong units. Blood ascorbic acid level was .99 mg. per cent.

Roentgen examination revealed massive hyperostosis in the bones of both forearms and moderate hyperostosis of the right mandible. There was no other area of involvement discovered from complete skeletal films. Lung fields were clear and heart size normal.

Mandible films of a three-year-old sibling were also normal.

As of November 9, 1950, the previous areas of hyperostosis have returned to normal size without specific treatment.

Comment

The clinical features, laboratory data and x-ray findings of the case conform with those of cases presented by Caffey and Silverman[3] and Smyth, et al.[12] Basic features are hyperirritability, fever, and roentgenologic evidence of external thickening of the cortex.

This syndrome is usually manifest during the first three or four months of life with the mandible most often the primary site of involvement. From there the distribution and magnitude of swellings varies greatly.

More recently Caffey[2] reported two cases which developed during the second year of life (eighteen months and twenty months). Neither of these young children had mandibular hyperostosis. Of a total of twenty-seven cases reported, the average age of onset is the twenty-fifth week.

The cause and pathogenesis remain undetermined. Bacterial infections, scurvy, rickets, trauma and neoplastic diseases appear to be excluded as causal agents.

Infection as an etiology, is supported by leukocytosis, fever and, in some cases, elevated sedimentation rate, but treatment with the sulfonamides or the antibiotics has met with no significant response. Ross et al[4] reported blood cultures and febrile agglutinations to be negative in ten cases. They also had complete virus studies by the National Institute of Health which all proved negative. Tuberculosis is ruled out by a negative Mantoux and roentgenological findings. Similarly syphilis is ruled out by serology. Also, biopsy specimens have not supported infection as a causal agent but simply show hyperplasia of normal lamellar bone.[10] X-rays fail to show similarity of this syndrome to scurvy or rickets. There is an absence of a zone of rarefaction beneath the epiphyseal line leaving the terminal segments of the shaft unaffected. Also, the age at onset, adequate vitamin C intake and lack of response to cevitamic acid speak against scurvy.

No noncomitant blood dyscrasias have been reported.

Neoplastic disease is ruled out by absence of sarcomatous lesions in reported biopsy specimens and the benign course followed by all reported cases.

Shuman[11] found the disease refractory to antihistaminic preparations and allergy elimination diets.

Delano and Butler[5] report a case occurring within ten days after a smallpox vaccination and postulated that infection was the basis somewhat similar to that of osteomyelitis variolosa. In most of the reported cases, however, there has been no history of antecedent vaccination or immunizations.

There was no evidence of a hereditary factor in this case or previous reported cases except for that of Van Zeben[15] who suggests the possibility in a description of three patients in one family with typical periosteal lesions.

Sherman and Hillyer,[10] in an extensive review of the syndrome in February, 1950, found only twenty-seven

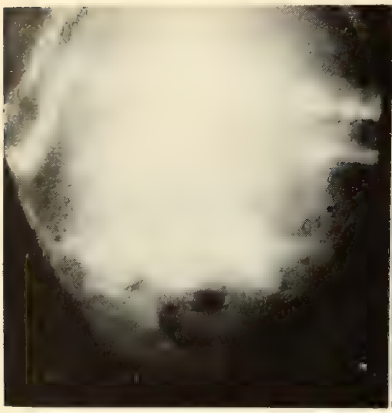

Fig. 1. Showing thickening and increased opacity of right mandible.

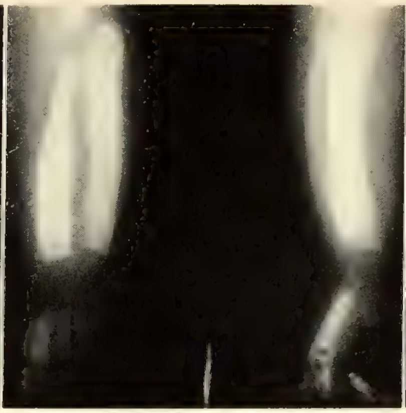

Fig. 2. X-ray of right forearm showing a thickening of both radius and ulna.

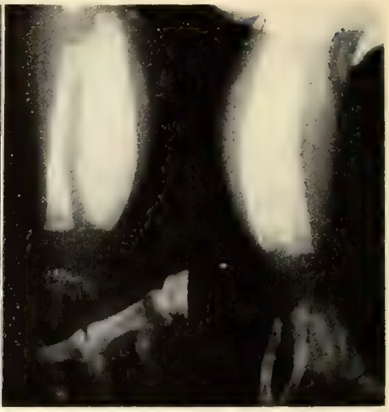

Fig. 3. X-ray of left forearm showing a marked thickening of left ulna alone.

cases reported, of which fifteen were males and twelve were females. There was no preference of race or geographical location. They postulated that the initial disturbance was of the muscle tissue with secondary stimulation of periosteum. Supporting their theory is the lack of periosteal inflammation or hemorrhage and presence of vascular changes and degeneration of overlying muscles.

The soft tissue changes causing tenderness and pseudoparalysis appear to be limited to the muscle groups adjacent to the involved bones and do not extend to the subcutaneous layers.

The sites of predilection seem to be the mandible, clavicles, scapulae, extremities and ribs. Associated with rib involvemment is pleural thickening. Whipple[4] reported a case with the more infrequent site of hyperostosis in the calvarium.

In the absence of any known specific treatment, it is fortunate that all reported preceding cases have run a benign although protracted course to complete recovery. Treatment is symptomatic only. There are frequent remissions and exacerbations during the progress of the disease. However, complete recovery may be expected in three to six months.

THE RADIOACTIVE EFFECTS OF ATOMIC WEAPONS

(Continued from Page 1087)

radiation sickness. It must be recalled, however, that radiation sickness is responsible for only a small percentage of the deaths occurring after or at the time of a bomb blast. Sixty per cent of the Japanese deaths were said to be from blast, thirty per cent from burns and only ten to twenty per cent to radiation sickness. Much work is being done on blast and burns, so that it may be anticipated that if better methods of treatment for these injuries are at hand, a larger percentage will survive these injuries and the effects of radiation sickness will be more apparent.

History of Medicine In Minnesota

MEDICINE AND ITS PRACTITIONERS IN OLMSTED COUNTY PRIOR TO 1900

NORA H. GUTHREY
Rochester, Minnesota

(Continued from the October Issue)

Alexander Grant (1825-1907), of Scotch descent, was born and reared on a farm in New York. He acquired an excellent academic education, studied medicine for a time at the University of Michigan, and in 1858 was graduated from the Buffalo Medical College, of the University of Buffalo, New York. Shortly afterward he again came west and, after teaching school and practicing medicine in Wisconsin, arrived in High Forest, Olmsted County, in 1859, and there established himself as a physician. He was to remain for twenty-two years. Record indicates that he perhaps came in the hope of improving his health in Minnesota's much advertised climate, for in 1864 he was exempted from military service because of "feeble constitution," and in 1866, appointed as enrolling clerk to the state senate, he was obliged to resign because of ill health.

In the middle sixties, on the failure of Coe and Huddleston, pioneer merchants of High Forest, Dr. Grant bought their stock of goods and thereafter kept a general store as well as practiced his profession, but with less emphasis on medicine as years went by. Other physicians, O. Chase, S. V. Groesbeck, W. G. Bothwell and D. S. Fairchild, came and went between 1866 and 1873. In 1869 Dr. Grant built a two story frame building on the west side of the village green, a structure imposing for the time and place. His store and living quarters were on the ground floor; the large room above became the lodge room of the High Forest Masons. From then well into 1945, when it was razed, the building was known as the Masonic Temple. The mercantile business prospered and for a time in 1872 the doctor published a four-column advertising sheet, the *High Forest Illustrated Sensation,* describing his stock, a publication that the *Rochester Post* praised as a readable and spicy budget of business.

Of keen intellect and scholarly tastes, Dr. Grant was interested in music, literature and floriculture. He wrote and spoke well, was public-spirited, and took active interest in all matters of local enterprise and welfare. He not only organized patriotic celebrations, but was in demand throughout the county and beyond its borders as an eloquent speaker at community meetings, patriotic, political and agricultural. Although he commonly talked extemporaneously, some of his addresses were prepared; namely, certain ones on rabies and hydrophobia, the life and services of Horace Greeley, and the life of Abraham Lincoln. The *Rochester City Post* of July 13, 1867, carried in full his Fourth of July Oration of that year.

A devoted Republican, he was a member of the local central committee and regularly was a representative from the township to the party conventions of county and district. He was an organizer and the secretary of the local National Loyal League, in 1863, and an active member of the local Grant (Ulysses S.) and Wilson Club in 1872. Until 1875 he served as a petit juror of the United States District Court in St. Paul.

For some eight years he was known in medical circles, as a member of the

Olmsted County Medical Society from 1868, and of the Minnesota State Medical Society from 1872 through 1876. He was admitted to the state society together with Dr. G. W. Nichols, of Rochester, and Dr. A. W. Stinchfield, then of Dundas, at a meeting held in Rochester on June 11 and 12, 1872, during the presidency of Dr. W. W. Mayo.

Dr. Grant has been described by an early resident of High Forest who knew him well, as a short, slight, wiry man, of medium coloring and keen gray-blue eyes, who wore a small mustache and short side whiskers that terminated in a small goatee. His invariable formal costume was a suit of pepper-and-salt worsted with black velvet collar and cuffs, worn with a white collar and black tie. As time went on, certain eccentricities in his manner of living and a disregard of the niceties in his bachelor housekeeping became ingrained. In later years, when the doctor had removed to Dakota, an old friend from High Forest stopped off to see him. He was living in a dingy little general store. The combination heating and cooking stove in the center of the room was surrounded by the traditional basebox filled with sand, and the sand was covered with little heaps of coffee grounds and egg shells; the doctor told his caller that he cleaned it up periodically. In High Forest, although the citizens were amused by his peculiarities, they had affection for him and respect for his intellectual attainments.

In the summer of 1880 Dr. Grant made his first trip to Dakota Territory and in the autumn of 1881 he left permanently for the "Jim River country." After a few years in Groton, Brown County, he moved a few miles west to Bath, in the same county, where he spent the remainder of his life. He registered as a physician in Dakota on December 10, 1887, then in Bath. He died in 1907; he had never married.

George A. Gustine, a graduate physician and surgeon of some years' experience, came to Rochester, Minnesota, with his wife and children from Saratoga Springs, New York, in May, 1881, primarily to benefit his health and to visit his relatives who were established here. Liking the place and the climate, he entered medical practice, at first having his office and residence in rooms on the second floor of the Heaney Block, on Zumbro Street, over G. Stocking's Crockery and Glassware Store. Later the residence was on Grove Street. In April, 1882, Dr. Gustine returned with his family to Saratoga Springs.

Dr. Gustine was one of the seven children of Francis Gustine and Sophrinia Sexton Gustine, who for many years were respected citizens of Rochester. Mr. and Mrs. Gustine were pioneers in New England, living first in Winchester, New Hampshire, and later in Medford, Massachusetts; subsequently they were in Luzerne, New York. From Luzerne they came to Minnesota in 1879 accompanied by several of their children. A son, Levi S. Gustine, spent his life in Rochester and is survived by resident children and grandchildren. A daughter of Mr. and Mrs. Francis Gustine, who was married to A. D. Twiss, in Luzerne, came with her husband to Plainview, Wabasha County, in 1880 and to Rochester in 1881; survivors of Mr. and Mrs. Twiss in the city are a daughter, Mrs. C. M. Judd, a son, A. G. Twiss, and four grandchildren. A younger daughter, Sadie Gustine, was married in Rochester in the eighties to Nevin C. Pollock. Mr. and Mrs. Pollock, after eleven years in Evansville, Minnesota, returned to Rochester and lived there the remainder of their lives. They were survived by three children, all of Rochester: Madge (Mrs. Vernon) Gates (since deceased), Laura (Mrs. Frank C.) Jacobs, and Dr. Lee W. Pollock (1887-1947), of the staff of the Mayo Clinic.

John Haggard (1809-1875) was one of the earliest physicians in southeastern Minnesota, briefly in Olmsted County, near Rochester, in late 1856, and in that year and for some time subsequently at Fairpoint, Cherry Grove Township, Goodhue County, across the border from Concord, Dodge County. Biographical notes about him properly belong in a story of early medicine in Goodhue County; because information regarding him did not come to light until late in 1947, several years after notes on physicians of Goodhue County had been published, a brief sketch appears here. The writer is indebted to Dr. George D. Haggard, of Minneapolis, a nephew of Dr. John Haggard, for helpful response to her inquiry.

John Haggard, born on October 30, 1809, in Madison County, Kentucky, was the eldest child of David Haggard, a farmer, and Elizabeth Gentry Haggard, who came from a prominent Kentucky family. Both Mr. and Mrs. Haggard were of English extraction. They and their thirteen children were Baptists; later they all became Disciples of Christ. From Kentucky David Haggard moved with his family, in 1839, to a farm home two miles north of Peosta, Iowa, in Dubuque County.

In giving something of family history Dr. George D. Haggard wrote: "My father and mother, David and Mary Haggard, came to the Territory of Minnesota in November, 1856, stopping first near the present location of Rochester. While her husband turned back of necessity, she waited there in a tent with her three boys, with an axe at hand on the tent flap. The wolves serenaded her for three nights." When the husband returned, he was accompanied by his brother, Dr. John Haggard, who went on with the family to Fairpoint, Goodhue County; in that little community several other families, of Haggard brothers, and sisters, soon settled. There, in January, 1857, the doctor officiated at the birth of his nephew, George D. Haggard (the fourth child in a family of ten) who was born during a raging blizzard, in a log cabin that as yet lacked a roof. Mary Haggard, her son recalled, "had considerable skill in the use of herbal remedies and in the cure of the sick. She answered the calls of her neighbors on the frontier but did not consider herself a practitioner nor did she charge for her services." In those days there was much freighting from Red Wing and Pine Island, and David Haggard had the fastest team of oxen in his community. During his residence at Fairpoint he was postmaster, under President Buchanan. This family in 1862 returned to Iowa and in 1863 settled in Eau Claire, Wisconsin. In 1893 George D. Haggard was graduated in medicine from the University of Minnesota and in that year began his long practice of more than fifty-five years in Minneapolis.

About his uncle, Dr. G. D. Haggard continued:

> I do not remember my Uncle John. I do not know about his academic and professional training, but he was a man of ability and integrity. He practiced in Fairpoint and vicinity in 1856-1857 (perhaps longer), and made a number of amputations because of frozen hands and feet in that severe winter.
>
> Dr. Haggard, according to his sister, Nancy Haggard Smith, was in the Black Hawk War. Two younger brothers, Thomas and James, were in the Civil War; the father in the War of 1812; and the grandfather in the War of the Revolution.
>
> His oldest son, David, who died in 1931, spent his latest years in Algona, Iowa; one of the doctor's grandsons, John W. Haggard, son of David Haggard, is editor of a newspaper there, the Algona *Upper Des Moines*.
>
> Dr. John Haggard was married to Elizabeth Lyman on February 27, 1837, and to Irena Shaw in 1849. He died on February 18, 1875.

L. Hall was listed in the *Minnesota State Gazetteer and Business Directory* from 1880 through 1885 as a physician of High Forest, Olmsted County.

Actually the Reverend Levi Hall came to High Forest some time in 1878 as a

Methodist clergyman. In 1879 he became one of the instructors at the High Forest Seminary, a Methodist school of merit in its day.

Born in Delaware County, Ohio, on October 26, 1833, the son of a farmer, Levi Hall obtained a college education and at the age of twenty years became an ordained minister and revivalist. He was one of the original circuit riders of southern and southeastern Ohio. In 1872 he was transferred to the Minnesota Methodist Conference, and in the next years served pastorates at Austin, Minneapolis, Litchfield, Dover and High Forest.

In his circuit-riding days he often found it necessary to give aid to the sick, and the need for such treatment and his natural aptitude for healing led him to study medicine privately for many years. In 1881, then in his forty-eighth year, on taking superannuated relations in his conference (*A History of the Methodist Episcopal Church in Minneapolis and St. Paul.* By the Rev. J. Wesley Hill. 1895.), he determined to complete his medical education. He enrolled that year at the Hahnemann Medical College of Chicago, from which he received his degree of doctor of medicine in 1882; a fellow graduate in the same class was his son, Dr. Pearl M. Hall. Dr. Levi Hall returned to Minneapolis, where he had established his home in 1881, and in that city for the next thirty years he was a well-known and respected physician. He died at his home on March 22, 1911.

H. H. Herzog was the sixteenth appointee, as an assistant physician, on the staff of the Rochester State Hospital, in Rochester, Minnesota. A graduate of Rush Medical College in 1893, he came to Rochester from Minneapolis, where he had been serving as an intern at St. Mary's Hospital, and entered on his duties on December 1, 1893.

After he had been six months in Rochester, it was announced in the local press that Dr. Herzog had resigned his position to accept a similar place at the Wisconsin State Hospital for Insane at Mendota, Wisconsin. Apparently he changed his plans, since he continued for some years as a member of the hospital staff in Rochester. At a meeting of the Southern Minnesota Medical Association held at Rochester on August 1, 1895, Dr. Herzog was unanimously elected to membership; since a prerequisite to admission was membership in a local county medical society, it is assumed that he earlier had become a member of the Olmsted County Medical Society.

On March 27, 1899, Dr. Herzog resigned from the state hospital to enter private practice. Rochester newspapers commented that his home was in Racine, Wisconsin; that he would attend clinics at St. Mary's Hospital, Rochester, for a month; that he had been offered a position as lecturer at the Chicago Medical College but that he was doubtful about accepting because he was resigning to practice privately. "He is a physician of exceptional ability as well as one possessed of mental qualifications of no ordinary kind." In April, 1899, he went to Waterville, Minnesota, as locum tenens for Dr. O. M. Justice, who at one time had been an orderly at the Rochester State Hospital, with the idea of remaining in Waterville or of settling in Minneapolis.

Dr. Herzog is remembered well by citizens of Rochester. It is said that he died from angina pectoris. Probably his death occurred prior to 1906, since his name does not appear in the first edition of the directory of the American Medical Association, which was compiled in that year.

Oscar C. Heyerdale (1873——), who was born in La Crosse, Wisconsin, on May 6, 1873, has been (1950) a resident of Rochester, Minnesota, with the exception of one year, since he was eleven years old. Since 1898 he has been a physician of Minnesota, and since 1899, of Olmsted County. The twenty-fifth appointee, as an assistant physician on the staff of the Rochester State Hospital, he began his work in the institution on July 13, 1899; from August, 1912, to July, 1937, he was assistant medical superintendent.

The parents of Oscar C. Heyerdale were born in Norway. His father, Hjalmar Heyerdale, was educated as a pharmacist in Oslo, came as a young man to the United States, and settled in La Crosse, Wisconsin. There he was married to Sophie Wilhelmina Emerson. Some years later he moved with his family to Blue Earth, Minnesota, where he owned and operated a drug store. In the summer of 1884, after her husband's death, Mrs. Heyerdale with her three sons, Elmer W., Oscar C. and Frederick, came to Rochester; she died in Rochester on July 19, 1926. Of the sons, Oscar, as stated, and Frederick became permanent residents of the city; Elmer W. Heyerdale, a pharmacist, in 1947 had been for many years in Minneapolis.

Oscar C. Heyerdale obtained his preliminary education in the grade schools and the high school of Rochester. Before entering on his medical training, he was for four years a clerk and assistant pharmacist at the Weber and Heintz Drug store in the city. After one year at the medical school of the University of Minnesota, he transferred to the medical department of Northwestern University, making the change on the persuasion of his friend and classmate, Henry S. Plummer, of Racine, Minnesota, who insisted that they both go to Northwestern to take advantage of the extensive clinical material and the excellent training available there. At that time Northwestern University was one of the few institutions in the country offering a medical course of four years. The two friends were graduated in June, 1898, in a class of eighty-six students.

Immediately out of medical school Dr. Heyerdale began his initial practice in Plainview, Wabasha County, in association with the well-known pioneer physician, Dr. Nathaniel S. Tefft. He received his Minnesota license on October 11, 1898.

At the end of a year's general medical and surgical experience Dr. Heyerdale accepted his appointment to the staff of the Rochester State Hospital. A memorable assignment early in his work with the insane resulted from an abrupt change in arrangements for returning two patients to their homes abroad, one to Norway, the other to Sweden; on one day's notice the young physician started with the two insane persons on an eventful trip of seven weeks and 13,000 miles.

After twelve years as physician in charge of the wards for women at the state hospital, Dr. Heyerdale became assistant medical superintendent, succeeding Dr. Robert McE. Phelps, resigned, and in this capacity he served ably for twenty-five years. Gradually failing eyesight over a long period ultimately caused his retirement, in July, 1937, from his official position and from the scientific field in which he had won distinguished recognition as physician and humanitarian.

Throughout his professional career Dr. Heyerdale has been active in medical organizations. While in Plainview he became a member of the Wabasha County Medical Society and the Southern Minnesota Medical Association. Soon after coming to Rochester he was enrolled in the Olmsted County Medical Society (was once its president), the Minnesota Southwestern Medical Association, the Minnesota State Medical Association, the American Medical Association and the American Psychiatric Association. He is a Mason, member of the Halcyon Chapter (Worshipful Master in 1907-1908, High Priest in 1911) and of the Knights Templar. He is a vestryman of the Calvary Episcopal Church. For many years he served on the Rochester Park Board.

On June 10, 1903, Oscar C. Heyerdale was married to Gertrude Wentworth, of Rochester. Gertrude Wentworth was born in Janesville, Wisconsin, a daughter of William Cooledge Wentworth, a native of Madison County, New York, and Mary Elizabeth Moran Wentworth, a native of Jamestown, Ohio. Mr. Wentworth, at one time a railroad man, was for many years a hotel proprietor in various states of the Middle West and the West; for a few years prior to his death, in February, 1907, he lived in Spring Valley, Fillmore County. Mrs. Wentworth survived him thirty-two years and died in Rochester on September 21, 1939.

Dr. and Mrs. Heyerdale had three children, Elizabeth, who died in infancy in 1904, William Wentworth, and Louise. Dr. William Wentworth Heyerdale, a physician on the staff of the Mayo Clinic, served in World War II as a captain in the United States Army Medical Corps. He died on New Caledonia Island, in the South Pacific, on March 11, 1944; he is survived by his wife, Melanie R. Heyerdale, and three children, Melanie Anne, Sally and William S. Heyerdale. Louise Heyerdale (died, January, 1948) was married to Dr. William J. Martin (Lieutenant Commander, United States Navy, during World War II), of Louisville, Kentucky. Dr. and Mrs. Martin had three children, William J. Martin, III, Robert Heyerdale Martin, and Louise Wentworth Martin.

Mrs. Mary Hicklin, an eclectic practitioner, came to Rochester from Red Wing, Minnesota, in August, 1863. In her professional card, in the *Rochester City Post* of August 22, 1863, she announced to the public that she expected to treat all diseases with success, especially typhoid fever and dysentery; that she would treat all chronic diseases with electricity; and that she possessed one of Prof. W. P. Well's Electropathic Batteries. Her headquarters were at the Stevens House. It is assumed that her stay in Rochester was not long.

Alonzo Ward Hill (1851-1924), an early physician of Olmsted County, Minnesota, was born on December 7, 1851, near Logansport, Indiana, a son of Levi Pervine Hill and his second wife, Christena Tilden Hill. In 1856 Mr. and Mrs. Levi P. Hill came to southern Minnesota with their four children, John W., Alonzo Ward, Margaret and Sarah. In Dodge County, where they first settled, a third son, Benjamin Franklin was born. In 1860 the family established their home in Oronoco, Olmsted County. Early Oronocans have recalled that Mrs. Hill was a capable practical nurse, who gave much aid to the community in those years when physicians were few. Her father, William Tilden, practiced medicine in Ohio and in Peru, Indiana, and came to Minnesota in 1855; record has not appeared that he was a practitioner in this state.

In 1856 the Hill family had been pioneers for generations. John Hill, father of Levi P. Hill, was born in the East and came early to Indiana; his wife was Sarah Watt, who came to America with her parents, William and Unity Brown Watt, from Balygonney, North Ireland, in 1791 when she was three years old. John Hill was killed by a falling tree on his farm near Logansport, Indiana, on February 14, 1842, in his fifty-third year, and was buried in the churchyard of Spring Creek Christian Church, near Logansport; in the same plot are the graves of his daughter, Unity Melissa Hill Thompson, who died in 1860, and of his daughter-in-law (first wife of Levi P. Hill), who died in 1849. Some years after her husband's death Sarah Watt Hill joined her relatives in Oronoco, Minnesota; her grave is in the village cemetery.

Alonzo Ward Hill was educated at the village school of Oronoco and at the high school and Niles Academy in Rochester, as were other members of the family. After his graduation from the University of Michigan with the degree of doctor of medicine, in March, 1876, Dr. Hill spent a few months in Oronoco before entering into medical practice in the village of Pickwick, Winona County. From Pickwick he removed to Pleasant Grove, Olmsted County, some time in 1878; in November of that year he was married to Mattie Doris Cox, daughter of Ferdinand Cox, pioneer merchant, in 1855, of Pickwick.

In Pleasant Grove Dr. Hill operated a drug store and for eleven years practiced medicine in the village and its surrounding community. In 1882 he served as county physician for his region; on May 7, 1884, he received his Minnesota State license, No. 900 (R), under the medical practice act of the preceding year. There have been noted occasional references to his activities as a delegate to Republican county conventions.

In the late autumn of 1889 Dr. and Mrs. Hill and their only child, Mabel Ione, departed for Oregon, where they lived first in Milton and subsequently in Freewater, returning to Minnesota occasionally on business. In 1913 Dr. Hill retired from medical practice to operate his drug store. He died at Freewater on June 26, 1924. His wife, Mattie Cox Hill, died on July 31, 1944. In 1945 the survivors of Dr. and Mrs. Hill were their daughter Mabel Ione Demory, six grandchildren and six great-grandchildren.

Edgar Augustus Holmes (1852-1897) was a physician and surgeon in Olmsted County from June, 1880, to April, 1888, for a few weeks in Eyota, his boyhood home, and for eight years in Oronoco.

Born on January 20, 1852, in Chilmark, Martha's Vineyard Island, Massachusetts, he was the son of Augustus Holmes and Almira Daggett Cottle Holmes. Augustus Holmes was a sea captain on one of the old time whaling ships and made long voyages, once from New England around the Cape and north to Alaska, that were sometimes years in duration. He did not see his son until the child was two and a half years old and then, family anecdote relates, the little boy said to his mother, "Who is that strange man, Mum?"

When Edgar Holmes was a small boy, the family immigrated to the vicinity of Sheboygan, Wisconsin, where the father became a farmer and the son attended the grade schools and the high school of the town. About 1868 a second remove was made, to Eyota, Olmsted County, Minnesota, and there at the age of sixteen years Edgar Holmes began teaching country school; in 1876 he was one of the three teachers in Eyota's new school building. After nine years of pedagogy he entered on the study of medicine under the preceptorship of Dr. A. W. Stinchfield, of Eyota, who in his long career inspired and helped many young men to qualify for the medical profession. In June, 1880, Dr. Holmes was graduated from the Chicago Medical College and returned to Eyota for a few weeks before going to Oronoco, where a practice was being held for him by his undergraduate classmate and roommate at medical school, William A. Vincent *(q.v.)*. On the death of Dr. John N. Farrand, of Oronoco, by drowning on June 23, 1880, Dr. Vincent, who was employed for the summer at the state hospital for insane at Rochester (later as assistant physician), hastened to hang out his shingle at Oronoco, both to serve the people and to hold the field for Dr. Holmes.

By August, 1880, Dr. Holmes was established in Oronoco with his wife and their two small daughters; a third daughter was born in Oronoco in 1887. He had been married in 1873 to Harriet Eckles, of Eyota, one of the thirteen children of William Eckles, who originally was a skilled shoemaker, and Mary Ann Pears Eckles, early pioneer farmers in the township. Mr. and Mrs. Eckles and two small children came from Yorkshire, England, to America in 1850 by sailing vessel, a tedious voyage of twelve weeks and of many hardships. They settled first on a farm near Ripon, Wisconsin; there Harriet Eckles was born on May 4, 1854; two years later the family came by wagon to a homestead claim in Eyota Township.

In Oronoco Dr. Holmes had an arduous practice of medicine, surgery and, occasionally, dentistry, under all the difficulties of the time, in a territory that soon extended as far as Genoa and Greenwood Prairie in Olmsted County, and to Elgin and Mazeppa in Goodhue County; for a while in the late eighties he maintained an office two days a week at Mazeppa. Early in the Oronoco years his office was in James Barnett's drug store; later and for the greater period, in his own residence. In surgical emergencies his wife sometimes acted as his assistant.

Dr. Holmes has been described as a tall, well-built man weighing 213 pounds, of medium coloring, with curly brown hair and clear gray eyes, and pre-eminently as kind, sympathetic, quiet, dependable, tolerant and charitable. He won confidence and affection and, although he refused public office except as a member of the school board, it is said that the community never was more united than in the years that he was a resident of Oronoco. He neither smoked nor drank; his temper was always under control; if he said something was "cussed," it was recognized that matters were serious. He and his wife were members and generous supporters of the Presbyterian Church and for some years Mrs. Holmes was superintendent of the Sunday school. The doctor was a member of the local Masonic lodge and of other fraternal organizations. In the late eighties he was for several years co-editor of the *Pine Island Journal,* of Goodhue County.

Dr. Holmes held the esteem of the medical profession of county and state as a physician of ability and integrity. He was an active member of the Olmsted County Medical Society, the Minnesota State Medical Society (from 1882; elected third vice president in 1886) and the American Medical Association. Among his contributions to the medical literature was a paper, "Lithaemia," which he read on November 9, 1886, before the county society. It was published in the *Northwestern Lancet* of December 1, 1886; the original manuscript remains in the possession of his family. During much of his residence in Oronoco he served as county physican in Oronoco, New Haven and Farmington Townships. He was licensed in Minnesota on January 10, 1884, receiving certificate No. 679 (R).

On April, 1888, because of better professional and financial opportunity, Dr. Holmes removed to North St. Paul to enter partnership with Dr. Nathaniel S. Lane, who from 1882 to 1888 practiced medicine in Eyota; after 1894 for some years Dr. Lane was in Winona. Oronoco, in July, 1888, advertised for a good doctor at an early date; in December Dr. Charles Q. Scoboria, from Elk River, settled in the village.

After nine useful years as citizen and physician in North St. Paul Dr. Edgar A. Holmes died on August 8, 1897. He had been in failing health since 1895, when he had suffered a paralytic stroke. Mrs. Holmes lived to the venerable age of ninety years and died at her home in North St. Paul on May 23, 1944. One daughter Stelle Mabel, had died in 1889. In 1946 there survived two daughters, Myra May (Mrs. Edward) Michel, of North St. Paul, and Lulu Irene (Mrs. Roy) Allis, of Oronoco, four grandchildren and two great-grandchildren.

(To Be Continued in the December Issue)

President's Letter

ARMS AND THE MEDICAL

Post-Korean problems and the continuing war of preparedness require that the medical profession assume a heavy share of responsibility in the months and, perhaps, years ahead.

Never before, in the history of our country, has it been found necessary to pass a special law, providing for the registration, classification and induction of physicians and other allied specialist groups; but Public Law 779 is now on the statutes, by Presidential Proclamation of October 10. Minnesota's first registration, October 16, brought some 400 names on the Selective Service list, and future registrations, slated to be held before January 16, 1951, will bring in hundreds more of prospective draftees.

A chain of advisory committees, beginning with the National Advisory Committee, appointed by the President, has been established. The National Committee, in turn, appointed state advisory committees and, in Minnesota, the state advisory committee requested the Minnesota State Medical Association to establish a central committee and for each county medical society to establish a committee.

The county medical society advisory committees are to serve as liaison groups with local selective service boards, as well as to advise these boards regarding individual classifications and the policies established by the National Advisory Committee.

In outline, this chain of advisory groups will operate in much the same manner as Procurement and Assignment procedures of World War II.

If the system is to prove efficient and in the best interests of each community, the state as a whole, and the profession, it will require the co-operation of every physician.

Questionnaires have been mailed to registering physicians and these are being returned to the State Office for referral to advisory committees. Facts about the physician and the community he serves will have a bearing on his classification. Complete information will aid these committees in giving the greatest assistance to the military services without impairing the health of the civilian populace.

J. J. Elias.

President, Minnesota State Medical Association

REGISTRATION AND INDUCTION OF PHYSICIANS

PHYSICIANS as well as laymen can be excused for their lack of enthusiasm for exchanging their civilian life for the military. Those who served during the war and had their normal peaceful lives disrupted have the feeling they have done their duty and are loath to don the military after a mere five years of civilian re-establishment. Those who have never served having also been loath to volunteer a program had to be developed which would be as fair an apportionment of a distasteful job as was possible. Those who have never served are to be called first and those in the reserve last—as far as is reasonably possible. The present plan seems as equitable as possible although there are bound to be inequalities develop here and there.

On October 16 physicians (and dentists) who had obtained their medical (and dental) education through ASTP or V-12 or who were deferred for educational reasons and who had had less than twenty-one months of service were required to register.

According to newspaper reports 113 physicians registered in Hennepin County, forty-one in Ramsey, ninety-seven in Olmsted (Rochester), nine in Cook (Duluth) and one in Blue Earth County (Mankato) on this date.

The World War II system of procurement and assignment of physicians has been revived, and each state will have its committee composed of a physician, dentist and representative of the state public health department (the physician to be chairman) to work with the National Advisory Committee in the selection of doctors, dentists and allied specialists in Washington.

Those who received their training at the expense of the government and who have served less than ninety days are First Priority. Those who have served more than ninety days and less than twenty-one months are classed as Second Priority. Although both First and Second Priority groups registered, the First Priority will be processed first. Registration dates for all other physicians under fifty and not in military reserves will be sometime before January 16, 1951, and will constitute a future priority.

Indications are that inductions will not be made in large numbers until late in December, and registrants will be allowed twenty-one days to settle personal affairs before being inducted.

Fewer World War II reserves than anticipated will be called into active duty within the next few months and these for only three or four months in most cases rather than for the full twenty-one months. World War II reserves will be utilized only until non-veteran replacements can be mustered into service and it is said that an effort will be made to return veteran reservists to civilian life as fast as possible. Exceptions to this relaxed policy will be certain senior officer specialists and senior command and staff officers whom it will be difficult to replace.

The army is undertaking to offer a reserve commission to every registrant at the time he takes his physical examination and before his induction. Further, physicians can volunteer for any military service before they are inducted and receive the $100 monthly bonus pay which goes with volunteers.

This seems to be the present status as to Uncle Sam's requirements of the medical profession. What the future weekly bulletins will contain or what the future will require is unpredictable. One thing is certain. We must arm for defense on such a scale that none will dare attack us. If the enemies of free people eventually see the futility of living in a world armed to the teeth, we shall all be able to revert back to a peaceful footing.

GOOD DOCTORS AND BAD MEDICINE

IT should be unnecessary to state that the most important function of the American Medical Association is the preservation of the nation's health. The Association endeavors to carry out this objective in many ways. Probably the most valuable of these is protection of the public against exploitation of remedies that are worthless or of doubtful value. This function is carried on by the Council on Pharmacy and Chemistry which carefully investigates the therapeutic value of all drug products submitted to them. If a therapeutic product is found to meet the claims made for it by the producer, it receives the Council's seal of approval and the drug is so advertised in official medical journals. This would seem to be a simple and practical way to protect the public by guiding the physician in selecting drugs of proven merit. One might expect that the medical profession would be unanimous in supporting the AMA in this most important activity. Sad to relate, however, this is not the case.

Although most state medical journals advertise only those drugs which have been approved by the Council of the AMA, there are several state and county medical associations which do not. In fact, in some of these medical journals a large part of their advertising columns is taken up with unapproved remedies. The reason for this is obvious. Instead of balancing the budget of state and county medical societies by adjusting membership dues, the officers stoop to accept income from questionable advertising in their medical journals.

Advertising of pharmaceutical products that are not accepted by the AMA is not confined to state and county medical journals. The official publications of several national societies also contain many pages of sub-standard advertising. In recent numbers of the official journal of a well-known society, more than 60 per cent of the advertisements were unapproved by the AMA. Even more reprehensible is the fact that this same medical organization permits the display of these doubtful remedies in the commercial exhibits at its annual meetings. The contrast between information offered by excellent scientific articles in some of these journals and misinformation contained in the advertising pages should arouse the callous editorial conscience.

There are also the so-called "throw-away" medical journals. These periodicals are printed by commercial publishers who distribute them gratis to members of the medical profession. They depend entirely upon their advertising columns for income. It is no wonder that they are lucrative since their pages are filled with ads of remedies unapproved by the AMA as well as some that are so shady that even lay newspapers might hesitate to accept them. Members of the medical profession are lured to read these journals by means of handy abstracts of recent medical papers dished up in attractive form or by articles on economic problems of medical practice. One might expect the intelligent physician reader would disregard doubtful advertisements. The astute publishers know, however, that the medical reader fails to distinguish the approved products from the unapproved and falls for catchy advertisements just like his lay brother.

One of the phenomenal developments of our time is the enormous number of new drugs and therapeutic agents that are constantly being offered to the physician by drug manufacturers and by research laboratories. Some of these products have the therapeutic merit claimed for them by the producers; others do not. Some are definitely harmful and these should be so labeled before they are put on the market. The need for an impartial and disinterested authority to examine new drugs and verify the claims made for them by the manufacturers is self-evident. The AMA generously assumed this function at no little cost to itself by creating the Council on Pharmacy and Chemistry in 1905. The Council consists of seventeen outstanding scientists and a full-time secretary. It has an extensive chemical laboratory available in AMA headquarters. In order to expedite their investigations and render their decisions more accurate, the Council has been aided in recent years by a representative group of specialists called the Therapeutic Trials Committee. The members of the Council work without remuneration and have faithfully carried out their responsibilities over the years at a great sacrifice of time and effort on their part.

The average physician does not realize how much the Council has done to raise the standard of American medicine to its present high level. It is constantly offering practical as well as scientific information concerning every new pharmaceutical product that has therapeutic value. It has been responsible for many special articles, giving a summary of wide clinical experience. It has embodied this mass of information in several books such as "New and Non-official Remedies" and others. The Council also has encouraged research for new and better therapeutic products. In fact, it has been the stimulant for the outstanding research carried on in many scientific laboratories including those of the American Pharmaceutical Industry. It may well be said that the work of the Council alone would justify the existence of the American Medical Association.

Let us see first if there is any logical reason why approval of drugs by the Council on Pharmacy and Chemistry should be disregarded. Is it true, as has been claimed, that legitimate products have been turned down? Is it true that the delay sometimes caused by thorough examination of a drug is unfair to its manufacturer? Is it necessary to depend on the Council for investigation in order to determine the value of a drug? Would not the experience of a practitioner who employed the drug be of equal value? These are some of the critical questions put by commercially minded medical organizations and by manufacturers of unapproved products. Although formerly there was some delay on the part of the Council in completing its investigation of a product, that has been corrected. Prolonged delays almost invariably are due to failure on the part of the manufacturer to submit sufficient data to substantiate their claims or that are necessary to carry on investigation. A product which is submitted with necessary information can be accepted by the Council within a period of six to ten weeks. In fact, if necessary, the Council can complete consideration of a drug within two or three weeks. The claim that the limited personal experience of a practitioner, without laboratory control, is just as good as the thorough clinical and laboratory investigation made by the Council, aided by a group of experts in the field involved, is of course ridiculous.

Many of the larger and well-established producers of pharmaceutical products co-operate with the Council and abide by its rules in obtaining acceptance of their new preparations. In fact the American drug industry deserves great credit for the scientific methods employed in the manufacture of their products and for the high standards of research conducted in their laboratories. Unfortunately, however, there are many members of the drug industry who do not abide by the Council's rules of acceptance. In fact, the group of drug manufacturers who flagrantly disregard the Council's efforts are increasing in number and in influence. Aided by officers of medical societies who place profit above principle and by throw-away medical journals, they find that they are able to bootleg their wares successfully. Unless their efforts are blocked, they threaten to undermine the work of the Council.

There are many loyal members of the AMA who recognize the need and value of the Council and yet they sabotage it by prescribing unapproved drugs. There are physicians with outstanding professional reputations who allow their names to appear on editorial boards of medical journals which are loaded with advertisements of unapproved drugs. Other outstanding physicians allow their names to be listed as officers of medical associations that sponsor such journals. These men are used as fronts, and in that capacity they indirectly lend endorsement to the character of the journal including the advertising pages.

The medical profession can limit traffic in uncertified drugs by refusing to prescribe any drug that does not have the seal of approval. The officers of transgressing medical associations, the editors, the scientific contributors, and even the subscribers to mercenary medical journals should scrutinize the advertising columns, and if unapproved drugs are displayed, they should register their objections. A wide-spread movement of that kind would soon correct the misleading and mercenary advertising now published in many medical journals. The public would approve of such action and it would be a tremendous boost to our public relations. Such action also would be of great aid in starting a sadly needed house cleaning in the advertising columns of the lay press and in the radio. These lay transgressors can point in defense to similar conditions now existing in the advertising pages of medical journals. The medical profession must proceed immediately to clean its own house. It can do so by two ways: by prescribing only those pharmaceutical products that are certified by the Council and by forbidding advertisement of unapproved drugs in its medical journals.

William F. Braasch, M.D.

LUETIC AORTITIS

Attention has been called of late to another sign which is apparently quite diagnostic of luetic aortitis. Jackman and Lubert were the first to call attention to the significance of a linear appearing calcification in the ascending aorta in the x-ray film. It has been shown by these authors,[1,2] and others[3] that a large percentage of individuals showing this type and location of calcification have luetic aortitis.

It is known that lues has a predilection for the root of the aorta. Whether the calcification in this area represents a healing of the luetic process in this area or is a sequel of an arteriosclerotic process in this area initiated by syphilis is not known and is perhaps not important. The important point in differentiation is that calcification accompanying simple arteriosclerosis appears blotchy in the x-ray film and is located beyond the root of the aorta.

While this linear appearing calcification in the root of the aorta is practically diagnostic of late syphilitic aortitis, its absence is not significant. In the presence of this x-ray shadow the diagnosis of syphilitic aortitis can be accepted until proven otherwise.

LESS SYPHILIS

THE report of the Committee on Syphilis and Social Disease of the Minnesota State Medical Association submitted to the House of Delegates at Duluth in June merits emphasis not only because it indicates a marked reduction in the incidence of syphilis in Minnesota in recent years but because it emphasizes one very important point in the medical care of syphilitics. All patients treated for syphilis should have a spinal Wassermann test performed during or at the conclusion of treatment. A spinal examination becomes a "must" for any patient whose blood Wasserman persists as positive after an adequate course of treatment or over a period of five years. This is, of course, the only way asymptomatic neurosyphilis can be diagnosed, and the importance of making the diagnosis lies in the fact that asymptomatic neurosyphilis can in many instances be successfully treated with penicillin. Such successful treatment obviates the necessity in these instances of long periods of hospitalization for tabes and paresis at a later date and constitutes a great saving financially for the state, to say nothing of a much better outcome for the patient.

The reduction in the incidence of syphilis in Minnesota during the past thirty years—the incumbency of Dr. H. G. Irvine as director of the Division of Venereal Diseases of the State Department of Health—is almost unbelievable and is a tribute to Dr. Irvine and his associates. In 1925 some 4,300 cases of syphilis were reported in the state. Since then the number reported yearly has shown a steady decline, except for an occasional increase, until last year when only sixty-nine cases of early syphilis were reported. Since 1940 the average number of new cases reported yearly has been 301, the higher than average number reported in 1946 being doubtless due to the return of the soldiers from the war.

On the other hand not enough spinal Wassermann tests are being performed. In 1948 a total of 488 latent or late syphilis cases was reported but only 202 had any record of a spinal fluid test. In 1949 out of a total of 422 such cases only 160 had spinal tests.

While there were thirty-one cases of congenital syphilis reported in 1949, only one of these was a child born in 1949, thirty having been born previous to that year. Only one congenital syphilitic out of 73,627 live births in 1949 is something to be proud of.

So satisfactory is the penicillin treatment of the disease in all its phases that the state is willing to provide this antibiotic for those unable to afford the cost. Office treatment to the extent of 3,000,000 to 6,000,000 units over a period of fifteen days is highly satisfactory and fully as effective as larger doses. The early treatment of syphilis is preventive in nature, and the assumption of the cost of medication by the state when the individual is unable to afford it is justified from a realistic standpoint.

SALINE SOLUTION IN TREATMENT OF BURN SHOCK

The Surgery Study Section of the National Institutes of Health has recommended to the Surgeon General of the Public Health Service that the use of oral saline solutions be adopted as standard procedure in the treatment of shock due to burns and other injuries in the event of large-scale civilian catastrophe.

The recommendation followed action taken at the January, 1950, meeting of the Surgery Study Section, when such treatment was approved in principle. Dr. Carl A. Moyer, a member of the Study Section, was designated at that time to prepare a memorandum suitable for submission to Dr. Norvin A. Kiefer, Director, Health Resources Division (now Health Resources Office), National Security Resources Board.

EDITOR'S NOTE: The above article calls attention to a simple adjunct in the treatment of shock due to burns and other injuries which has been found to be of value. It is, therefore, being published for the information of the profession of Minnesota.

Dr. Moyer's memorandum, which was submitted to Dr. Kiefer on February 15, 1950, reads as follows:

"Since the publication of the experimental work of Dr. Rosenthal, Dr. Joller, et al, orally administered salt solutions have been employed in the treatment of burns at the University of Michigan Hospital, Ann Arbor, Michigan; at the Wayne County General Hospital, Eloise, Michigan; and at Parkland Hospital, Dallas, Texas. Personal clinical experience, in the above-named hospitals, has convinced me that the orally administered salt solutions are valuable adjunctive agents in the treatment of shock incident to burns, fractures, peritonitis, and acute anaphylactoid reactions. Certain factors are important in governing the effectiveness of the oral administration of salt solutions. They are as follows:

"1. The composition of the salt solution: The most palatable salt solution is made by dissolving 3 to 4 grams of sodium chloride and 2 to 3 grams of sodium citrate in each liter of water. If sodium citrate is not available, ordinary baking soda may be substituted for it.

"2. The concentration of salt should not be in excess of 140 milliequivalents of sodium per liter. If the concentration is above this, vomiting and diarrhea become important complicating factors.

"3. Whenever profound peripheral circulatory collapse is present, the intravenous route of administration must be used until peripheral blood flow has been reestablished. The salt solutions that we have found most satisfactory for this purpose are Hartmann's solution (Lactate-Ringer's solution) or plasma. In addition to the salt solution or plasma intravenously, whole blood is given concurrently whenever peripheral circulatory collapse exists. This materially implements the effectiveness of salt solutions.

"The slightly hypotonic salt solution is the only drinking fluid permitted the injured individual until the edema of the injured parts begins to subside. Certain exceptions to this rule have to be made during the hot weather of summer when it is sometimes necessary to permit the partaking of some non-salty water.

"A much as 10 liters of the hypotonic salt solution have been drunk in the twenty-four-hour period by adults who have been severely burned. Since salt solution has been substituted for water, as a drinkable fluid, no burned person who has lived for longer than three hours after being admitted to the hospital has suffered from anuria. The 'early toxemia phase' of the burns has also failed to appear and the osmotic concentration of the plasma electrolytes has been well maintained.

"We feel that much more clinical observation and actual experimental work should be undertaken regarding the effectiveness of the basic principles of the supportive therapy of burns that have been so beautifully demonstrated by Dr. Rosenthal. It is obvious that the adoption of a more active program of investigation into the relative effectiveness of simple measures to combat shock would be of extreme importance to the Armed Forces and to the civilian population in the event of another war."

Because of the sharpened national emergency that developed during the summer of 1950, the Surgery Study Section, in approving Dr. Moyer's memorandum at its meeting on September 16, changed the last paragraph to read:

"While further clinical research concerning the effectiveness of oral salt solution in the treatment of burns and other injuries is certainly in order, there is already sufficient evidence to suggest that this form of treatment should be used in any large-scale disaster involving the civilian population."

The Surgery Study Section letter to the Surgeon General, dated September 16, 1950, reads as follows:

"It is my understanding that one of the functions of the Study Sections is to offer advice to the Surgeon General in fields of medicine lying within the special competence of the Study Section members. At the January, 1950, meeting of the Surgery Study Section, there was considerable discussion concerning the use of oral saline solutions in the treatment of burns and other serious injuries. It was the consensus of the Section at that time that, on the basis of the animal work which had been done by Dr. Rosenthal of the National Institutes of Health, and the clinical work which had been done by Dr. Carl A. Moyer, by the undersigned, and by others, the efficacy of such treatment had been definitely demonstrated and that, while there is need to stimulate additional research in this field, our present knowledge is sound enough so that action can be taken on this basis. Dr. Moyer was designated to draft a short memorandum expressing our point of view on this subject. Such a memorandum was prepared and furnished to Dr. Norvin C. Kiefer, Director, Health Resources Division, National Security Resources Board, on February 15, 1950. A copy of Dr. Moyer's memorandum is attached.

"In view of the more acute national emergency that has developed since Dr. Moyer wrote this memorandum, the Study Section, at its meeting on September 16, 1950, voted to recommend that the principles of treatment outlined in his memorandum be adopted for widespread use in any large-scale disaster involving the civilian population. Because of the present emergency situation, we have modified the last paragraph of Dr. Moyer's memorandum to read, 'While further clinical research concerning the effectiveness of oral salt solution in the treatment of burns and other injuries is certainly in order, there is already sufficient evidence to suggest that this form of treatment should be used in any large-scale disaster involving the civilian population.'

"You are at liberty to transmit this recommendation of the Surgery Study Section to the National Security Resources Board or to other proper agencies, and, if you see fit, to publish it. We feel strongly that it is important for the medical profession of the country and for those planning for the handling of potential disasters to be informed of the value of this simple and easily carried out form of treatment."

The letter was signed by Frederick A. Coller, M.D., University of Michigan, Chairman of the Surgery Study Section.

MEDICAL ECONOMICS

Edited by the Committee on Medical Economics
of the
Minnesota State Medical Association
George Earl, M.D., Chairman

NEWSPAPER COMPLAINS OF TOO MANY ZEROS

Using its familiar method of sly kidding with a serious undertone, the Wall Street *Journal* recently found that the "billion dollar era" makes it rather uncomfortable. The *Journal,* and probably most Americans, finds that figures of the national debt and federal spending are a little difficult to understand, and too many zeros can have ominous implications. The paper says:

> "Frankly, we've never felt at home in the billion dollar era. A dozen ciphers added onto a digit or combination of digits blurs our economic comprehension.
>
> "We can easily grasp five cents for a pack of chewing gum or one dollar for a haircut or even seventy-five dollars for a new suit. But 40,000,000,000 or 45,000,000,000 as a measurement of dollars brings on a sort of myopic miscomprehension that leaves us not quite sure what it means."

The Explanation—Simple?

The *Journal* had hopes of being able to count the costs of government after the second world war, but now has to try to see the figures of spending in a proportionate light—giving each second an amount to spend. The result is:

> "After a World War II spending spree that left endless zeros whirling wildly through our head, we hoped things might settle down where we could see and count the cost of government. But that hasn't happened and now the cost is on the rise again.
>
> "To try to bring the spending down to our size we've taken this fiscal year's prospective spending, some $40,000,000,000 to $45,000,000,000 and translated it into so much per second—through the year. That comes out to a minimum $1,720. What that means is that while we smoke one cigarette $228,000 disappears. And in the time it takes us to commute from home to office each morning $6,000,000 is gone."

There's a Moral

In the time it takes to smoke away $6,000,000, the average taxpayer stops to realize that his money is going altogether too swiftly. The more the government spends, the more it has to spend, and the more control it wields. The *Journal* wisely advises that tax money should be more carefully spent, and not squandered on schemes which are unnecessary to the citizens' good:

> "We know that wars are costly. But a lot of those dollars have nothing to do with war or defense. They go to subsidize housing and buy 'surplus' potatoes and dried eggs and a lot of things we could do without."

The moral to the whole story seems to be that if American voters choose the correct members of Congress, less lavish spending will begin to be evident in the Eighty-second Congress beginning in January.

INDUSTRIALISTS EXPLAIN DEMAND FOR PENSIONS

The key factor behind the demand for pensions was explained recently by a speaker before the National Association of Cost Accountants. Percival F. Brundage, of Price Waterhouse & Co., sounded the warning that, "Debasement of the dollar is a key factor behind the demand for pensions. This is so," he said, "because inflation discourages personal savings by reducing their value as time goes by."

Adding his note of warning that continued decreased value of the dollar will make savings for old age smaller in purchasing power, Robert C. Tyson, comptroller for United States Steel Corp., said:

> "Thus, if there is a continuing debasement of the money, with resulting price and wage inflation, then the dollar amounts to the pension based upon the level of wages of the last ten years of service will be greater than were provided for during the earlier years of service at lower levels of dollar wages. The dollars set aside during these earlier periods therefore may prove insufficient and have to be made up at higher costs than were previously calculated."

Mr. Tyson's remarks had been limited to private pension plans, but he then stated, "Government Social Security plans are similarly complicated, but the Government can always manipulate the currency."

Those falling under the new social security groups, will wonder if the government will use its power to manipulate the currency once again, thus exercising more control over more people than ever before in peace time. Mr. Tyson remarks:

> "Can you think of a handier and more popular device for power-hungry people to employ in obtaining support than promises to take good care of people when they get old—that is, later on? The 'later on' is very important to the promiser; he gets the popularity he seeks today. As for paying up tomorrow—well, tomorrow is another day, and if necessary the currency can be debased. It has been in other times and places. In this country it already has been debased by nearly one-half since social security was first promised to numerous voters."

AMA RISES AGAIN TO ANSWER EWING

Oscar R. Ewing, in his own *little* way, has again reverted to smear tactics in a new vicious attack on the American Medical association. By injecting the racial issue into his blows, Ewing belittled himself more than usual by accusing medical schools of practicing discrimination against Jews. The American Medical association replied with the following news release:

> "The American Medical association in a blistering indictment of Federal Security Administrator Oscar Ewing, which stated that he had twice been given a vote of 'no confidence' in Congress, today characterized him as a 'disappointed, embittered bureaucrat, who should be removed from office before he does further harm to the country.'
>
> "Dr. George F. Lull, Chicago, general manager of the A.M.A., who issued the statement, declared:
>
> 'Mr. Ewing, in his speech . . . before the American Jewish Congress, descended to the depths of political demagoguery when he falsely implied that the American Medical Association was practicing discrimination against Jews . . . The two Houses of Congress, in successive years, have given Mr. Ewing a decisive vote of no confidence, by rejecting his attempts to gain Cabinet stature and control over the medical profession through the creation of a Department of Health, Education and Security.
>
> 'President Truman should finish the job and dismiss Mr. Ewing from the public service before he does further harm to the country.'"

DOCTORS GET SMALL FRACTION OF COUNTRY'S MONEY

People who are inclined to think that American doctors make money hand over fist should realize that much of the doctor's time is given gratis and that *twice* as much is spent for other health services as for physicians' fees.

According to a government survey, made public recently, only about one-third of the money spent for health purposes goes to physicians in payment for their services.

Citing the figures in the Commerce department's "Survey of Current Business," The Bulletin of the Academy of Medicine of Cleveland says:

> "During the 12 months (1949) physicians received $2,267,000,000. During the same 12 months Americans were spending $1,391,000,000 on drugs, $105,000,000 on private nurses, $416,000,000 on ophthalmic products and orthopedic appliances and $1,631,000,000 on private hospitals. (Incidentally, if non-private hospitals were included—U. S., state and local—the hospital cost figure would be several times as high, with a subsequently greater difference between payments to physicians and payments for other health services.)
>
> "Several other comparisons are interesting. For instance, $395,000,000 went for such burial items as cemeteries, crematories, monuments and tombstones. This figure, according to the survey, just about equals the 'net amount' spent for accident and health insurance. It is almost four times as great as expenditures for private nurses, and it is found to total almost half the amount paid to dentists . . ."

AMERICAN DOCTOR STUDIES BRITISH HEALTH SERVICE

An American doctor, recently returned from Great Britain, made a comparison of medical care and costs under national health service in England, and medical care and costs under the American medical system.

While admitting that the American system of medicine, good though it is, has many faults, Dorothy V. Whipple, M.D., quoted in *The Survey*, remarks, "Frankly, as an American doctor, I was shocked at the quality of medical care given by the English urban general practitioners."

Reporting on differences between the British and American systems, Dr. Whipple says:

> "In the United States, distinctions between general practitioner and specialist are not sharp. Often a patient may not be quite sure whether or not his

doctor is a specialist." (This would never happen in England.)

Dr. Whipple also studied the fee system and how it works:

> "The general practitioner receives a capitation fee—that is a flat sum per year for each name on his registry, regardless of how many times the doctor sees the patient. Specialists are paid salaries varying with their skill.
>
> "To an American observer the disadvantages of the old British system seem more firmly established under the new scheme, which reinforces the wall between general practitioner and specialist."

More Patients, Poorer Care

With the advent of National Health Service, Dr. Whipple states, most doctors found they had more work to do. "Even though a doctor served exactly the same area and the same families as before, he had more calls as soon as no direct payment was required. Part of the increased load represented persons who had put off medical care because they could not pay the bill. Some of the increased load was foolishness—people who wanted what they could get because it was 'free.'"

The kind of medical care received is described by Dr. Whipple:

> "But what of the care these people receive? The general practitioner's income depends not on the number he treats but the number registered with him. The law says he may not have more than 4,000 on his list. Obviously no doctor can give much care to each of 4,000 men, women and children, even if only half of them actually require his services in any one year.

Calls GP a "Clearing House"

> "The more patients the general physician has, the greater is his tendency to refer cases to the hospital and the specialist. As a result, he becomes increasingly a clearing house, less and less a real practitioner of the healing art. He is so busy he has little time for preventive medical service. All too often he prescribes the customary bottle of sedative and allows the patient to go along to see whether anything serious develops."

DECREASE IN TUBERCULOSIS

In 1937, Wade H. Frost concluded that the point had been reached in the United States where there is a gradual downward trend in the incidence of tuberculosis, and that, barring major upsets in civilization, the eventual eradication of the disease can be expected. The continued decline in the annual number of deaths from tuberculosis during the past twelve years, in spite of the adverse conditions caused by a great war, is ground for confidence in the accuracy of Frost's conclusion. A. C. CHRISTIE, M.D., *Pub. Health Reports,* June 2, 1950.

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

230 Lowry Medical Arts Bldg.
Saint Paul 2, Minnesota

J. F. DuBois, M.D., Secretary

St. Paul Woman Sentenced to Jail Term for Criminal Abortion

Re State of Minnesota vs. Helen A. Heck.

On October 13, 1950, Helen A. Heck, forty-three years of age, 809 Iglehart Ave., Saint Paul, Minnesota, was sentenced by the Hon. Gustavus Loevinger, Judge of the District Court of Ramsey County, Minnesota, to a term of not to exceed eight years in the Women's Reformatory at Shakopee. The defendant Heck had previously entered a plea of guilty on September 19, 1950, to an information charging her with the crime of abortion and to having a prior conviction in 1947, also for the crime of abortion. Following a statement by the attorney for the defendant, and legal counsel for the Minnesota State Board of Medical Examiners, Judge Loevinger ordered the case continued to April 6, 1951, at 2:00 p.m., the defendant, however, to remain in the custody of the Sheriff of Ramsey County. This means that the defendant will have to serve the first six months of her sentence in the Ramsey County Jail and the Court will then determine whether or not the balance of the sentence should be stayed and the defendant placed on probation. Judge Loevinger cautioned the defendant that probation was hardly indicated by her past record. The Court also stated that the defendant "undertakes to practice medicine and surgery without having the necessary qualifications."

The defendant Heck, who has no medical training of any kind, was arrested by Saint Paul police officers on September 10 ,1950, following the admission of a twenty-two-year-old Minneapolis divorcee to Minneapolis General Hospital suffering from the after effects of a criminal abortion. The police also discovered another patient, a twenty-one-year-old unmarried Saint Paul girl, in the apartment of the defendant Heck upon whom the defendant had attempted an abortion. The investigation disclosed that the defendant received $265 for her services in the Minneapolis case, and $425 for her services in the Saint Paul case. Police also seized one speculum, 14 rubber catheters and numerous medicinal preparations in the apartment of the defendant. On September 18, 1950, a complaint was filed against the defendant in the Municipal Court of Saint Paul, charging the defendant with the crime of abortion in the Minneapolis case. On September 19, the defendant was arraigned in the Municipal Court, waived a preliminary examination, and was held to the District Court. On the same date, the defendant was arraigned in the District Court on an information charging her with the crime of abortion, and to that information she entered a plea of guilty. The Court then continued the matter to October 13, for sentence as outlined above.

The records in the office of the Clerk of the District Court of Ramsey County disclose that the defendant Heck has a prior conviction for the crime of abortion. On August 21, 1947, the defendant, together with one Assunda Willner entered a plea of guilty in the District Court of Ramsey County, to an information charging both with the crime of abortion. For that offense Judge Parks sentenced the defendant to a term of not to exceed four years in the Women's Reformatory at Shakopee but stayed the sentence after the defendant served sixty days in the Ramsey County Jail.

Minnesota Department of Health

METHEMOGLOBINEMIA IN INFANTS

During 1947, 1948, and 1949, 146 cases of methemoglobinemia in infants due to nitrates in well water were reported. This included fourteen deaths. For a period of ten months no cases were reported but during the past five months fourteen cases have been reported, with two deaths. As physicians became familiar with this condition during the study carried out by the Minnesota Department of Health, parents with newborn infants were warned to use only approved municipal water supplies or safe private water supplies. In recent months, however, physicians have apparently neglected to inform parents of the danger of using questionable well water in infant formulas, especially in southwestern Minnesota.

A brief résumé of the study of methemoglobinemia in infants due to nitrates in well water is given to remind physicians that this disease must be kept in mind. Ninety per cent of the infants were under two months of age and about 8 per cent were between two and five months old. The youngest infant was seven days old and the oldest was five months old. More than half of the infants developed symptoms in one to three weeks after being on a formula requiring considerable water as a diluent. Fifteen per cent developed symptoms in less than seven days, the shortest period being one day. No breast-fed infant developed cyanosis. Evaporated milk mixtures were responsible for 40 per cent of the cases, powdered milk formulas for 35 per cent and diluted cow's milk for 25 per cent. The characteristic symptom is a grayish blue or brownish blue cyanosis accompanied frequently by listlessness or lethargy, diarrhea, or fussiness. Most of the private water supplies involved were shallow dug or bored wells within 50 feet of a source of pollution and contained from 25 to 50 parts per million of nitrate nitrogen, the average being from 50 to 75 ppm.

A presumptive diagnosis may be made if on removal of venous blood for hemoglobin determination the blood is chocolate colored and if there are more than 10 to 20 parts per million of nitrate nitrogen in the water used in the formula. Such a diagnosis is justified if there is spontaneous disappearance of the cyanosis in 24 to 48 hours on changing the water in the formula to an approved water supply and the nitrate nitrogen content of the water used in the formula exceeds 10 to 20 parts per million. In either case the history and physical findings should be typical. An absolute diagnosis is made by demonstrating a definite methemoglobin live on spectroscopic examination or by the chemical analytic method of Evelyn and Malloy.

In the differential diagnosis certain serious conditions must be ruled out, including congenital heart disease, pneumonia, atelectasis, pneumothorax, diaphragmatic hernia, congenital pulmonary, and tracheal malformations, and "thymic syndrome." It is well to remember Ferrant's observation, that there is a striking difference between the cyanosis and the alarming condition of the infant on the one hand, and the normal pulse and respiration and lack of physical findings on the other.

In mild cases, treatment consists of changing the water used in the formula to an approved municipal supply. Many physicians use oxygen but there is considerable doubt as to its value in this condition. Ascorbic acid has been used successfully. In severe cases, one per cent methylene blue solution, one to two mg. per kg. intravenously, may be life saving.

It is requested that physicians notify the Minnesota Department of Health, University Campus, when such infants are seen, and that samples of well water be mailed to the department for nitrate analysis. A copy of the reprint of the article on methemoglobinemia which appeared in the August, 1950, issue of MINNESOTA MEDICINE is available on request.

BIRTH AND STILLBIRTH CERTIFICATES

Revised certificates of death, live birth, and stillbirth have been developed and were first used in Minnesota beginning January 1, 1950. A discussion of these new forms of vital records by Casady and Brower appeared in the December, 1949, issue of MINNESOTA MEDICINE. The importance of exactness in reporting was pointed out and emphasis was given to the necessity for accurate data on birth weight, prematurity, and congenital malformations. Since prematurity was the ninth leading cause of death and congenital malformations in tenth place in Minnesota in 1949 such information is needed in the development of programs related to the care and survival of premature infants as well of problems involved in congenital malformations.

A preliminary review of 20,000 birth certificates indicates that there is some confusion as to the definitions of live birth, stillbirth, and prematurity. The following definitions should clarify the situation. The international definition of a *live birth* is the complete expulsion or extraction from its mother of a product of conception, irrespective of the duration of pregnancy, which after such separation, breathes or shows any evidence of life such as beating of the heart, pulsation of the umbilical cord, or definite movements of voluntary muscles, whether or not the umbilical cord has been cut or the placenta is attached.

Full term pregnancy varies from 220 to 330 days, with an average of 270 days. This is the equivalent of nine calendar months of thirty days each or approximately ten lunar months of twenty-eight days, computed on the basis of Naegele's rule, from the date of onset of the last menstrual period to delivery. A full-term pregnancy is, therefore, not thirty-six weeks but is actually forty weeks of gestation.

A *stillbirth* is a delivery of a fetus showing no evidence of life after complete birth (no action of heart, breathing, or movement of voluntary muscle), after

Minneapolis Surgical Society

Meeting of January 5, 1950

The President, Ernest R. Anderson, M.D., in the Chair

ACUTE CONDITIONS OF THE ABDOMEN

L. A. STELTER, M.D.
Minneapolis, Minnesota

The reason for the common pitfalls in the diagnosis of acute abdominal conditions is that we think of the multitude of possibilities rather than the few outstanding conditions which confront us in everyday surgery.

To elaborate on all the possible catastrophes of an abdomen only adds to confusion with wasted time and words. In order to make our job more practical and efficacious, let us have a definite plan of attack by combining our anatomic location of disease, clinical, and laboratory findings in such a way that the diagnosis may be reached more easily and then treat the patient accordingly.

First, for simplicity, let us divide the abdomen in two planes: the upper abdomen, that part lying in the plane above a line drawn transversely through the umbilicus, and the lower abdomen, that part lying beneath this same line.

Let us consider the most common conditions which may occur in these planes. Next we shall combine our history, present complaints (male or female), physical findings, laboratory and x-ray findings in such a way that a conclusion may be reached.

Those conditions occurring in the upper abdomen are:

1. *Acute Cholecystitis.*—It has been said that certain people develop certain diseases and this seems to hold here; the gall-bladder type are fair, fat, and forty, though occasionally a very thin patient under forty years of age may develop the most severe gall-bladder disease. The chief complaints of the patient are pain, food distress, food dyscrasia, belching, and bloating. The four foods most offensive are fried and fatty foods, raw apples, cucumbers, and cabbage. Thorek calls such people the 7 F's—female, fair, fat, forty, flatulent, flabby, and fertile.

The pain may be intense and constant or intermittent and colicky. Colicky pain indicates an obstructive lesion or the passage of a stone. The pain is located in the right upper quadrant and radiates along the costal nerves to the back and scapular region. Occasionally it may be referred along the splanchnic nerves which supply the stomach and must not be confused with ulcer or carcinoma of the stomach. Gall-bladder pain does not refer to the shoulder. Shoulder pain is due to phrenic nerve irritation and is due to a different mechanism.

The temperature, pulse and respiration are elevated. The temperature of the acute gall bladder rises to 101°-102° in the first twenty-four hours. The pulse increases at the rate of about 10 beats per degree of temperature. The respiration rate increases because of chest pain and painful breathing and may lead to confusion with early pleurisy or pneumonia. The gall-bladder area is tender to touch. The point most markedly tender is beneath the right costal margin. If the tenderness is lower or near the umbilicus, it is due to inflammation in a low lying gall bladder or a retrocecal appendicitis. Here Ligat's sign will be of help. Rectal and recto-vaginal and vaginal examinations are made always. Laboratory examinations consist of complete blood count and urinalysis. The differential count is most important as a high polymorphonuclear count indicates an infectious process, and a low polymorphonuclear count in the presence of a low total white blood cell count means poor resistance and a bad prognosis. A few blood cells in the urine may be misleading and a negative urine erroneous. A scout x-ray film of every acute abdomen is taken in the upright and flat position as much information is obtained in this manner.

2. *Perforated Peptic Ulcer.*—This is rare in the female. The perforation may be the first symptom, but usually there is a history of peptic ulcer, gastric hemorrhage or food distress. The pain is severe and sudden and so intense that the patient doubles up and may drop to the floor. The pain causes the abdomen to become board-like rigid and the patient shows signs of shock. About one-fourth of the patients have shoulder pain due to phrenic nerve irritation. The abdomen is tense and tender, and point tenderness early will be above the umbilicus. Later it will be in the right lower abdominal quadrant. Appendicitis is frequently mistaken for ruptured peptic ulcer. Auscultation reveals a silent abdomen. The temperature is normal or subnormal at first. With peritonitis it rises. The pulse increases moderately and the respirations are 24 to 30 per minute, shallow and costal in character. The leukocyte count averages 15,000, and polymorphonuclear cells average 80 per cent. Leukopenia may be present. The urine is normal.

In 1908 Weinberger observed on x-ray film the accumulation of gas under the diaphragm, and Popper in 1915 reported a case in which he observed gas under the diaphragm by fluoroscopy. In about 70 per cent of the cases air can be demonstrated under the right diaphragm by fluoroscopy with the patient lying on the left side.

3. *Acute Pancreatitis.*—There are two types—acute hemorrhagic and acute edematous pancreatitis. The latter is the more mild and recovery usually occurs without therapy, while the former is associated with hemorrhage in the pancreas and fat necrosis, and prompt treatment is necessary. The history is usually similar to that of acute cholecystitis and it occurs more frequently in females of the stout type over forty years of age. It appears following the ingestion of a heavy meal. The onset of pain is dramatic, sudden, excruciating, and radiating to one or both loins. The pain is relieved when the patient sits up or lies on his abdomen. Reflex vomiting and retching occurs. Examination shows the patient to be in extreme pain, in semi-shock, with subnormal temperature, rapid, thready pulse, epigastric tenderness associated with muscular defense localized to the organ, most marked between the xiphoid and umbilicus; occasionally ecchymosis in one or both loins or at times around the navel due to extravasation of blood around the retroperitoneal space. Abdominal auscultation, a helpful diagnostic agent, usually reveals a quiet but not silent abdomen. Gage blocks the upper lumbar region with procaine and gets immediate relief for his patients and considers the procedure of positive diagnostic help. Laboratory work shows an elevated leukocyte count and glycosuria. A blood sugar above 300 milligrams per cent may be indicative of a fatal outcome. Elevated blood amylase is a positive test and becomes present in two to three hours after the onset of the attack. X-ray studies are not very helpful but separation of the upper and lower limb of the duodenum represents thickening of the pancreas.

4. *Ruptured Viscus (Liver or Spleen).*—If there is a history of accident or trauma, the patient may or may not present signs of shock and shoulder pain, either right or left, due to phrenic nerve irritation. Signs of internal hemorrhage are present and a diagnostic puncture of the abdomen is an important aid in deciding on urgent surgical interference. Liver dullness or splenic dullness is increased and x-ray will give evidence of an enlarged organ with displacement. The patient must be watched for late secondary hemorrhage. Laboratory findings suggest peritoneal irritation with leukocytosis and lowered hemoglobin values due to hemorrhage. Urinalysis will be negative.

5. *Coronary Disease.*—The surgeon cannot afford to make the fatal error of confusing an acute coronary disease with an acute abdominal condition. The coronary condition is more common in men past the age of forty, with a history of previous dyspnea and chest pain occurring during exertion. The pain may be sudden or gradual, increasing in severity, involving the upper abdomen and chest and radiating to the left arm or both arms or up the neck. There is fear and fright associated with the pain. There is a history of indigestion, belching, and bloating not related to foods. The attack may appear after a heavy meal.

Examination reveals possibly an enlarged heart, a soft slow pulse, low blood pressure, dilated neck veins, a flaccid abdomen and no point tenderness or muscle spasm. An elevated leukocyte count and sedimentation rate and a positive electrocardiogram reading are diagnostic, and these findings may be present the first twenty-four to forty-eight hours after the onset of the attack. X-ray reveals a negative abdomen and an enlarged heart. Urinalysis will be negative.

Common pathologic conditions occurring in the lower abdomen are:

1. *Acute appendicitis* is found more frequently in individuals under forty years of age and is somewhat more common in females. The patient usually first notices a "stomach-ache" and the druggist or good friend has prescribed a cathartic. If given the Two Question Test—(1) "Where was your pain when it started?" and (2) "Where does it hurt you now?"—the patient usually points to the epigastrium in answer to the first question and to the right lower quadrant in answer to the second question. This simple method will frequently diagnose the case.

Text books that teach that acute appendicitis can be diagnosed by pain, temperature, nausea, vomiting, and leukocytosis may be erroneous. Nausea and vomiting are the exception, not the rule, in appendicitis. Loss of appetite is a more constant sign and is due to early distention of the appendix. Wyatt states that a child with abdominal pain who can eat does not have appendicitis. Diarrhea and chills are rare in acute appendicitis and constipation is the rule. Fever is not an early finding but is present after peritoneal irritation has taken place. When the temperature has risen to 101° or 103°, localized or beginning generalized peritonitis has started already. Point tenderness is the most important sign in the diagnosis. With the patient lying on his back, pressure in the region of the inflamed organ will cause the patient to wince with pain and cause muscle spasm (both recti) due to a defense mechanism. Ligat's sign will be helpful and Rovsings' sign may be elicited by pressure on the left lower quadrant which forces gas along the colon against the cecum, causing pain over the cecum. It is found in 60 to 70 per cent of the cases. Rectal and vaginal examinations are important. Laboratory examination reveals a leukocyte count of 14,000 to 15,000 with a high polymorphonuclear cell count. However, occasionally, a gangrenous appendix will be associated with a normal count. Urinalysis may show occasional pus cells due to ureteral irritation. Flat plate of the abdomen helps in ruling out other abdominal conditions.

2. *Renal Colic.*—This may be due to stones, blood clots, urates or ureteral kink. The condition is most frequent in males and there may be a history of previous attacks, family tendencies, a story of gout or parathyroid pathology. The pain is sudden, severe and colicky, starting in the lumbar region, right or left, and radiating to the vulva or testicle. There is restlessness and thrashing about while the patient with peritonitis lies quiet. Vomiting and urinary frequency are common. During urination the colicky pain may be altered.

Physical examination rarely reveals an elevated temperature. Bradycardia is a common finding. A clean tongue and slow pulse in an acute abdomen is a renal condition until proven otherwise. Murphy percussion and tap is very painful.

Leukocytosis may be present. Blood, pus, and albumin are found in the urine. However, a stone may block completely a ureter and produce a negative urine. X-ray examination may reveal a stone present though non-opaque substances may cause the renal colic.

3. *Gynecologic Disorders.*—In considering other conditions of the lower abdomen, the general surgeon must be bold enough to invade the field of the gynecologist. Here, such conditions as acute salpingitis, twisted ovarian pedicle and ruptured ectopic pregnancy are most frequent. The diagnoses are made by the same plan of attack.

4. *Diverticulitis.*—There is a history of irregularity of bowel habits and at times colicky intestinal cramps and pain in the lower abdomen. The condition is more common in males. Course and rough foods cause intestinal irritation. During an attack there is leukocytosis, moderate fever, distention of the abdomen and bloating. X-ray examination with a small amount of barium will prove the diagnosis.

Case 1.—Mrs. E. M., a white woman, aged sixty-six, had a history of repeated attacks of right kidney infection for fifteen years. At one time she passed a kidney stone. Present illness started two days previous to hospital admission with pain in the right kidney region and frequency and burning of urination. There was no history of any food distress but there was nausea. Temperature was 102°, pulse 80 on admission.

Examination revealed a somewhat distended though flaccid abdomen. There was no point tenderness except the tenderness over the right kidney on Murphy percussion. There was some tenderness on deep palpation over a lower right rectus scar. Vaginal examination was negative.

The urinalysis showed two plus albumin, 40 to 50 pus cells, and 5 to 10 red cells. The white blood cell count was 19,800, 85 per cent polymorphonuclear cells, 15 per cent lymphocytes. X-ray revealed definite distention of the large and small bowel. The kidney shadows were normal but some calcifications in the right pelvis which might be phleboliths. The impression was acute pyelitis, possibly kidney stone passing. On the third day in the hospital the patient became very distended and complained of severe pain in the right costal region with point tenderness. Exploratory laporotomy revealed a perforated gall bladder full of stones, free bile in the peritoneal cavity. Drainage was instituted. The patient ran a stormy course. She developed pneumonia with empyema. Death ensued. The autopsy revealed localized peritonitis, sub-diaphragmatic abscess, empyema, and pyelitis.

Case 2.—Mr. M. S., a white man, aged sixty-three, had a negative past history as to stomach distress or indigestion. The present illness started shortly after arising in the morning with an acute upper abdominal pain. This was his first attack of stomach trouble. He vomited several times. Examination revealed a board-like, rigid upper abdomen. There was localized tenderness above the navel line. Negative urinalysis. There were elevated white cell and polymorphonuclear cell counts. X-ray findings and fluoroscopy of the abdomen revealed a small amount of air under the right diaphragm. Laporotomy verified the diagnosis of a perforated duodenal ulcer. The post-operative course was uneventful.

Case 3.—Mr. N. H., a white man, aged forty-nine, was seen in consultation the second day after his admission to the hospital. He had a distended abdomen. There was moderate tenderness in the left pelvic region. Rectal examination revealed a mass in the left pelvic region. The urinalysis was negative. The white cell count was 15,900, with 80 per cent polymorphonuclear cells. The x-ray revealed loops of distended bowel with gas in the colon and lower bowel. Conservative treatment was continued. Twenty-four hours later the patient became worse and exploratory laparotomy revealed a ruptured appendix with ileum obstructed due to an abscess and exudate in the pelvis. Appendectomy was done, leaving an indwelling ileostomy tube. The postoperative course was stormy, but the patient recovered.

Case 4.—Master W. M., a white boy, aged six, was struck by an automobile and received a concussion, bruises to the lower right chest and upper abdomen. He entered the hospital semi-comatose Examination revealed multiple abrasions on the boy's head and lower chest. The urinalysis was negative. Hemoglobin was 74 per cent. The white cell count was 14,000, with 78 per cent polymorphonuclear cells. X-ray of the abdomen on admission showed nothing of note. When seen in consultation two days later the lower right chest revealed dullness. There was increased liver dullness. The hemoglobin was 66 per cent. The red cell count was 3,100,000 and the white count was 15,600. X-ray showed the liver to be increased in size. A needle was introduced in the abdomen and revealed no intraperitoneal blood. The boy was transfused and treated conservatively and recovery was uneventful. A diagnosis of intracapsular hemorrhage of the liver was made.

Case 5.—Mr. A. S., a white man, aged fifty, had been under my observation for several years with a duodenal ulcer which had been inactive for the past fifteen months. Present illness of stomach distress had appeared five days prior to hospital admission while on a hunting trip. Four hours before entering the hospital he developed severe abdominal pain around the navel with nausea and vomiting. His wife said he nearly fainted because the pain was so severe.

Examination revealed a board-like abdomen above the navel and along the right side with point tenderness in the right lower quadrant. The urinalysis was negative. The white cell count was 16,500, with 80 per cent polymorphonuclear cells. Flat plate of the abdomen was negative for air. A diagnosis of ruptured appendicitis was made and a lower right rectus incision revealed a retrocecal ruptured appendix. Appendectomy without drainage was performed. The postoperative course was uneventful.

Case 6.—Mrs. O. S., a white woman, aged thirty-seven, had been bleeding for two weeks prior to hospital admission. When seen by myself she gave a history of no missed periods or irregularity until the present bleeding episode. She had had two children living and well, the youngest being fifteen years of age. Examination revealed the patient in severe pelvic pain. The pulse was soft and rapid. Blood pressure was 100/80. There was marked tenderness in the right lower quadrant. Pelvic examination revealed a retroverted uterus and a tender, boggy mass in the right cul-de-sac. The patient refused needle puncture. The white cell count was 22,500, with 86 per cent polymorphonuclear cells. A flat plate of the abdomen gave no information. A laporotomy verified the diagnosis of a ruptured ectopic pregnancy. The postoperative course was uneventful.

Case 7.—Mrs. K. A., a white woman, aged fifty, had been admitted thirty-six hours prior to the time I saw her in consultation. She gave the history of intermittent cramps of the lower abdomen associated with the appearance of menstrual blood. She had been operated upon twice in the past for appendicitis in childhood and had had a pelvic laporotomy eight years previously. Nasal suction had been started on her admission to the hospital, which gave her a small amount of relief until 6:00 a.m. of the day I examined her. When seen at 10:00 a.m., her pulse was 140 and blood pressure was 80/50. The skin was cold and clammy. The abdomen was moderately distended and there was a tender palpable mass in the left lower quadrant the size of a child's head. There was a right rectus and midline scar. Pelvic examination revealed a bloody discharge and a tense, tender palpable mass filling the left pelvis. A catheterized specimen of urine was normal. The white cell count was 18,600, with 88 per cent polymorphonuclear cells. A flat plate of the abdomen revealed a mass in the left lower abdomen and two large stones in the bladder. A diagnosis of twisted ovarian pedicle with gangrene or gangrenous bowel from an obstruction or mesenteric thrombosis was made. The patient's condition was critical and in spite of multiple portals of blood and fluid she remained in shock. Emergency exploratory under spinal anesthesia revealed multiple pelvic adhesions. Three loops of gangrenous small bowel, 72 cm. in length, held in the pelvis by an adhesive band to an ovarian cyst were liberated, resected, and an end-to-end open anastomosis was performed. As soon as the grangrenous bowel was excised the patient's condition improved. Her pulse lowered to 110 and a gradual rise in her blood pressure changed the entire picture. The abdominal tissue, which had been cold, began to warm. She left the operating room in fair condition and her postoperative course was uneventful.

Summary

1. Pitfalls in acute abdominal diagnosis are made when we confuse the more common disorders with the many possible abdominal catastrophies.

2. I have tried to simplify diagnostic procedures by a planned method:

(a) Dividing the abdomen in two planes.

(b) Correlating the clinical and laboratory findings.

3. A case report has been given to represent each of the more common acute abdominal conditions.

Discussion

Dr. Hamlin Mattson: Development of chemotherapy and antibiotics has permitted more deliberation in cases where the diagnosis is obscure in acute abdominal conditions. In some instances nonoperative treatment is possible where before operation was considered imperative.

An example in point is perforated duodenal ulcer. When sulfonamides only were available, slow leaks on an empty stomach were treated occasionally with suction siphonage and chemotherapy.

In February, 1939, I saw a woman, aged forty-five, who had a fairly typical history and findings of ruptured duodenal ulcer with gas demonstrable under the right diaphragm. The rupture occurred about four hours after a meal, the area of peritoneal irritation was limited and with some temerity I treated her nonoperative as indicated above.

Infections have accounted for most of the fatalities in ruptured peptic ulcer. In 1937, Bergh, Bowers, and Wangensteen made one centimeter long incisions in the stomachs of animals. Those incised when the stomach contained food showed an 86 per cent mortality. Of those incised with empty stomachs only 6.8 per cent died. The mortality rate from perforated peptic ulcer has declined rapidly in the past years. Trieger in 1947 reported a 33 per cent mortality in 73 cases from 1930 to 1944 and no deaths in seventeen cases from 1944 to 1946. Others have reported similar results.

In 1946, Taylor of London reported trial of nonoperative treatment. In twenty-eight cases there was a 14.3 per cent mortality. Seeley in 1949 reported thirty-four cases with no mortality.

About a year ago, Bingham set forth the following criteria for non-operative treatment of ruptures:

1. Less than eight hours old, or more than three days
2. More than one hour since last meal.
3. Duodenal rather than gastric.
4. Small perforation.
5. Where the differential diagnosis is uncertain.

PROBLEMS IN ACUTE INTESTINAL OBSTRUCTION

LEO C. CULLIGAN, M.D., F.A.C.S.

Minneapolis, Minnesota

In discussing acute intestinal obstruction there are several physiological considerations that should be taken up. The first of these is fluid and electrolyte loss. When the obstruction is high and vomiting is profuse this loss may be enormous. A patient may lose up to 8,000 c.c. daily with a corresponding loss of sodium and chlorides. When obstruction is at the pylorus, profuse vomiting may throw a patient into alkalosis and even into gastric tetany. Fluid replacement containing as high as 20 to 30 grams of salt may be necessary to replace the loss of electrolytes. The response in these cases is dramatic.

The farther down the intestinal tract that the obstruction is located, the less one need worry about electrolyte loss. Then one must consider primarily the effects of distention. In an obstructed bowel the first thing that occurs is the accumulation of large amounts of gas. This gives the characteristic x-ray of small bowel obstruction. Later the accumulation of fluid in the distended loops may replace the gas almost entirely and often gives a confusing x-ray picture unless one gets an upright film which will show fluid levels in the small bowel loops.

Distention is the most lethal factor in simple (non-strangulating) obstruction. If prolonged, it can initiate mucosal degeneration as shown by hemorrhage, erosion and ulceration. Marked distention can so compromise intramural blood flow as to endanger viability of the bowel. While the exact mechanism is not known, distention is thought to have much to do with the absorption of toxins from the obstructed bowel, for the relief of distention improves the general condition of the patient markedly.

The third most important physiological consideration is the effect of interference with the blood supply of a loop of bowel producing a strangulation obstruction. It is this factor that makes hazardous the non-operative or conservative treatment of mechanical obstruction by means of gastrointestinal tubes. It is often difficult to recognize strangulation obstruction even when the patient is being carefully watched and the surgeon is on the lookout for it. Interference with the blood supply to a loop of bowel is soon followed by loss of viability of the mucosa with resulting invasion of bacteria into the intestinal wall and through the serosa into the peritoneal cavity. Later frank necrosis and perforation may occur with gross peritoneal contamination.

In strangulation obstruction there is often enough blood loss into the lumen of the bowel and into the peritoneal cavity to account for some of the shock associated with intestinal obstruction.

While it is difficult to lay down any general rules of treatment because of the many varied causes of obstruction, it is pretty well agreed that acute obstructions of the small bowel requiring resection should be treated by immediate end-to-end anastomosis whereas acute obstruction of the large bowel should be best treated by colostomy—transverse colostomy if possible. An exception to this is acute obstruction of the right side of the colon which also can be treated safely by immediate resection and end-to-end ileo-colostomy.

Causes of Intestinal Obstruction

(In order of frequency)

A. Small Bowel

1. Adhesive bands
2. External hernia
3. Intussusception
4. Obturator
    a. Gallstones
    b. Foreign body
    c. Worms
5. Vascular
    a. Thrombosis
    b. Embolus
6. Congenital atresia
7. Volvulus
8. Neoplasm
9. Internal hernia

B. Large Bowel

1. Neoplasm
2. Volvulus
3. Diverticulitis
4. Adhesive bands

The manifestations of acute intestinal obstruction are so varied and complex that I felt that the subject could be best covered by concrete examples of cases illustrating diagnostic and therapeutic problems.

Case 1.—A man, aged seventy, early on the morning of August 13, 1949, experienced a pain and swelling in the right groin. He vomited and had what he described as a gas pain.

In mid-afternoon a strangulated right inguinal hernia was reduced by his physician. The pain persisting, he was sent to the hospital.

Late in the afternoon when he was seen in consultation, there was no swelling and no pain. Operation was not advised.

Three days later the patient was discharged from the hospital, a flat plate of the abdomen having been negative and the leukocyte count being normal.

This patient had a strangulated hernia with symptoms of bowel obstruction for a period of eight to ten hours. He had gas pains, vomiting, local tenderness and swelling. The patient was much opposed to an operation, and in view of the fact that he had reached the age of seventy before the hernia had caused him any symptoms, and because at the time I examined him, about one hour after the hernia had been reduced, he was completely free of symptoms, I agreed to forego an operation and instead we elected to observe him.

We kept him in the hospital and ran daily leukocyte counts for four days. These were normal. On the third day we had a flat plate of the abdomen which was entirely negative so the patient was discharged. If confronted with the same problem, I believe that one should strongly urge an operation. The uncertainties regarding the viability of the strangulated loop are too much to risk even when the patient is watched carefully. When contrasted with the next patient, this case takes on a more special interest.

Case 2.—A woman, aged sixty-six, a poor cardiac risk, had been operated upon by another surgeon on October 10, 1948, for a strangulated femoral hernia. A loop of bowel of questionable viability had been left.

A leukocytosis of 20,900, 20,850, and 18,700 persisting on October 12, 13 and 14, and a flat plate taken October 14 showing the small bowel distended with gas, the patient was reoperated upon. A necrotic loop of small bowel was resected and an end-to-end anastomosis made.

The patient died suddenly of a heart attack while out of bed on the fourth day following the second operation. An autopsy showed the anastomosis patent and the peritoneum clean.

Here again we are confronted with the problem of determining the viability of a loop of bowel inside the abdomen. The patient was an extremely bad heart risk who had been treated many times for cardiac decompensation by the surgeon who operated upon her for the strangulated femoral hernia. At the time of operation, after observing the bowel for some time, he felt that it would be viable and dropped it back. He was, however, worried about its status and asked me to follow her progress with him.

In such a situation you usually have a few days before an inviable bowel will rupture. Daily leukocyte and differential counts were taken. As shown in the case report these remained consistently high, around 20,000. Clinically there was some distention and tenderness, although the patient was quite obese and examination was unsatisfactory. A flat plate of the abdomen on the fourth day showed small bowel distention. In view of these findings, the patient was reoperated upon on the fourth day. The loop of bowel was found to be necrotic—so soft that we feared it would rupture as we removed it.

A closed type of end-to-end anastomosis was carried out. The patient was out of bed. Suddenly, on the fourth day after her second operation she had a heart attack and expired.

The lesson to learn from these two cases is that if you drop back a loop of questionable viability, order daily leukocyte counts and get frequent flat plates of the abdomen. If the white counts remain persistently high for a few days, and if you can rule out any other complication which might raise the leukocyte count, you had better open up the patient and look again.

In addition to the usual signs of determining bowel vialibility at the time of operation, such as the return of color, arterial pulsations and active peristalsis, there are a few other aids that have proven helpful. Fluorescein solution given intravenously will show up as a green fluorescence in a viable bowel observed under ultraviolet light. Laufman and Method measured the surface temperature of the bowel and found that the temperature of a strangulated bowel was subnormal. When the strangulated mechanism was released, if the bowel was viable, the temperature would return to normal or above. If, however, the bowel was inviable, the temperature would remain subnormal. They also found that papaverine given at the time was helpful in overcoming venospasm and aided in the recovery of the bowel if it could survive. Arnold Kremen has called attention to the fact that the return of peristalsis is not always a reliable guide, for it may be simulated by active muscle contractions due to anoxemia.

Case 3.—A man, aged sixty-two, who was diabetic, was admitted to the hospital on January 16, 1949, six days following strangulation of an umbilical hernia.

The patient was very obese and distended on admission. A large umbilical hernia was red and phlegmonous and suggested a strangulated and necrotic bowel.

The same day the hernia was removed in toto without entering the sac. An aseptic end-to-end anastomosis of the distended and collapsed loops as they entered and left the hernia sac was made (method of Dennis and Varco).

Recovery was uneventful.

This patient lost a leg in a railroad accident and had been retired for years, during which time he had become extremely fat. He had an umbilical hernia for a long time which had given him no trouble. Six days prior to admission to the hospital this could no longer be reduced and his bowels stopped moving. The swelling slowly became red and tender. Examination showed a large umbilical hernia the size of a grapefruit that was red, edematous and septic from the enclosed gangrenous bowel. The rest of the abdomen was distended but soft. X-ray showed distended loops of bowel. We knew that if we once opened into this septic sac our patient would probably die of peritonitis. So using the method described by Dennis and Varco for strangulated femoral hernia, we encircled the hernia with our incision, excised the hernia in toto, resected the bowel as it entered and left the sac, removing the hernia with its encircling ring without any contamination whatsoever. An end-to-end anastomosis was carried out. To take pressure off the suture line we asked Dr. Wild to pass an intestinal tube following the operation. The postoperative convalescence was normal.

Case 4.—A woman, aged twenty-seven, had a normal delivery on September 28, 1945. Vague abdominal pains began on October 4, 1945, and occasionally emesis occurred. Temperature and pulse were normal.

On October 10, 1945, the patient suddenly went into shock. She was seen in consultation that day and appeared in moderate shock, with the abdomen rigid and distended. X-ray of the abdomen showed small bowel distention. The leukocyte count was 17,000, with 92 per cent polymorphonuclear cells.

The same day the abdomen was opened, and a strangulated loop of gangrenous small bowel, 129 cm. in length, was found caught under a band of adhesions. Resection was performed and an aseptic end-to-end anastomosis made.

This case illustrates the difficulty in diagnosing intestinal obstruction that develops during the postpartum period. During that time both the physician and the patient expect that she will have a certain amount of abdominal pain. This patient's postpartum period was normal up to the sixth day. She then began having crampy abdominal pains that persisted for four days, never severe until during the night of the tenth postpartum day. Then suddenly she went into shock. When I was asked to see her, the abdomen was rigid and distended, pulse was rapid and blood pressure low.

As soon as shock was corrected she was operated upon. A loop of bowel, 60 inches long, was found under a band. This was black and inviable. A closed type of end-to-end resection was done about 3 inches from the ileocecal valve. Postoperative convalescence was uneventful except for loose stools that persisted for about two months.

Case 5.—A woman, aged forty-six, was found to have a carcinoma of the transverse colon in the course of an operation on December 23, 1948, for supposed appendicitis. I was asked to assist and found a greatly distended cecum due to the obstructing carcinoma.

The carcinoma and proximal transverse colon and cecum were removed, and an aseptic end-to-end anastomosis between the ileum and distal transverse colon was made.

The patient was discharged on January 10, 1949, in good condition.

Complete obstructions of the right colon present a most acute emergency and require immediate surgical relief. The cecum is thin-walled and with the ileocecal valve usually remaining competent; it then becomes a closed obstruction comparable to a strangulated loop, and blowouts occur early and frequently.

Ordinarily it is generally agreed that definitive surgery should not be carried out in acute obstructing lesions of the large bowel. Acute obstructions of the right colon, however, are an exception to this rule. Here it is possible to remove all the obstructed portion of the colon together with the growth and make our anastomosis between normal collapsed distal colon and the terminal ileum. This can be done even if the small bowel is distended, for we know that there is usually no difficulty encountered suturing into the wall of obstructed small bowel. Removal of the tense cecum may be facilitated and distention of the terminal ileum may be relieved by using the aseptic suction enterostomy of Wangensteen, inserting it after the abdomen has been opened through the wall of the terminal ileum down through the ileocecal valve into the cecum. If one has already passed a gastrointestinal tube into the lower ileum this may be passed through the ileocecal valve into the cecum and thus decompress it.

Case 6.—A man, aged sixty-seven, experienced colicky lower abdominal pain at hourly intervals beginning August 13, 1945. On the following day there was marked abdominal distention with rigidity. A flat x-ray plate of the abdomen showed a coffee-bean distention of the sigmoid.

At operation on August 14 a volvulus of the sigmoid colon at the peritoneal reflection was resected and a primary end-to-end anastomosis made.

The patient was discharged on October 5, 1945.

This patient whom I operated upon at General Hospital is interesting for several reasons. His gas pains were characteristic of colon obstruction. His colics, instead of coming every five to ten minutes as they usually occur in small bowel obstruction, came hourly. His flat plate was beautifully characteristic of volvulus and his local findings of tenderness and marked rigidity and distention gave one no choice as to proceedure. At operation the volvulus was completely black and gangrenous and extended from the pelvic floor to the left rib margin. The twist was located at the peritoneal reflection and was too low to allow exteriorization so an end-to-end anastomosis was carried out. This patient's plasma proteins were very low and he completely eviscerated on the eighth day. He was taken back to the operating room and the abdominal wall was resutured. His subsequent convalescence was normal.

A couple of years ago Dr. Brunsgaard of Norway spent some time at the University and interested those who heard him speak before this society in his method of reducing volvulus by means of a proctoscope with the insertion of a soft rubber tube into the volvulus. He reported 136 successful treatments with four deaths. He cautioned that one must not try the method where there is any indication or question of impaired circulation or gangrene. While exteriorization by Michulitz procedure has usually been recommended as the operative procedure of choice in volvulus, he contends that the twist is usually too low to permit this type of operation, as was true in our case, and he recommends the inversion and burying of the distal stump and the making of a colostomy of the proximal end with re-anastomosis later.

In every obstruction of the colon, volvulus must be considered. It causes about 16 per cent of colon obstructions and, unless relieved, gangrene with perforation will usually result. It can easily be overlooked if one makes a transverse colostomy to relieve sigmoid obstruction and assumes that the obstruction there is due to carcinoma. A flat plate usually gives a characteristic picture, as does also a barium enema.

Dr. Baronofsky has been interested in this problem at the University of Minnesota. His feeling is that if there is evidence of gangrene that it is not safe to reduce by tube and proctoscope and that one should do an immediate resection and end-to-end anastomosis. If there is no evidence of gangrene, he feels that the volvulus should be reduced by Brunsgaard's method, and after several days, one should resect and do an end-to-end anastomosis.

These last five cases where bowel resection was carried out in the face of acute obstruction due to varied causes recommend strongly the closed type of anastomosis.

Throughout the country there is still considerable argument between the proponents of the open and the closed types of bowel resection. Personally I have used the closed method of resection in practically every case of bowel resection that I have done during the last ten years, and I am convinced that anyone who gets accustomed to using it will not abandon it for the open type of resection.

While the antibiotics have given the open type of resection a greater degree of safety, one should not rely on them completely for protection. I recently operated for a ruptured appendix. In spite of massive doses of penicillin, streptomycin and intravenous aureomycin, the patient developed three intra-abdominal abscesses that had to be drained. Moreover, experimental work has shown that there is firmer healing where there is no serosal contamination at the time of operation. Also, contamination of the peritoneal cavity, while it may not be serious in the unobstructed case, may attain real magnitude in the acutely obstructed patient, for that patient does not tolerate soiling of any degree. Moreover, when it is necessary to anastomose loops of bowel of different sizes, as is necessary in doing an end-to-end anastomosis between a large distended loop of small bowel to a small collapsed bowel, or when one unites small bowel to colon end-to-end, this can be done very easily when one does it over clamps. By varying the angle that the clamp is placed on the two loops of bowel, one can easily make the opening the same size in the ends to be joined together.

The arguments of those who advocate the open anastomosis hold true for the most part only in those cases where one has the time and opportunity to preoperatively sterilize the bowel content. In the five cases which we have just presented we had no chance to prepare the bowel. In all of these, done in the face of acute obstruction where haste was essential, the closed type of resection stood us in good stead. To me, they represent situations where the closed type resection attains its greatest value and gives your patient a protection from infection that you cannot give him in any other way.

Since Dennis published his artcile in 1943, I have used his method in bowel resection almost routinely and I like it very much. Using it, no end-to-end anastomosis has failed to open on scheduled time, and except for the patient cited here who died of a heart attack four days after operation, I have had no deaths. His method differs from others in that it requires a 45° rotation of each end of the bowel in opposite directions so that the mesentery of the distended loop will be on the opposite side to that of the collapsed loop. This means that in an end-to-end anastomosis instead of ending up with a junction with a 90° angle as is customary, one ends up with a straight tube.

Case 7.—A woman, aged thirty-nine, for two weeks ran a septic course with right abdominal pain and developed a mass in the right side of the abdomen.

On October 19, 1948, she was admitted to the hospital. The pain, mass and septic temperature persisted. Sulfasuxidine was started. A flat x-ray plate showed a mass on the right side and a dilated small bowel.

A barium enema on October 20 showed a narrowed terminal ileum. A flat plate on October 22 showed increasing small bowel distention.

At operation on October 22 a regional ileitis was found, with an abscess between the ileum and cecum. This was resected. An end-to-end anastomosis was made between the ileum and the transverse colon.

The postoperative temperature never went over 99.2° and the patient was discharged on January 30, 1948.

We present this case because it allowed us to accomplish something which was unique in our experience. At the time of operation we found dilated loops of small bowel terminating in a mass between the last foot of small bowel and the ascending colon. There, protected by the agglutinated bowels anteriorly and laterally and sealed by the parietal peritoneum posteriorly, was an abscess. Starting along the lateral wall of the ascending colon and getting into a line of cleavage behind the visceral peritoneum, we were able to remove the terminal ileum, cecum, ascending and right part of transverse colon which enclosed the abscess without rupture. An end-to-end anastomosis was carried out. Her temperature subsequent to operation never going over 99.2° is indicative of her uneventful convalescence. It is only on the rarest occasions that the anatomy makes it possible to remove an intra-abdominal abscess intact.

The results of surgical treatment of regional enteritis are notably poor. There is much argument whether one should do only a short circuiting operation or a radical resection of the diseased tissue. Operation should be postponed until the late stages of the disease and should be used primarily in the treatment of complications—obstruction, abscess, hemorrhage, fistulas, et cetera.

Case 8.—A woman, aged seventy-six, had a sudden onset of colicky abdominal pains with vomiting on November 24, 1947.

The colicky pains persisted the next day without flatus being expelled.

A flat x-ray plate of the abdomen taken November 26 showed a distended small bowel.

On November 28 a flat plate showed gas in the biliary tract.

On November 30 a flat plate showed the gas in the small bowel practically gone but much in the colon. On that day a gallstone 1.5 inches in diameter was extracted from the rectum.

An x-ray on December 1 showed that barium, taken orally, appeared in the biliary tract. The patient was discharged that day.

In the diagnosis of gallstone obstruction the most important thing is that it be considered as a possibility. If one thinks of it, it may be possible to work out a preoperative diagnosis. Until recent years the diagnosis preoperatively was indeed a rarity. Rigler and Borman called attention to air in the biliary passages as indicating the presence of a fistula between the bowel and the biliary tract. Clinically an obstruction that relents and recurs should suggest obturator obstruction. Tenderness is often present when gangrene is starting over the gallstone at the site of obstruction.

Treatment is usually early surgery though occasionally, as in this case, it is not necessary. There is no doubt in my mind that many gallstones pass through the fistula and the bowel, causing only partial obstruction without many symptoms.

Case 9.—A woman, aged forty, had an ovarian cyst removed by a gynecologist on November 25, 1947.

On December 1, 1947, she experienced mild gas pains. They became more severe two days later and were accompanied by emesis. A flat x-ray plate showed distended loops of small bowel.

On December 3, 1947, the patient was seen in consultation. A second operation was performed, and about two feet of the middle portion of the ileum were found glued together by firm adhesions. These were separated.

Convalescence was uneventful.

Obstructions occurring during the postoperative period always present a most difficult problem. This case is presented because it not only is unusual that such firm plastic adhesions should have formed so early, on the ninth day following operation, but also to show the change that has taken place in my feeling about the treatment of simple small bowel obstruction. A few years past we probably would have been content to treat this patient conservatively by an indwelling Levine or gastrointestinal tube—at least for a day or two. Instead, we operated on this patient within a few hours after seeing her. On finding the firm plastic adhesions that caused marked obstruction we had no regrets for doing so.

It is my feeling that in spite of the progress that has been made in making more efficient gastrointestinal tubes and better methods of getting them through the pylorus, that there is a definite trend away from the conservative therapy of intestinal obstruction. While conservative therapy using intestinal intubation often relieves the obstructing mechanism in adhesive obstruction, it is a blind uncertain method even when followed carefully with flat x-ray plate and leukocyte counts. Using this type of therapy one can very easily miss a necrosing adhesive band, a gallstone obstruction, an internal hernia, mesenteric thrombosis, intussusception, volvulus, et cetera. That this change of policy is taking place at the University of Minnesota which has been the center of conservative therapy in simple small bowel obstruction is shown by the following two quotations. Dennis in October 25, 1946, in the *Bulletin of the University of Minnesota Staff Meeting* states, "the general policy at the University hospital is to treat these cases of small bowel obstruction which appear simple, by nasal suction syphonage without operative interference." Dennis in October, 1949, in *Surgical Clinics of North America* states, "with our recent adoption of exploration of nearly all cases of small bowel obstruction, early recognition of strangulation has assumed less importance."

And there are good reasons for this change of attitude. For while the hazards of conservative therapy in simple mechanical obstruction remain constant, the dangers of operation have steadily lessened. Better anesthesia, the antibiotics, and the use of blood have been helpful here as in all types of surgery. Specifically, however, there are three major advances which have had a real influence. One of these is the aseptic suction enterostomy of Wangensteen which allows one to deflate distended loops of bowel so that one can see the obstructing point and can get at it without injuring distended loops of bowel. This is particularly useful in dealing with adhesive bands located in the pelvis.

The second is the aseptic resection method of Dennis which permits of easy end-to-end anastomosis in loops of bowel of different size. This can be used with little danger of peritonitis in acute obstructions where there has been no chance to prepare the bowel.

The third factor is the development of a better type of gastrointestinal tube and better methods of introducing same. Dr. John Wild has brought out a gastrointestinal tube that is a real improvement. The chief reason for this is that it has only one large suction opening protected on one side by the mercury sac and on the other by the air balloon so that the wall of the bowel is not sucked into the opening, thus plugging it. When this tube is used as an adjunct to the operative treatment of acute small bowel obstruction, it lends a margin of safety that really is a factor. For there is no question but that a well functioning gastrointestinal tube can overcome the toxic effects of distention better than any other method, and it has been amply demonstrated that distention is the major lethal factor in the cause of death in acute intestinal obstruction. For it has been shown, that even in the face of complete obstruction that toxemia and shock are not likely to occur if distention is controlled. Unless a well functioning gastrointestinal tube is used in conjunction with surgery, the toxic effects of distention may persist several days before the bowel can sufficiently regain its tone of function again.

One trouble in the past has been that we have used the tube to treat the obstruction instead of using the tube merely as a means to relieve distention. The fact that at times adequate decompression may so alter the obstructing mechanism so as to allow the obstruction to relent does not alter the fact that suction drainage is actually a means of controlling distention and as such it should be used.

If we keep this thought in mind we can place the intestinal tube in its proper place in our armamentarium used in the treatment of intestinal obstruction. As mentioned above, it has real value when used as an adjunct to the operative treatment of intestinal obstruction. Here it may be either introduced before operation where we may be able to quickly decompress distended loops and thus make our operation easier, or continuing with it or introducing it after operation, we can use it to offset the toxic effects of distention until such time as the bowel can take over its normal function again, often a matter of 4 to 5 days.

Intestinal intubation is the treatment of choice in neurogenic ileus. Here it has almost completely replaced catheter enterostomy for it functions better and is far safer. By a well functioning tube the patient is protected from the lethal factor of distention until such time as the bowel has recovered from the shock that has upset its nervous mechanism and has again started to function.

Another ideal place for the use of the intestinal tube is where an inflammatory mass or a diffuse peritonitis may cause either ileus or mechanical obstruction. In these cases if we can protect our patients from distention, we can tide them over while we use the powerful antibiotics that we now have at our command to control infection.

Dr. Grafton Smith has a new gastrointestinal tube with a removable obturator made up of three wires one of which is used to stiffen the tube and the other two are used to guide the tip in various directions. Using this under fluoroscopic guidance or on the operating table it is possible to direct the tip of the tube in practically any direction. It looks like the best yet.

Case 10.—A woman, aged fifty-eight, dated the onset of lower abdominal pain to the time she had been catheterized at the office of a urologist (November 5, 1948).

She was admitted to the hospital on November 8, 1948. There was marked abdominal distention. A cystogram failed to show any perforations of the bladder. A flat plate showed small and large bowel distention. A barium enema failed to show any obstruction in the colon.

A diagnosis of ileus was made and a Wild intestinal tube was inserted. The bowel was deflated in six hours, after which a mass could be felt in the appendix region.

No operation was performed and the mass subsided.

This last case represents a situation where the gastrointestinal tube demonstrated its effectiveness as a means of combating ileus secondary to an inflammatory mass. It had so well decompressed a markedly distended bowel in about six hours time that we were able to feel the appendicial mass and make a definite diagnosis.

In conclusion. if I were to make one plea or to leave one thought it would be for the more judicious use of both Levine and gastrointestinal tubes. A tube should never be put down before you make your diagnosis. As soon as a tube is inserted the picture changes, the patient improves and the physician relaxes. Let the clinical picture develop until you can make a diagnosis. Use every clinical and laboratory and x-ray help that you can command. Then, if you use a gastrointestinal tube, you should do it with a definite therapeutic purpose in mind. If you elect to treat a mechanical obstruction with a gastrointestinal tube, do it realizing that you are walking on thin ice and that you can easily fall into deep trouble.

Meeting of February 3, 1950

At this meeting, the twenty-eighth anniversary dinner meeting, Dr. Warren H. Cole, professor of surgery, University of Illinois, presented a paper entitled "Benign and Malignant Goiter."

Meeting of March 2, 1950

At this meeting Dr. Lawrence M. Larson and Dr. John H. Rosenow presented "Solitary Pyogenic Liver Abscess—Review of Literature and Report of Case." Dr. A. A. Zierold presented "Operating Room Cholangiograms."

Officers were elected as follows: Dr. Harvey Nelson, president; Dr. Robert P. Caron, vice president; Dr. Albert T. Hays, recorder for three years, and Dr. Robert F. McGandy, member of Council for five years.

William H. Rucker, M.D., *Recorder*

Woman's Auxiliary

DR. JUDD SPEAKS AT AUXILIARY WORKSHOP

Mrs. Leonard S. Arling

Approximately 100 county officers and state board members of the Woman's Auxiliary to the Minnesota State Medical association attended the third annual Workshop meeting, October 16, at the Saint Paul hotel.

After the morning board meeting, Auxiliary members heard an inspiring address by Dr. Walter H. Judd, Congressman from the Fifth District, "A Prescription for a Healthy Government." Highlights of Dr. Judd's talk are these:

"I have been thinking much lately of Abe Lincoln's remark at Gettysburg—'We are engaged in a great Civil War, testing whether that nation, or any nation, so conceived and so dedicated can long endure.' Early Americans knew what made this country great, but do the succeeding generations understand what made the American system of government strong? Never has our system of government—the system our forefathers left Europe to found—been in such danger. Our system of government puts primary concern upon the many—government from the bottom up. Our system releases the great creative capacities in each individual. Would a bureaucratic dictatorship select a half-illiterate garage mechanic (Henry Ford) to put the world on wheels? Or would a half-deaf butcher (Edison) have been asked to light the world and produce the phonograph and the movies?

"We are in the midst of a great world conflict and also a conflict within America—the struggle between two philosophies of life: one, that the state should guarantee happiness, security, and keep absolute control of the individual, and two, that the state should only guarantee the right of the individual to pursue happiness, to have the freedom to take risks, to make his own decisions.

"Doctors and their wives have an obligation as citizens of our republic—

Six Obligations

"1. Don't be a radical who says that three-fourths of Americans can afford adequate medical care, one-fourth cannot, therefore let's throw out the whole thing and start over with compulsory health insurance.

"2. Don't be a conservative and say that nothing is wrong.

"3. Be a progressive conservative and strive to keep what is good, continuing to improve what is bad.

"4. Work night and day to show that which is good in our government.

"5. Speak out for the things we believe.

"Karl Marx' ideas changed the world. We can do it constructively as others do it destructively.

"6. Doctors and their wives should help select candidates, work in county and district and state caucuses to nominate candidates. Doctors and their wives should help elect candidates by voting themselves and seeing that others get out and vote."

Mrs. Waas Presides

Afternoon speakers were Mrs. Harold F. Wahlquist, Minneapolis, president-elect, Woman's Auxiliary to the American Medical Association: "Medicine's Educational Program;" Miss Helen K. Johnson, Saint Paul, assistant medical claims manager, Minnesota Medical Service: "Growing Pains;" Allan Stone, Saint Paul, executive director, Minnesota Division, American Cancer Society;" Mrs. James P. Tyrell, Saint Paul, chairman, Board of Directors, Antone Guild: "Our Lady of Good Counsel Cancer Home;" and the main speaker, Mrs. Leo J. Schaefer, Salina, Kansas, first vice president, Woman's Auxiliary to the American Medical Association: "The Auxiliary at Work."

The educational film "Breast Self-Examination" was shown.

Mrs. Charles W. Waas, president, Woman's Auxiliary to the Minnesota State Medical Association, presided at the meeting. Mrs. Roger S. Countryman was chairman.

BLUE EARTH COUNTY AUXILIARY HELPS SPONSOR HEALTH DAY

Mankato's second Health Day, held October 11, was a "Community Mental Health Day," sponsored by the Blue Earth County Medical Society and Auxiliary, Blue Earth-Nicollet Counties' Citizens' Mental Health Committee, District Health Unit No. 2 of the Minnesota Department of Health, Mankato State Teachers College, and the Mankato Branch, American Association of University Women.

Dr. H. J. Nilson, councilor of the Fourth District, Minnesota State Medical Association, presided during the afternoon session.

Outlines State Program

Minnesota's Mental Health Program was outlined by Dr. Ralph Rossen, commissioner of mental health, and Justin Reese, acting secretary, Minnesota Mental Health Council. Two films were shown: "Life With Junior" and "Preface to a Life." The afternoon session concluded with the panel discussion, "The Emotional Development of the Child," Dr. William S. Chalgren, Mankato neurologist and psychiatrist, moderating; Mrs. J. E. Wettleson and Dr. Harry R. Meyering, both of Mankato Teachers College; Rev. Charles L. Duxbury, pastor, First Christian Church, Mankato; Emil M. Meurer, juvenile probation officer, Blue Earth, Nicollet and Le Sueur counties; participating.

How Parents React

Dr. A. A. Schmitz, president, Blue Earth County Medical Society, presided at the evening meeting. Dr. Roger W. Howell, associate professor of neuropsychiatry, University of Minnesota, talked on "Parents' Reactions to Their Children."

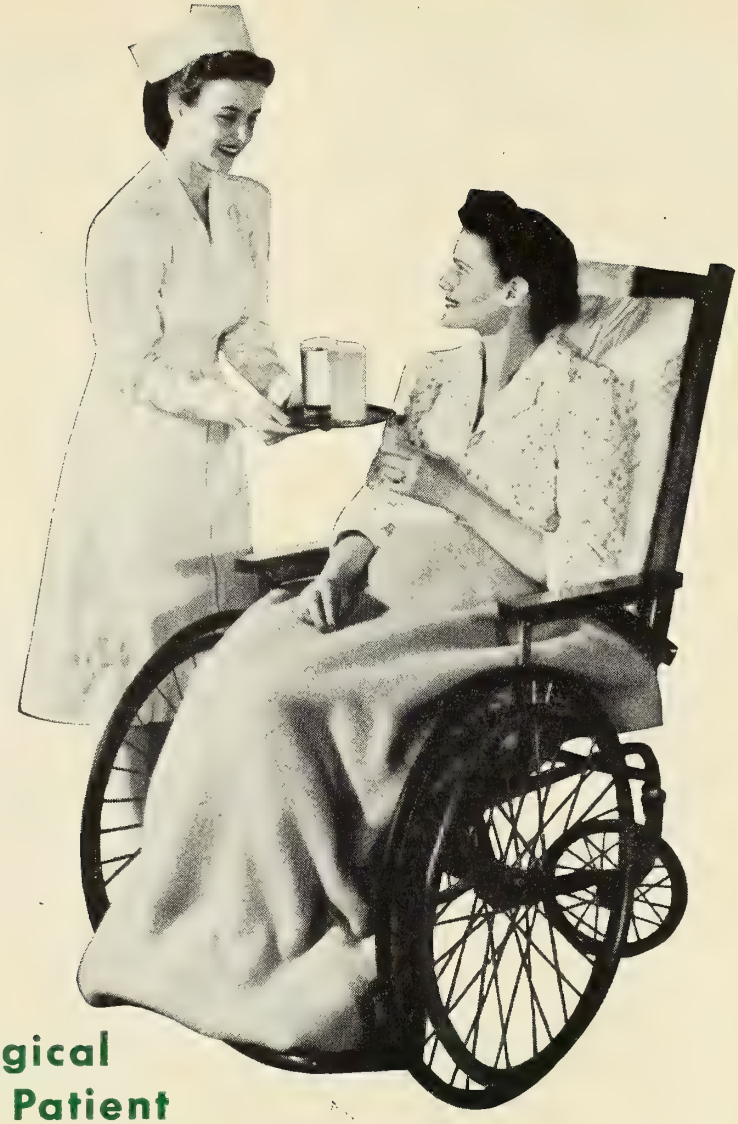
Dr. A. G. Liedloff, medical director of District Health Unit No. 2, Minnesota Department of Health, was general chairman. Miss Alberta Marshall of the A.A.U.W. and Mrs. W. B. Kaufman were co-chairmen of general arrangements with a committee made up of members of the medical auxiliary and Citizens Mental Health Committee.

A MESSAGE FROM THE CHAIRMAN

Mrs. Benjamin B. Souster

This year, as in the past, the editors of MINNESOTA MEDICINE are being most generous in the space given us for Auxiliary news. For the continued interest of readers, the Woman's Auxiliary to the Minnesota State

(Continued on Page 1146)



Constipation in the Postsurgical or Bedridden Patient

The combined effects of enforced inactivity, poor appetite and dietary restrictions frequently result in bowel sluggishness.

By adding bland "smoothage" and assuring a normal fecal consistency and volume, Metamucil gently initiates reflex peristalsis and encourages a return of normal bowel function.

METAMUCIL® is the highly refined mucilloid of Plantago ovata (50%), a seed of the psyllium group, combined with dextrose (50%) as a dispersing agent. G. D. Searle & Co., Chicago 80, Illinois.

RESEARCH IN THE SERVICE OF MEDICINE **SEARLE**

◆ Reports and Announcements ◆

MINNESOTA SOCIETY OF NEUROLOGY AND PSYCHIATRY

The regular meeting of the Minnesota Society of Neurology and Psychiatry was held at the Town and Country Club, Saint Paul, on November 14. The scientific program consisted of the presentation of the following papers: "Treatment of Subarachnoid Hemorrhages and Aneurysms" by Dr. Paul S. Blake, Hopkins, and Dr. Lyle A. French, Minneapolis; "Clinical Application of the Electroencephalogram" by Dr. V. Richard Zarling, Minneapolis.

CONTINUATION COURSES

Clinical Chemistry.—The University of Minnesota announces a continuation course in clinical chemistry for internists, pediatricians, and general physicians, December 7 to 9. Dr. John T. Merrill of Boston, Massachusetts, will be the visiting faculty member for the course.

Obstetrics.—A continuation course in obstetrics will be presented at the University of Minnesota on December 15 and 16. The course is intended for general physicians. Visiting faculty members for the course will include Dr. Emil G. Holmstrom, University of Utah Medical School,, Salt Lake City, Utah; Dr. Curtis J. Lund, Louisiana State University Medical School, New Orleans, Louisiana, and Dr. Charles E. McLennan, Stanford University Medical School, San Francisco, California.

Geriatrics.—The University of Minnesota announces a continuation course in geriatrics for internists and general physicians January 4 to 6. Distinguished visiting physicians who will participate as faculty members for the course include Dr. E. V. Cowdry, St. Louis, Missouri; Dr. William Dock, Brooklyn, New York; Dr. Nathan Shock, Bethesda, Maryland; Dr. E. J. Stieglitz, Washington, D. C., and Dr. E. L. Tuohy, Duluth, Minnesota.

Clinical Neurology.—Distinguished physicians who will participate as faculty members in a continuation course in clinical neurology to be presented by the University of Minnesota at the Center for Continuation Study from January 29 to February 10 are as follows: Dr. Pearce Bailey, Georgetown University School of Medicine, Washington, D. C.; Dr. H. W. Magoun, University of California Medical School; Dr. Henry Schwartz, Washington University School of Medicine, St. Louis, and Dr. S. Bernard Wortis, New York University Medical Center. Dr. Magoun will also deliver the annual J. B. Johnston lecture on the subject, "Wakefulness and Sleep."

PARKINSON'S DISEASE FOUNDATION

Plans of the newly organized Parkinson's Disease Foundation, with national headquarters at 744 Broad Street, Newark, N. J., were recently announced. Officials stated that plans are being made for setting up units of the Foundation in the major cities of the United States, to provide treatment for persons afflicted with the disease, of whom there are estimated to be one million sufferers.

Medical advisors for the Foundation include Dr. John C. Button, Jr., medical director of the Button Neurological Institute, Orange, N. J., Dr. Thomas Meyers of the Meyers Clinic, and Dr. K. G. Bailey, neurosurgeon of the Los Angeles County Hospital, both of Los Angeles, California.

RICE COUNTY SOCIETY

Dr. J. J. Kolars, Faribault, was elected secretary-treasurer of the Rice County Medical Society at a meeting held in Faribault on September 26. The post of secretary-treasurer was the only office for which an election was held.

The principal topic for discussion at the meeting was the problem of civil defense in the area. Dr. C. W. Rumpf, Faribault, was the principal speaker and moderator in the discussion.

STEARNS-BENTON COUNTY SOCIETY

At the October meeting of the Stearns-Benton County Medical Society, Dr. Gordon R. Kamman, Saint Paul, presented a talk on "Psychosomatic Medicine."

Dr. Reuben F. Erickson, Minneapolis, chairman of the Policy Committee of the Minnesota State Medical Association, was also a guest speaker at the meeting.

WABASHA COUNTY SOCIETY

The eighty-second annual meeting of the Wabasha County Medical Society was held at Wabasha on October 5.

During the afternoon business session officers were elected to serve as follows: Dr. William P. Gjerde, Lake City, president; Dr. Doreen A. Martin, Wabasha, vice president; Dr. W. F. Wilson, Lake City, secretary, and Dr. B. A. Flesche, Lake City, assistant to the secretary. The society members also discussed and endorsed participation in the current educational campaigns and public health programs.

Preceding the evening scientific session, Dr. A. J. Chesley, executive officer of the Minnesota State Board of Health, discussed medical preparedness in civil defense.

The scientific session consisted of the following presentations: President's Address, "Acute Pancreatitis" by the retiring president, Dr. L. M. Ekstrand, Wabasha; "A Review of the More Common Neurologic Disorders" by Dr. L. M. Eaton, Rochester; a color motion picture, "An Improved Technique for the Operative Treatment of Common Anorectal Lesions."

Thirty-two persons attended the dinner held between the business and scientific sessions. During the evening the ladies attending were entertained at the home of Dr. and Mrs. Ekstrand.

WRIGHT COUNTY SOCIETY

Dr. W. E. Hall, Maple Lake, was elected president of the Wright County Medical Society at its meeting at Buffalo on October 10. Also named to office were Dr. Waldo Anderson, vice president, and Dr. Theodore Catlin, secretary-treasurer, both of Buffalo.

Now Available . . . .

Complete, modern facilities of the Glenwood Hills Hospitals; co-ordinated to give an accurate diagnosis and proper treatment to the neuropsychiatric patient.

These unique facilities include:

- An Outstanding staff of neurologists and psychiatrists
- Electroencephalography
- Electrocardiography
- An ultra-modern laboratory
- A completely equipped x-ray room
- Occupational therapy and Hydrotherapy
- A new physical education department
- Nurses specially trained in our own neuropsychiatric training school

Enroll now for School of Psychiatric Nursing. Prospective candidates should apply and register immediately.

One year course—tuition free

In Memoriam

OTIS O. BENSON, SR.

Dr. Otis O. Benson, Sr., eighty-three, of Willmar, Minnesota, died in Minneapolis on October 16 following a protracted illness. Uremia was given as the immediate cause of his death. Funeral services were conducted in Minneapolis on October 19 with final interment at Jeffersonville, Ohio.

Dr. Benson was born in 1867 at Jeffersonville. He took his B.A. degree from Ohio Northern University at Ada, Ohio. He also graduated from the University of Iowa in 1898, and from Rush Medical College in 1902. A life-long member of the American Medical Association, he retired in 1947 after more than forty-five years practice.

He is survived by two children: Brig. Gen. Otis O. Benson, Jr., Commandant of the U. S. Air Force School of Aviation Medicine, Randolph AFB, Texas, and Mrs. L. A. Utrecht of South Charleston, Ohio.

NIMROD A. JOHNSON

Dr. Nimrod A. Johnson, a surgeon in Minneapolis prior to his retirement in 1936, died at his home in Santa Monica, California, September 6, 1950, following a cerebral hemorrhage.

Dr. Johnson was born in Saint Paul, October 1, 1880. He graduated from the University of Minnesota medical school in 1905, and interned at Swedish Hospital, Minneapolis. He practiced general surgery in Minneapolis and with his brother, Dr. Norton T. Johnson, founded the Bloomington-Lake Clinic.

Dr. Johnson was an affiliate member of the Hennepin County Medical Society, the Minnesota State Medical Association, the American Medical Association and the American College of Surgeons. He was also a Mason and a member of the Scottish Rite and Zuhrah Temple of the Shrine.

Besides his brother, Dr. Johnson is survived by his wife, Florence, and two daughters, Mrs. Clifford F. Traff, Minnetonka Beach, and Mrs. Jerome Hiniker, Falls Church, Virginia.

WOMAN'S AUXILIARY

(Continued from Page 1142)

Medical association is eager to hear from every county in the state.

Articles on newly organized Auxiliaries and plans for the coming year will be greatly appreciated, as well as information about local meetings, programs and Health Days. These may be sent to Mrs. B. B. Souster, 1333 Bohland Place, Saint Paul 5, Minnesota. Personal news items may be sent to the chairman of the Newsletter, Mrs. L. S. Arling, 2310 E. 43rd St., Minneapolis, Minnesota.

✦ Of General Interest ✦

Dr. Philip S. Hench and **Dr. Edward C. Kendall,** of the Mayo Clinic, and **Dr. Jadeusz Reichstein,** of the University of Basel, have been awarded the Nobel Prize in medicine for 1950. The prize money, amounting to 164,303 crowns ($31,715), will be divided between the three doctors and presented to them at Stockholm on December 10. It was Dr. Kendall who discovered cortisone about ten years ago and Dr. Hench who applied it clinically in the treatment of rheumatoid arthritis. Dr. Reichstein shared in the development of the chemistry of the extracts.

* * *

Word has been received that **Dr. Alexander M. Boysen,** a graduate of the University of Minnesota Medical School in 1948, was reported on July 12 as missing in action in Korea. Six weeks later notification was received by his wife that Dr. Boysen was being held as a prisoner of war.

A native of Minnesota, Dr. Boysen served his internship at St. Francis Hospital, Pittsburgh, Pennsylvania. He then accepted a three-year Army clinical residency and was assigned to Madigan General Hospital at Fort Lewis, Washington. He was sent to Yokohama, Japan, in May of 1950 for ninety days of temporary duty. While there he was assigned to the 24th Infantry Division and sent to Korea. At the time of his capture by the North Koreans he held the rank of captain in the medical corps.

* * *

On October 4, **Dr. John F. Madden,** Saint Paul, spoke before the permanent and consulting staffs of the Veterans Hospital at Lincoln, Nebraska, on the subject, "Cutaneous Manifestations of Internal Diseases."

* * *

Dr. C. G. Uhley, Crookston, spoke on a radio program entitled "Cancer on Trial," which was presented over station KROX, Crookston, on September 20. Dr. Uhley is the local chairman for the Minnesota Division of the American Cancer Society.

* * *

Dr. William F. Braasch of Rochester was named president of the Minnesota Public Health Association at its annual meeting in Coffman Memorial Union, October 24. He succeeds Edward A. Knapp, Saint Paul attorney, who has been president for several years.

* * *

Dr. John M. Fallon of Wooster, Massachusetts, was elected president of the **Mayo Foundation Alumni Association** at the annual meeting on October 20. Other officers elected were Dr. John L. Kleinhechsl, Wichita, Kansas, first vice president; Dr. Nat H. Copenhaver, Bristol, Tennessee, second vice president; Dr. James F. Weir, Rochester, secretary, and Dr. Edward S. Judd, Rochester, associate secretary and treasurer.

Dr. Thomas J. Kinsella, Minneapolis, is retiring president.

* * *

Six nurses with many years of service to the cause of tuberculosis were honored with a dinner in Coffman Memorial Union on October 24. Two Saint Paul nurses are Sibba Axford, chief nurse at Mineral Springs Sanatorium at Cannon Falls from 1924 to 1948 and who is now a supervisor at St. Luke's hospital in Saint Paul, and Margaret Weikert, resident director of the Ramsey County Childrens Preventorium and a staff member there for thirty-three years. The four others are: Mrs. Sue T. Naysmith, head of the department of nursing at Glen Lake Sanatorium from 1920 until her retirement in 1941; Mathilda Hallberg, who is now employed at Southwestern Minnesota Sanatorium in Worthington; Alice Sorenson, chief nurse at Granite Falls; and Lulu Healy, who was chief nurse at Minnesota State Sanatorium, Ah-Gwah Ching, from 1917 until 1940.

More than 200 Christmas seal workers from all Minnesota counties attended the dinner and were addressed by Leigh Mitchell Hodges, Philadelphia columnist and one of the founders of the Christmas seal campaign. Dr. E. M. Hammes, Sr., presided at the meeting which was in connection with a course in tuberculosis control for lay persons given at the University.

* * *

Dr. Dewey E. Moorehead of Owatonna was elected grand high priest of the Minnesota Royal Arch Masons at the annual meeting of the organization in Saint Paul on October 10.

* * *

Dr. Lloyd S. Nelson, Minneapolis, spoke on "Rheumatic Fever in Children, with Special Emphasis on the Differential Diagnosis" at a meeting of the Lyon-Lincoln County Medical Society at Marshall on October 10, The meeting was part of the forty-second semi-annual clinic course sponsored by the society.

* * *

Dr. Carl J. Lind, formerly of Minneapolis, has been promoted from lieutenant colonel to colonel at the Brooke Army Medical Center, Fort Sam Houston, Texas, where he is chief of the laboratory service. A graduate of the University of Minnesota Medical School, Dr. Lind took four years of postgraduate work in surgery and roentgenology at the university. He also specialized in pathology.

tended meetings of the Central Obstetrical and Gynecological Society at Milwaukee and at Chicago. He also attended a three-day conference at the University of Minnesota Center for Continuation Study.

* * *

September 16 was Dr. Farrish Day at Sherburn. On that day **Dr. Robert C. Farrish,** who has completed fifty years of medical practice, celebrated his eighty-third birthday and received congratulatory messages from his friends. The day was proclaimed in his honor by the mayor of Sherburn.

* * *

Dr. John J. Bittner, director of cancer biology at the University of Minnesota and George Chase Christian professor of cancer research, was presented with the second annual Minnesota award of the American Cancer Society at a dinner in Coffman Memorial Union on September 22.

* * *

Technicians, nurses, bookkeepers, secretaries and receptionists employed by members of the Hennepin County Medical Society have organized a new group, the **Medical Assistants of Hennepin County.** First president of the organization is Dorothy Reid. Civil defense volunteer work with the Red Cross is one of the first projects of the group.

* * *

Dr. Russell J. Moe, Duluth, became president of the Central Association of Obstetricians and Gynecologists at its annual meeting in Milwaukee late in September. Dr. Moe was named president-elect at the 1949 meeting of the group in St. Louis. He has been a member of the executive committee since 1941.

* * *

Late in September **Dr. Chester J. Olson** moved his office and residence into his newly constructed, combination office-and-home building in Belle Plaine. The modern structure contains twelve rooms, six used for the office and six for living quarters. The entire building is heated by a radiant heating system.

* * *

The private duty nurses of the **Minnesota Nurses Association** decided at their meeting held in the Nicollet Hotel, Minneapolis, in October, to raise their rates, effective in the near future. The fee for the eight-hour periods from 7 a.m. to 3 p.m. and 11 p.m. to 7 a.m. will be increased from $10 to $12, and the shift from 3 p.m. to 11 p.m., from $11 to $13. They also decided that when more than one patient is being nursed the rate will be $16 for the shifts of 7 a.m. to 3 p.m. and 11 p.m. to 7 a.m., and $17 for the 3 p.m. to 11 p.m. shift. Also, types of nursing which formerly required an additional dollar, such as the nursing care of a mother and baby, tuberculosis patients and those with contagious diseases, drug addicts, alcoholics and mentally ill now will require two dollars additional.

* * *

Dr. Harold S. Diehl, dean of medical sciences at the University of Minnesota, was appointed by the

A DISTINGUISHED BAG

with a *Distinguishing* feature

"OPN-FLAP"

HYGEIA
MEDICAL BAGS

. . . *it holds ⅓ more!*

The famous patented "OPN-FLAP" feature, designed with the advice of physicians, permits opening of Hygeia Bag to the full length and width of top, thus allowing ⅓ more space for packing. Hygeia is the only medical bag that can be packed to the very top and easily zipped closed without crushing or jamming the contents. Made of the finest top grain leathers by luggage craftsmen, the "OPN-FLAP" Hygeia Medical Bag is preferred by doctors everywhere.

Municipal Bonds and Inflation

Perhaps the most common problem confronting an investor today concerns the problem of inflation and its eventual effect upon his savings. Mr. Phillips Barbour, Editor of the Bond Buyer, addressed the Municipal Forum of the National Security Traders Association recently on this problem—the quotations below are from this address:

> "No sure way to avoid the ravages of inflation, if present, has yet been discovered. Our discussion today is not intended to find a cure for the malady, however, but to point out some of the reasons municipal bonds, in my opinion, will aid the American investor greatly in maintaining an investment portfolio in as healthy a condition as is possible in the present inflation and why he should not put all his eggs in the equity basket.
>
> "Investments of many kinds have been suggested as suitable in these circumstances . . . none supplies the perfect solution in practice. The more popular suggestions include real estate, farm lands, growing trees, aging liquor, breeding live stock, jewels and precious stones, works of art and, of course, commodities and common stocks or equities.
>
> "The ideal investment, under present conditions, is one which provides:
>
> (1) Safety of principal—that is the most important requisite.
>
> (2) Dependability of income—the larger the better, but regardless of size, it should be dependable.
>
> (3) Opportunity for growth—in both principal and interest.
>
> (4) It must be realistic. There is a limit to the number of investors who can breed cattle, for instance.
>
> "Obviously, the majority of the suggestions I have mentioned do not fit entirely satisfactorily into the pattern of requirements specified. Where they may possess one good feature, they are deficient in others.
>
> "Even after determining the category to be used, the problem of choosing the particular unit, or units, to be bought is often the block over which the buyer stumbles. A decision must be made as to the particular farm, commodity, work of art, or stock, which should be bought after the die is cast, as to the category which is practicable for the investor to employ. All oil stocks don't invariably go up or all real estate always improve in value."

That portion of Mr. Barbour's address showing how municipal securities meet the requirements of the ideal investment outlined above, will appear in the next article.

We have reprints of Mr. Barbour's address available and will be pleased to send you one. without obligation, upon request.

President on October 4 to a seven-member commission to advise Selective Service on the drafting of physicians and dentists for the armed forces. The commission is headed by Dr. Howard Rusk, physician-writer for the *New York Times*.

* * *

Dr. Russell O. Sather, Crookston, presented one of the panel discussions on practical problems of health officers at a meeting of Minnesota health officers in Minneapolis on September 25. Dr. Sather's topic was "Small Town Housing."

* * *

Excavation for construction of a new office building in North Saint Paul began late in September. When completed, the building will house the offices of **Dr. A. E. Muller** of North Saint Paul.

* * *

The city council of Biwabik on October 2 accepted the resignation of **Dr. R. B. Bray** as health officer and approved the hiring of **Dr. S. C. Blackmore** as health officer. Dr. Bray's resignation followed his announcement that he had sold his hospital and was moving to Rapid City, South Dakota (see Hospital News).

* * *

This year, as in previous years, the **Ramsey County Medical Society**, not content to let the Community Chest campaign alone, sent letters to all members of the society, urging them to contribute generously to the Community Chest. In addition, a special committee of the society organized speeches by campaign leaders to the medical staffs of the city's hospitals. Such direct solicitation by the medical society, it was announced, has raised the percentage of participation of doctors in Saint Paul to 86, in contrast to a 64 per cent average in thirty-one selected cities.

* * *

It was announced on September 14 that **Dr. George L. Stuhler** had become associated in practice with Dr. N. T. Norris of Caledonia. Dr. Stuhler, it was stated, would remain in Caledonia until the time arrives for him to begin his fellowship at the Mayo Clinic. A graduate of the University of Minnesota Medical School, he served his internship at the Detroit Receiving Hospital.

* * *

Dr. Frederick L. Behling, Oklee, attended a short course in diseases of children at the Children's Memorial Hospital in Chicago during the middle of September.

* * *

Dr. William S. Chalgren, Mankato, was the principal speaker at a meeting of the fifth district of the Minnesota Nurses' Association in Mankato on September 11. Dr. Chalgren's topic was "Mental Mechanism."

* * *

Appointment of **Dr. Charles W. Mayo,** Rochester, to the board of judges for the annual Dr. C. C. Criss award was announced on October 25 by the Mutual Benefit Health and Accident Association of Omaha, Nebraska. The award, named for the founder of the firm, consists of $10,000 and a gold medal and goes to the individual who, in the judges' opinion, has made the greatest contribution to public health and/or safety during the year.

* * *

Dr. Lloyd C. Gilman, Willmar, left for Chicago on October 9 to take a two-week postgraduate course in fractures at the Cook County Hospital.

* * *

Sanborn lost its only physician on October 21 when **Dr. Aldridge F. Johnson** moved to Indianapolis to become assistant superintendent of the Sunnyside Tuberculosis Sanitorium there. Dr. Johnson, who formerly was on the staff of the state sanitorium at Roseau, practiced at Sanborn for almost two years.

* * *

Dr. A. J. Chesley, director of the Minnesota Health Department, and his assistant, **Dr. Robert Barr,** attended the United States Public Health Service Conference in Washington, D. C., October 23 through 27. Medical aspects of civil defense were discussed at the conference.

* * *

An address by **Dr. John E. Haavik,** Duluth, was a feature of a meeting of the Duluth Multiple Sclerosis Club on September 19.

* * *

Dr. Karl R. Lundeberg, former resident of Minneapolis and a graduate of the University of Minnesota Medical School, has been named director of preventive medicine at the Army's medical field service school, Fort Sam Houston, Texas.

* * *

The **Mayo Clinic emeritus staff** now numbers thirty-one members, seven of whom no longer live in Rochester.

* * *

Construction has been completed on the new office building of **Dr. E. E. Zemke** and **Dr. William Misbach** in Fairmont. The modern-designed structure houses two consultation rooms, four examining rooms, laboratory, first aid room, pediatric room, rooms for x-ray and other diagnostic apparatus, and an office suite for a dentist.

* * *

Both the Hennepin County and Ramsey County Medical Societies now offer a **telephone answering service** to enable the public to obtain immediate medical attention at any hour of the day or night. The service is designed to aid persons who cannot reach their own physician—or do not have one—when a medical emergency arises. The service is especially valuable to persons who have recently moved to Minneapolis or Saint Paul and who do not know a physician.

The telephone number of the service in Saint Paul, conducted by the Ramsey County Medical Society,

If You Are Called Into Service—
If You Are Too Old to Be Called Into Service—

In either event the rebellion in Korea affects your pocketbook in a major way, which will be reflected in your accounts receivable.

Soldiers Relief from their financial obligations has again been invoked making it impossible to enforce collection against anyone in the Armed Forces.

With our many years of valuable experience in handling the accounts for over 1,000 professional men, there is now an influx of professional accounts to this office due from patients about to enter Military Service where the possibility of immediate collection appears very problematical.

Our Recommendations

Based upon our experience in liquidation of accounts prior to, during, and after World War II

(1) Concentrate effort on the collection of accounts against patients who may be called in the Armed Forces.

(2) THE TIME TO COLLECT IS NOW because with inevitable continued inflation, increased salaries and wages, farm prices, commodity prices, there will be more money in circulation.

(3) That if you already have been called into the service or anticipate being called that you permit this qualified organization to act as your liquidating agent.

Our many years of experience handling accounts in the professional field plus our contractual relationship with fifty trade associations extending from coast to coast, proves we are rendering outstanding service.

Professional, commercial trade associations, and bank recommendations furnished.

is CEdar 5751. The number of the Minneapolis exchange, operated by the Hennepin County Medical Society, is FIllmore 1411.

Any patient who is cared for by a physician on one of these emergency calls is billed only by the individual physician. There is no charge for the special telephone service, which is offered to each community as a public service by the members of the two medical societies.

* * *

Dr. A. G. Sanderson has resigned as superintendent of the Deerwood Sanatorium and has accepted a position on the staff of the Anoka State Hospital.

* * *

Dr. Raymond C. Magnuson and Miss Janet Joyce Widen, daughter of Dr. W. F. Widen of Minneapolis, were married in Minneapolis on September 16. They are now living in Cambridge. Dr. Magnuson is a graduate of the University of Minnesota Medical School.

* * *

Dr. F. Lionel Pickett, a general practitioner in England, was guest speaker at a meeting of the Kiwanis Club in Duluth on September 13. He stated that he disliked the British medical plane "intensely," and he pointed out that the program is defective because: (1) it will probably ruin England financially since it already operates at a loss of $900,000,000 annually; (2) the health of British people is deteriorating under the plan; (3) specialists have a far too heavy patient load and are being forced to become general practitioners.

* * *

Dr. Curtis M. Johnson, formerly of Jackson, has become affiliated in practice with Dr. M. I. Hauge at the Clarkfield Clinic.

* * *

A law providing for vitamin and mineral enrichment of all bread offered for public sale was urged by **Dr. Russell M. Wilder,** Rochester, at a meeting of the American Bakers Association in Chicago on October 17. Dr. Wilder said that the dietary qualities of enriched bread should be improved through the use of more non-fat milk solids.

* * *

Dr. Walter H. Judd, Representative from Minnesota's Fifth District, was a featured speaker at the third annual Workshop of the Woman's Auxiliary to the Minnesota State Medical Association in Saint Paul on October 16. The title of his talk was "A Prescription for a Healthy Government."

* * *

Four Rochester physicians were guest speakers at the fifteenth annual assembly of the United States Chapter, International College of Surgeons, in Cleveland from October 31 to November 3. The four speakers were Dr. Virgil S. Counseller, Dr. Stuart W. Harrington, Dr. John S. Lundy, and Dr. Gershom J. Thompson. President-elect of the organization is Dr. Henry W. Meyerding of Rochester.

* * *

Before **Dr. Edwin Rose,** chief medical officer of the Minneapolis Veterans Hospital, was transferred to the Washington office of the Veterans Administration, he was honored at a dinner in Minneapolis on October 18 given by members of the Minneapolis chapter of the Disabled American Veterans.

* * *

Dr. Ralph J. Gampell, former British physician, discussed socialized medicine under bureaucratic control at a meeting of the Saint Paul Association of Commerce on October 20. Dr. Gampell, who left England in April, 1949, "to find freedom in medicine as well as freedom as an individual," as he states, spoke under the auspices of the national education campaign of the AMA. He is now a resident of San Francisco, where he recently completed an internship and was licensed to practice.

* * *

Almost immediately after moving to Bagley to be associated in practice with Dr. L. J. Larson, **Dr. George Miners** left for North Carolina in September to complete a ten-week course for a degree for which he had been working. Following completion of the course, he expects to return to Bagley to begin permanent practice.

His colleague, **Dr. L. J. Larson** of Bagley, was honored for his twenty-five years of service in the community at a banquet given by the Bagley Civic and Commerce Association on September 12. Dr. K. W. Covey, Mahnomen, was the principal speaker at the banquet.

* * *

Dr. O. K. Behr, Crookston, discussed the subject, "Know Your Heart," on a radio broadcast over station KROX, Crookston, on October 18.

* * *

A cancer teaching clinic for members of the medical profession from Minnesota and Wisconsin was held in Duluth on October 18. The principal speaker at the meeting was **Dr. Alexander Brunschwig,** professor of clinical surgery at Cornell University Medical College, who spoke on "Radical Surgery in Advanced Cancer of the Female Genital Tract." The clinic was sponsored by medical societies of Minnesota and Wisconsin and by the state health departments and the state divisions of the American Cancer Society.

* * *

Dr. Edwin G. Knight, Swanville, who was injured in an automobile accident on September 1, returned to his home on September 17, expecting to be back in his office on a limited basis within a short time. It was expected, however, that a few weeks would pass before his fractured right arm would heal sufficiently to enable him to assume his full duties.

An Observation on the Accuracy of Digitalis Doses

Withering made this penetrating observation in his classic monograph on digitalis: "The more I saw of the great powers of this plant, the more it seemed necessary to bring the doses of it to the greatest possible accuracy."[1]

To achieve the greatest accuracy in dosage and at the same time to preserve the full activity of the leaf, the total cardioactive principles must be isolated from the plant in pure crystalline form so that doses can be based on the actual weight of the active constituents. This is, in fact, the method by which Digilanid® is made.

Digilanid contains all the *initial* glycosides from Digitalis lanata in crystalline form. It thus truly represents "the great powers of the plant" and brings "the doses of it to the greatest possible accuracy".

Clinical investigation has proved that Digilanid is "an effective cardioactive preparation, which has the advantages of purity, stability and accuracy as to dosage and therapeutic effect."[2]

Average dose for initiating treatment: 2 to 4 tablets of Digilanid daily until the desired therapeutic level is reached.
Average maintenance dose: 1 tablet daily.
Also available: Drops, Ampuls and Suppositories.

1. *Withering, W.:* An account of the Foxglove, London, 1785.
2. *Rimmerman, A. B.:* Digilanid and the Therapy of Congestive Heart Disease, Am. J. M. Sc. *209:* 33-41 (Jan.) 1945.

Literature giving further details about Digilanid and Physician's Trial Supply are available on request.

Dr. Viktor O. Wilson, health officer of the Rochester-Olmsted County Public Health Unit, was elected president of the Minnesota Public Health Conference in Minneapolis on September 25 and 26. He succeeds Dr. F. W. Behmler of Morris.

* * *

Dr. Kenneth L. Buresh, formerly of Baxter, Iowa, moved to Westbrook early in September and began practice. He and Dr. John V. Carlson, the only other physician in Westbrook, are occupying new offices in a recently remodeled building in the city. Dr. Buresh is a graduate of the University of Iowa.

* * *

Forty-three years of medical practice in Detroit Lakes were ended late in October when **Dr. James E. Carman** closed his offices and moved to Glendale, California. A graduate of the University of Minnesota Medical School, Dr. Carman began his Detroit Lakes practice in 1907, a few years after his graduation.

* * *

The week of November 12 to 18 was designated as **Diabetes Detection Week,** during which the American Diabetes Association and its affiliates conducted the annual diabetes detection drive with the co-operation of the nation's physicians. All persons were asked to go to their own physicians for free diabetic examinations. In many cities arrangements were made with the city health department to examine urine specimens, and drug stores were designated as collection depots for the specimens. By such methods members of the national organization expected to discover about a million persons throughout the country who have diabetes without knowing it.

* * *

More than 200 guests attended an open house given for **Dr. Gustave L. Rudell,** Minneapolis, in honor of his seventy-fifth birthday on September 24. Born in Sweden, Dr. Rudell came to America in 1892 and attended the University of Minnesota Medical School. He is still actively engaged in his medical practice.

HOSPITAL NEWS

It was announced in Biwabik late in September that the **Biwabik Hospital** had been sold by Dr. Robert B. Bray to Dr. Sidney C. Blackmore. Dr. Blackmore, who has been associated in practice with Dr. Bray for the past five years, said that the operation of the hospital would continue in the same manner as in the past.

Dr. Bray, who has been owner and manager of the hospital for the past thirteen years, since the death of his father, the late Dr. C. W. Bray, planned to remain in Biwabik until an assistant could be found for Dr. Blackmore. He then planned to move to Rapid City, South Dakota.

The hospital, one of the first to be built on the Mesabi Range, was originally constructed about

An organizational meeting of the medical staff of the new **Wells Hospital** was held in Wells on October 5. Officers were elected as follows: Dr. Richard P. Virnig, chief of staff; Dr. William H. Barr, vice president, and Dr. Mark P. Virnig, secretary-treasurer, all of Wells.

BLUE CROSS-BLUE SHIELD NEWS

Enrollment in Minnesota Medical Service, Inc., as of August 31, 1950, was 372,187, an increase of 111,686 to date this year. Blue Cross enrollment as of the same date totaled 1,029,718 participant subscribers.

Payments to doctors for the month of August totaled $193,848 or 66.8 per cent of cash earned income and to date this year payments total $1,321,836 or 71 per cent of the cash earned income compared with $676,694 or 73.8 per cent for the same period last year. Blue Shield claims for the month of August totaled 4,911 and provided payment for 5,877 medical-surgical services, an increase of 299 claims or 405 services over the July payment. The total amount paid during the month amounted to $193,847.65, an increase of $20,544.33 over the month of July. The first eight months of 1950 Blue Shield claims totaled 33,358 cases in the amount of $1,321,836.17.

Payments to unlimited subscribers amounted to 28.3 per cent of the total payments to doctors during August. The payments to doctors for unlimited subscriber claims paid during the first eight months of 1950 totaled $391,443.52 or 29.6 per cent of the total payments compared with 19.3 per cent during the same period of 1949.

During the month of August payment was made for 466 tonsillectomies. The number of surgical services paid during the month increased from 3,123 or 57.1 per cent in July to 3,285 or 55.9 per cent in August. 3,776 claims or 76.9 per cent of the total paid were incurred in hospitals during August compared with 77.1 per cent during July. Payments for these hospitalized cases totaled $176,850.15 compared with the July total of $158,448.07. Claims for services rendered in doctor's offices totaled 1,121 or 22.8 per cent of total compared with 22.3 per cent during July.

On the year to date figures we show that 32,015 claims have been paid to participating doctors in a total amount of $1,258,173.37 with 652 claims being paid to non-participating doctors in the amount of $33,864.08 and 691 claims in the amount of $29,798.72 being paid to out-of-state doctors.

RELIABILITY!

BOOK REVIEWS

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical Libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

PRINCIPLES AND PRACTICE OF SURGERY. Jacob K. Berman, A.B., M.D., F.A.C.S., Associate Professor of Surgery, Indiana University School of Medicine; Associate Professor of Oral Surgery, Indiana University School of Dentistry; Chief Consultant in Surgery, Billing's Veterans Administration Hospital, Fort Benjamin Harrison, Indiana; Director of Surgical Education and Surgical Research, Indianapolis General Hospital. 1378 pages. Illus. Price $15.00, cloth. St. Louis: C. V. Mosby Co., 1950.

PROGRESS IN GYNECOLOGY. Volume II. Edited by Joe V. Meigs, M.D., Clinical Professor of Gynecology, Harvard Medical School; Chief of Staff of Vincent Memorial Hospital, the Gynecological Service of the Massachusetts General Hospital; Surgeon, Pondville Hospital; Gynecologist, Pamer Memorial Hospital; and Somers H. Sturgis, M.D., Clinical Associate in Gynecology, Harvard Medical School; Assistant Surgeon, Massachusetts General Hospital, Boston. 821 pages. Illus. Price $9.50, cloth. New York: Grune & Stratton, 1950.

MANAGEMENT OF OBSTETRIC DIFFICULTIES. Fourth Edition. Paul Titus, M.D. Obstetrician and Gynecologist to St. Margaret Memorial Hospital, Pittsburgh; Consulting Obstetrician and Gynecologist to the Shadyside Hospital, Pittsburgh; Secretary of the American Board of Obstetrics and Gynecology; Member Reserve Consultants Advisory Board, Bureau of Medicine and Surgery, United States Navy (Captain, MC, USNR). 1046 pages. Illus. Price $14.00, cloth. St. Louis: C. V. Mosby Co., 1950.

OSLER APHORISMS, From His Bedside Teachings and Writings. Collected by Robert Bennett Bean, M.D.; edited by William Bennett Bean, M.D. 158 pages. Price $2.50, cloth, New York: Henry Shuman, Inc., 1950.

NATIONAL FORMULARY—Ninth Edition. 877 pages. Illus. Price $8.00 ($8.75 outside United States), cloth. Washington, D. C.: American Pharmaceutical Association, 1950.

THE ANTIHISTAMINES; THEIR CLINICAL APPLICATION, by Samuel M. Feinberg, M.D., Associate Professor of Medicine, Chief of Division of Allergy and Director of Allergy Research Laboratory; Saul Malkiel, Ph.D., M.D., Assistant Professor of Medicine, Director of Research, Allergy Research Laboratory; Alan R. Feinberg, M.D., Clinical Assistant in Medicine, Attending Physician in Allergy Clinic, Northwestern University Medical School. 291 pages. $4.00. Chicago: The Year Book Publishers, Inc., 1950.

"The Antihistamines" by Drs. S. M. Feinberg, S. Malkiel and A. R. Feinberg is a concisely written book covering the subject adequately. The monograph is divided essentially into two divisions. The first section deals with experimental studies in relation to histamine and antihistamines, while the second section deals with clinical observations as noted by the authors and other investigators. In the section dealing with experimental studies, the following subjects are covered sufficiently, but each topic is not delved into deeply: (a) Histamine and its role in allergy, (b) The chemistry of the antihistamines, (c) The pharmacology of the antihistamines, (d) The antihistamines in experimental hypersensitivities, and (e) The bioassay of antihistamines in man. In the section discussing the clinical observations the following factors and conditions are covered: (a) Respiratory allergy, (b) Dermatoses, (c) Miscellaneous medical manifestations, (d) Administrations and recommended dosage of the various drugs, (e) and The toxic effects of the commonly used antihistamines. Besides the two

main divisions in the book, there is a lengthy, complete (to date), useful appendix that lists all American-produced antihistamines (prescription, not over the counter packages) along with their accepted dosage, and the name of the pharmaceutical company that markets them. The bibliography lists 583 references which represents a good sampling of the over-abundant current and historical literature on the subjects discussed in the text.

The book itself is well-organized and follows a definite pattern; however, each chapter could be read independently without disrupting any continuity of thought. There is a tendency toward repetition in some of the clinical as well as the experimental chapters, and this might detract partially if one reads the book through from cover to cover. However, if one uses the book as a reference manual, this fault then becomes a benefit, as one is able to find a more complete scope of information by reading only the chapter in which he might be interested at the time.

This manuscript is one that is well worth having on any library shelf, but like so many books written on a subject that changes rapidly and progresses quickly, its clinical value is lost and outmoded soon after being released from the press, and it readily becomes a historical reference rather than a current digest.

Irvine M. Karon, M.D.

PARKINSON'S DISEASE. Advice and Aid for Sufferers of Parkinson's Disease and Other Physical Disabilities. By Walter Buchler. 75 pages. Price $1.00 and $2.00 cloth. Mr. Walter Buchler 101, Leeside Crescent, London, N. W. 11, England.

This little book is the author's account of his experiences as a patient with Parkinson's disease and his recommendations, advice, and philosophy arising therefrom. Most of the chapters are written in the second person. The book covers a wide range of subjects—aids in walking, care of the feet, manner of dress and style of clothing most suitable to the sufferer, diet, "table tactics" housing, furniture, planning for work, entertainment, and social events.

The information in this book is not new, but it reminds the physician that treating a patient with physical disability involves much more than drug therapy. The importance of management of the patient as a person is the primary consideration, and some helpful topics for consideration are found here. For the patient, this book offers some helpful hints as well as sympathetic insight into living with a disabling illness.

R.D.M.

PEPTIC ULCER. A. C. Ivy, M. I. Grossman, and W. H. Bachrach. 1144 pages. Price $14.00. Philadelphia and Toronto: The Blakiston Co., 1950.

Doctor Ivy and his associates have made an outstanding contribution to Medical Science in this volume. An enormous amount of material, summarizing the most significant experimental and clinical studies relating to gastric and duodenal ulcer, has been skillfully organized and well presented.

The volume is divided into four sections: Introduction to the Problem of Peptic Ulcer; Pathogenesis; Diagnosis, and Treatment.

Each chapter in the book is concluded with a summary, and each section is concluded with a summarizing chapter. This device adds much to the clarity of the presentation and assists the reader to a better understanding of the ulcer problem as a whole.

The authors, conversant as they are with the subject, are eminently qualified to present such a critical review. The value of the book is emphasized by Dr. A. J. Carlson who has said: "This is a *must* book, not only for our colleagues in general practice but also for our colleagues in internal medicine, surgery, psychiatry and physiology."

George S. Bergh, M.D.

OUT OF MY LIFE AND THOUGHT. Albert Schweitzer. New York: Henry Holt & Co., 1933 and 1949.

This autobiography of a remarkable theologian, musician and physician—all in one—first appeared in 1933 but attracted little attention. The 1949 printing of a revised volume with a postscript by Everett Skilling, close friend of Dr. Schweitzer and chairman of the Albert Schweitzer Fellowship, has had several printings.

Albert Schweitzer, an Alsatian, had already acquired distinction as a theologian, philosopher and musician when at the age of thirty he decided to study medicine after hearing of the great need for physicians in Lam-

barane, Africa. Against the advice of friends who argued he was throwing away his great talents, he acquired a medical degree and fulfilled his ambition of establishing a hospital on the edge of an African jungle for the care of natives. The relation of the seemingly insurmountable obstacles he encountered, his method of maintaining his organ playing technique, his eventual triumph through eliciting the interest and support of citizens of many countries proves fascinating reading. That anyone could have the stamina to accomplish so much in a lifetime makes the ordinary industrious individual seem a sluggard. Truly Dr. Schweitzer's life is a demonstration of the truth that "he that loseth his life for my sake shall find it."

—C. B. D.

SURGICAL AND MAXILLOFACIAL PROSTHESIS. Oscar Edward Beder, D.D.S. 51 p. Illus. Photo offset printing. Paper bound, New York: King's Crown Press, Columbia University, 1949. Price, $3.00.

In a brief, concise manner the author, who is dental surgeon in charge of the Surgical and Maxillofacial Prosthesis Clinic at Columbia University-Presbyterian Medical Center, defines and sets forth techniques, step by step, in splints, stents, protective shields in radiation therapy, obturators, corrective appliances for missing portions of the mandible, extraoral impressions, somatoprosthesis and cranial prosthesis. It is a practical and well-organized aid-book if one already has some basic knowledge of prosthetic materials.

Jerome A. Hilger, M.D.

HARVEY CUSHING: SURGEON, AUTHOR, ARTIST. Elizabeth H. Thomson. Foreword by John F. Fulton. 347 p. Illus. New York: Henry Schuman, 1950. Price, $4.00.

Harvey Cushing's friendship with Minnesota's John Fulton, professor of physiology at Yale's Sheffield Scientific School, is elaborated upon in this biography. Fulton wrote a long, detailed life of Cushing in which his own friendship with Cushing is depreciated. Hence, this friendship is examined in this book, which is shorter to save the reader time and spare him detail.

Cushing was a man of tremendous energy and gigantic accomplishments. He was such a giant among his fellow-surgeons that his behavior in the operating room was widely imitated. Cushing was a great surgeon, great author and a splendid artist. He was a friend to all the

great surgeons of the last half century—Kocher, Crile, the Mayo Brothers, Lord Moynihan, Fritz, Halsted, Lewis and Dean.

This book reveals Cushing as an intensely hard working, ambitious, courageous, hot-tempered surgeon who was tremendously interested in, and had tremendous identification with, his patients. He was moody, easily depressed and always overworked. His capacities were amazing. He was a bibliophile, collector of incunabula, an artist, a Pultizer Prize winner for his Sir William Osler biography; his monographs on brain tumors are the foundation stones for modern neurosurgery. He did make many trips to Europe, visiting historic medical sites, clinics and attending meetings. He rarely left the Eastern area of the United States, however, to visit the West.

Coleman J. Connolly, M.D.

THE COMMON HEMORRHAGIC DISEASES OF CHILDHOOD

(Continued from Page 1101)

control the hemorrhage. Pseudo-hemophilia (Von Willebrand's disease) may occur in children but it is a rare clinical entity.

Summary

The hemorrhagic diseases occurring in children may be congenital or acquired. The most common congenital disease is hemophilia. The diagnosis of this entity has been facilitated by the prothrombin consumption test. The importance of local treatment in controlling hemophilic bleeding is stressed. Congenital hypoprothrombinemia simulates hemophilia. Of the acquired hemorrhagic diseases, the hypoprothrombinemia of the newborn deserves recognition since it can be prevented by giving vitamin K to the mother. Thrombocytopenic purpura is a commonly acquired hemorrhagic disease. Usually recovery is spontaneous, but a small number of cases require splenectomy.

BIRTH AND STILLBIRTH CERTIFICATES

(Continued from Page 1132)

twenty weeks of gestation has been completed. Instead of the previously required birth and death certificate only a single stillbirth form is now necessary.

The Committee of Fetus and Newborn of the American Academy of Pediatrics defines a *premature infant* as one whose weight is 5 pounds, 8 ounces, (2500 grams) or less, regardless of estimated period of gestation and other criteria. In weeks of gestation, prematurity is the period from the beginning of the twenty-eighth week to the end of the thirty-seventh week. However, the period of gestation is notoriously unreliable and hence, birth weight is the more generally accepted definition.

A study of birth certificates shows a considerable discrepancy between the birth weight and full term or prematurity. Some 300 certificates listed infants weighing less than 5½ pounds as full term, while a similar number listed infants with weights of from 6 to 9 pounds as premature infants.

During the last twenty years a great and increasing interest has been taken in the incidence of tuberculosis in nurses and the methods to be used in an endeavour to reduce this. It is now clearly recognized that nurses, even in general hospitals where tuberculosis is rigidly excluded, run a far greater risk of developing this disease than do comparable members of the general population. Geoffrey Bewley, M.D. Dubl., *The Lancet,* March 25, 1950.

"Truth never grows old" *Thomas Fuller, 1639*

With the passing years, ideas, theories and conceptions may change with new discoveries and growing knowledge.

But truth never grows old.

No matter how widely the pendulum may swing, *truth* remains the center of its path.

Because of its inherent soundness, Dextri-Maltose® is the carbohydrate of choice in more hospitals than ever before. It enjoys the confidence of ever-growing thousands of physicians.

And the physician who prescribes Dextri-Maltose in infant feeding follows a course confirmed by a great mass of evidence, for no other carbohydrate enjoys so rich and enduring a background of authoritative clinical experience.

However the pendulum may swing, facts remain facts, and truth never grows old.

PHENEEN "ULMER"

The *Fast-acting* germicide-fungicide Preferred by doctors for cold-disinfection of surgical instruments

PHENEEN
Germicidal and Fungicidal
ULMER PHARMACAL COMPANY

- non-toxic
- non-staining
- non-corrosive
- non-irritating

The germicidal ability of this specialized brand of high molecular alkyl-dimethyl-benzyl ammonium chloride 1% is well established. Tests on Staphylococcus aureus and Salmonella typhosa exposed one minute show no growth on resubculture. PHENEEN "Ulmer" contains rust inhibitants which prevent rust and corrosion. It has a pleasant odor, contains no phenol, formaldehyde, iodine, mercury or other metals and does not leave residues on glass containers. May be diluted 1 to 40 for removing odors in lavatories, kitchens, laboratories and operating rooms. Available in quart, gallon, 4 gallon, and 12 gallon lots.

....PRONESTYL *Hydrochloride*

less toxic than quinidine

Indications and Dosage

IN CONSCIOUS PATIENTS

For the treatment of ventricular tachycardia:

Orally: 1 Gm. (4 capsules) followed by 0.5-1.0 Gm. (2 to 4 capsules) every four to six hours as indicated.

Intravenously: 200-1000 mg. (2 to 10 cc.). *Caution*—administer no more than 200 mg. (2 cc.) per minute.

Hypotension may occur during intravenous use in conscious patients. As a precautionary measure, administer at a rate no greater than 200 mg. (2 cc.) per minute to a total of no more than 1 Gm. Electrocardiographic tracings should be made during injection so that injection may be discontinued when tachycardia is interrupted. Blood pressure recordings should be made frequently during injection. *If marked hypotension occurs, rate of injection should be slowed or stopped.*

For the treatment of runs of ventricular extrasystoles:

Orally: 0.5 Gm. (2 capsules) every four to six hours as indicated.

IN ANESTHESIA

During anesthesia, to correct ventricular arrhythmias:

Intravenously: 100-500 mg. (1 to 5 cc.). *Caution*—administer no more than 200 mg. (2 cc.) per minute.

Supply

Pronestyl Hydrochloride Capsules, 0.25 Gm., bottles of 100 and 1000.
Pronestyl Hydrochloride Solution, 100 mg. per cc., 10 cc. vials.

* 8 cents' worth of Ovaltine (3 servings)

** 8 cents' worth of milk

As the bar chart so vividly indicates, Ovaltine is an exceptionally economical source of many essential nutrients. Using whole milk as the basis for comparison, the chart contrasts the relative amounts of nutrients supplied by 8 cents' worth of Ovaltine granules (3 servings) and by 8 cents' worth of whole milk. In 8 of the 13 nutrients listed, Ovaltine supplies greater amounts, and in the remaining 5, high proportions of the amounts found in milk.

It should be noted that Ovaltine specially enriches milk in those nutrients in which milk is low. Thus Ovaltine is not only economical in use but constitutes with milk an ideal protective supplementary food drink. It finds wide usefulness whenever dietary supplementation becomes necessary, either because of poor appetite, inability to consume a normal diet, or illness which often makes normal eating difficult or impossible.

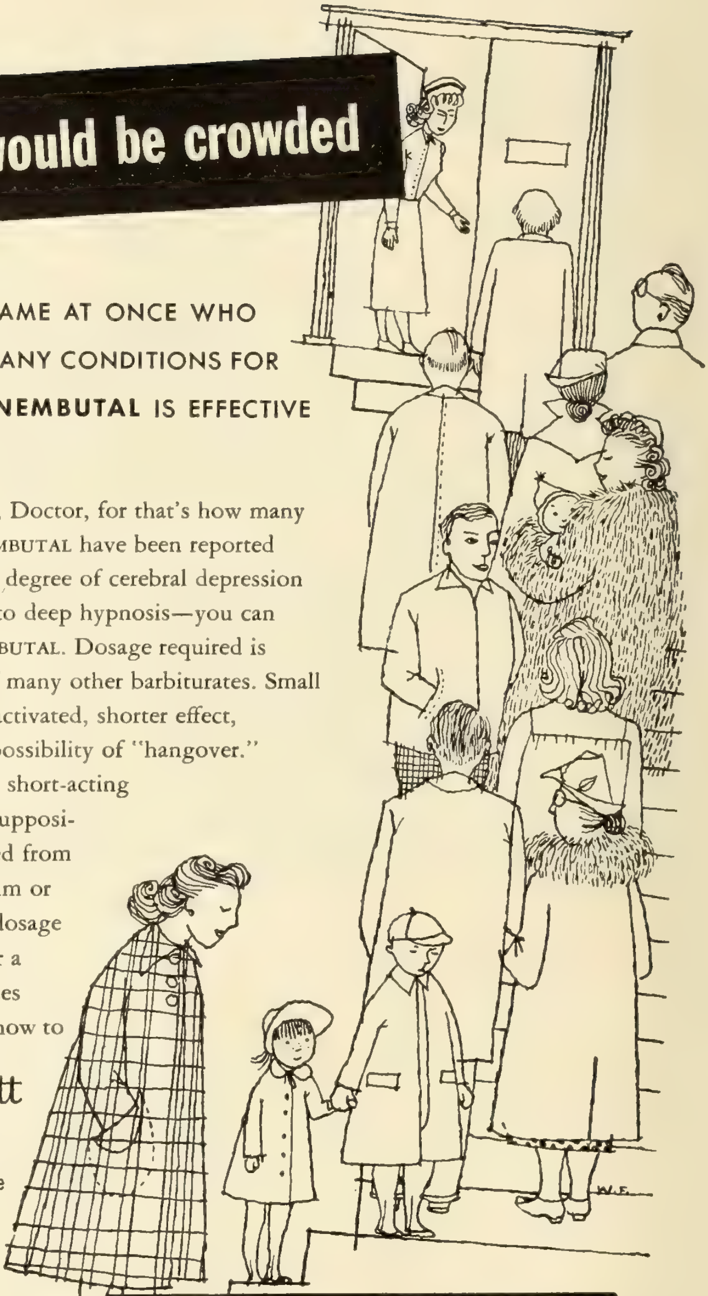
Your stairs would be crowded



IF ALL THE PATIENTS CAME AT ONCE WHO REPRESENT EACH OF THE MANY CONDITIONS FOR WHICH SHORT-ACTING **NEMBUTAL** IS EFFECTIVE

THERE'D be at least 44 on hand, Doctor, for that's how many clinical uses for short-acting NEMBUTAL have been reported in the literature. No matter what degree of cerebral depression you desire—from mild sedation to deep hypnosis—you can achieve it with short-acting NEMBUTAL. Dosage required is small, only about *one-half* that of many other barbiturates. Small dosage means less drug to be inactivated, shorter effect, wider margin of safety and less possibility of "hangover."

Pharmacies everywhere have short-acting NEMBUTAL as capsules, tablets, suppositories, elixir and solution prepared from the NEMBUTAL acid, or the sodium or calcium salts. Convenient small-dosage sizes simplify administration. For a 40-page booklet, "44 Clinical Uses for NEMBUTAL," just drop a line now to Abbott Laboratories, North Chicago, Ill. Abbott

In equal oral doses, no other barbiturate combines QUICKER, BRIEFER, MORE PROFOUND EFFECT.

NOTE THE NAME

Nembutal®

(PENTOBARBITAL, ABBOTT)

in active rheumatoid arthritis, the "best agent . . . that is readily available."[1]

Many therapeutic agents have been advocated for the treatment of active rheumatoid arthritis, with varying degrees of success. Among those now generally available, gold is "the only single form of therapy which will give significant improvement."[2]

SOLGANAL® for intramuscular injection is practical and readily available therapy. It acts decisively, inducing "almost complete remission of symptoms" in fifty per cent of patients and definite improvement in twenty per cent more.[3]

Detailed literature available on request.

Suspension SOLGANAL in Oil 10, 25 and 50 mg. in 1.5 cc. ampuls; boxes of 1 and 10 ampuls. Multiple dose vials of 10 cc. containing 10, 50 and 100 mg. per cc.; boxes of 1 vial.

Keleket proudly presents the

29 Features
for better technic
easier operation
greater safety
Years in advance of any table

ultimate in x-ray equipment

The new Keleket "C" Supertilt Table

with 45° TRUE TRENDELENBURG

You'll concur with the radiologists who helped design this great new table and tested it for five years preceding introduction. Keleket's "C-Supertilt" Table offers more facility, far greater convenience in every technic, fluoroscopy, radiography and fluorography procedures such as encephalography, ventriculography, myelography and genitourinary work are performed with greater ease and safety.

Among more than a score of time and effort saving advantages is this table's rapid travel . . . just 21 seconds from horizontal to vertical. Bucky travels to within 3" of foot end. Full angulation, more than ever before available, is 135° . . . from true Trendelenburg—through horizontal to vertical.

Confirm the enthusiastic approval of noted practitioners and technicians.

WHEN OBESITY IS A PROBLEM

Clinicians have long noted that the forward bulk of the heavy abdomen with its fat-laden wall moves the center of gravity forward. As the patient tries to balance the load, the lumbar and cervical curves of the spine are increased, the head is carried forward and the shoulders become rounded. Often there is associated visceroptosis. Camp Supports have a long history among clinicians for their efficacy in supporting the pendulous abdomen. The highly specialized designs and the unique Camp system of controlled adjustment help steady the pelvis and hold the viscera upward and backward. There is no constriction of the abdomen, and effective support is given to the spine. Physicians may rely on the Camp-trained fitter for precise execution of all instructions.

If you do not have a copy of the Camp "Reference Book for Physicians and Surgeons", it will be sent on request.

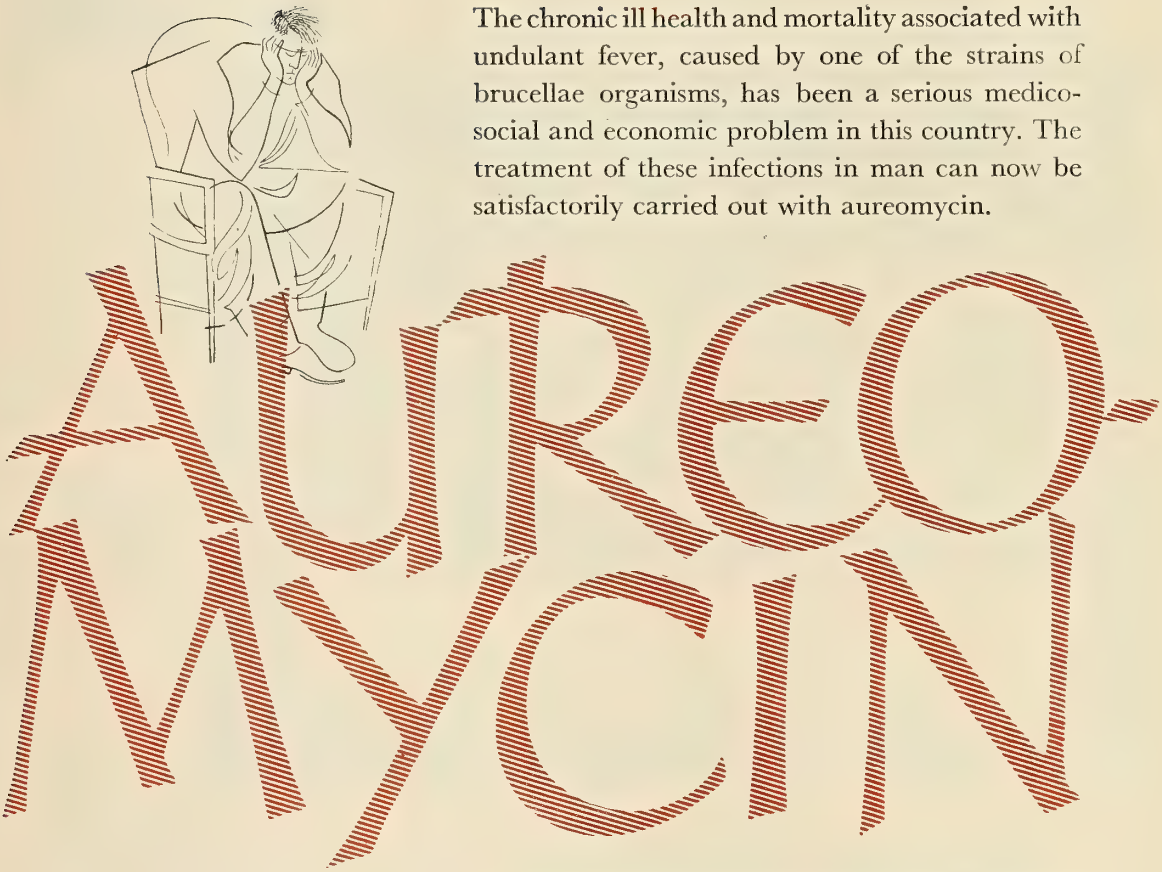
AUREOMYCIN
HYDROCHLORIDE CRYSTALLINE

in Brucellosis

The chronic ill health and mortality associated with undulant fever, caused by one of the strains of brucellae organisms, has been a serious medicosocial and economic problem in this country. The treatment of these infections in man can now be satisfactorily carried out with aureomycin.



Aureomycin has also been found effective for the control of the following infections: acute amebiasis, bacterial and virus-like infections of the eye, bacteroides septicemia, boutonneuse fever, gonorrhea, Gram-positive infections (including those caused by streptococci, staphylococci, and pneumococci), Gram-negative infections (including those caused by the coli-aerogenes group), granuloma inguinale, *H. influenzae* infections, *Klebsiella pneumoniae* infections, lymphogranuloma venereum, primary atypical pneumonia, psittacosis, puerperal infections, Q fever, rickettsialpox, Rocky Mountain spotted fever, surgical infections, subacute bacterial endocarditis resistant to penicillin, tick-bite fever (African), trachoma, tularemia and typhus.

Capsules:
Bottles of 25 and 100, 50 mg. each capsule.
Bottles of 16 and 100, 250 mg. each capsule.

Ophthalmic:
Vials of 25 mg. with dropper; solution prepared by adding 5 cc. of distilled water.

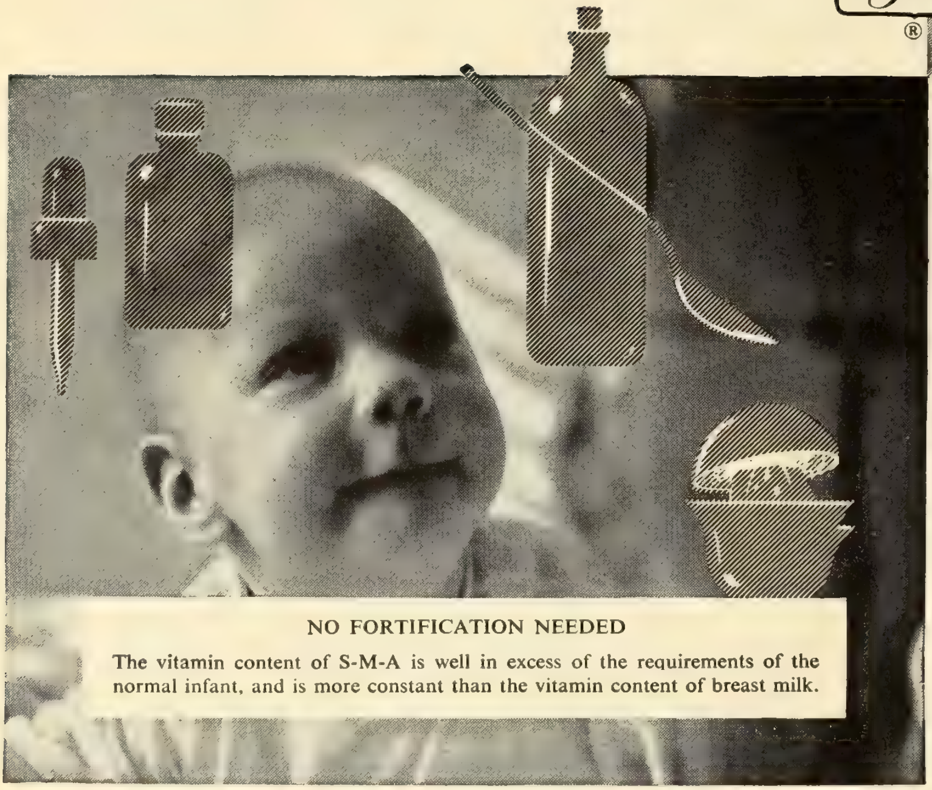
Wyeth®



NO FORTIFICATION NEEDED

The vitamin content of S-M-A is well in excess of the requirements of the normal infant, and is more constant than the vitamin content of breast milk.

A Complete, Protective Infant Food . . .

Ready-to-feed S-M-A is the most complete formula for infants. Its protective vitamins are administered in the most satisfactory way—right in the food and in each feeding. No danger of forgetting, no extra burden for busy mothers.

No infant food is more like breast milk than S-M-A—in content of protein, fat, carbohydrates and ash, in chemical constants of the fat and in physical properties.

S-M-A CONCENTRATED LIQUID—cans of 13 fl. oz.
S-M-A POWDER—1 lb. cans

S-M-A, diluted and ready to feed, provides in each quart the following proportions of the minimum daily requirements for infants.

VITAMIN A 5,000 U.S.P. units	333%
VITAMIN D 800 U.S.P. units	200%
THIAMINE 0.67 mg.	250%
RIBOFLAVIN 1 mg.	200%
VITAMIN C 50 mg.	500%
NIACINAMIDE 5 mg.	—

If You Are Called Into Service—
If You Are Too Old to Be Called Into Service—

In either event the rebellion in Korea affects your pocketbook in a major way, which will be reflected in your accounts receivable.

Soldiers Relief from their financial obligations has again been invoked making it impossible to enforce collection against anyone in the Armed Forces.

With our many years of valuable experience in handling the accounts for over 1,000 professional men, there is now an influx of professional accounts to this office due from patients about to enter Military Service where the possibility of immediate collection appears very problematical.

Our Recommendations

Based upon our experience in liquidation of accounts prior to, during, and after World War II

(1) Concentrate effort on the collection of accounts against patients who may be called in the Armed Forces.

(2) THE TIME TO COLLECT IS NOW because with inevitable continued inflation, increased salaries and wages, farm prices, commodity prices, there will be more money in circulation.

(3) That if you already have been called into the service or anticipate being called that you permit this qualified organization to act as your liquidating agent.

Our many years of experience handling accounts in the professional field plus our contractual relationship with fifty trade associations extending from coast to coast, proves we are rendering outstanding service.

Professional, commercial trade associations, and bank recommendations furnished.

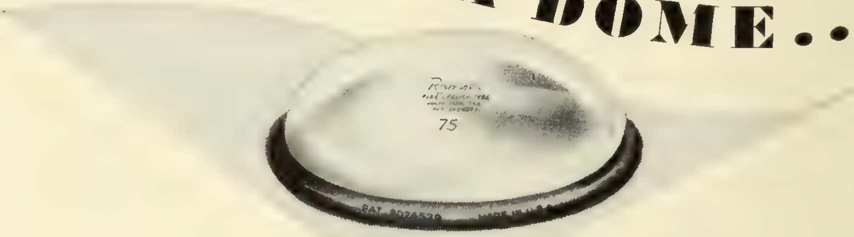
COMFORT IN A RIM..

Rim of a "RAMSES" Diaphragm exposed showing coil spring completely encased in cushion of soft gum rubber.

A coil spring with the necessary tension to hold it firmly against the vaginal walls can produce discomfort unless it is properly cushioned. Examine the rim of the "RAMSES"* Diaphragm and you will find that the coil spring is encased in soft rubber tubing, which acts as a protective cushion. This construction is patented and available only in the "RAMSES" Flexible Cushioned Diaphragm.

PROTECTION IN A DOME..



The "RAMSES" Flexible Cushioned Diaphragm is accepted by the Council on Physical Medicine and Rehabilitation of the American Medical Association.

A diaphragm dome must not only occlude the cervix—it must have a reasonably long life. The exclusive process used in manufacturing the dome of the "RAMSES" Diaphragm from pure gum rubber produces velvet smoothness, plus flexibility and long life.

A comparison will quickly reveal the advantages of supplying the patient with the patented "RAMSES" Flexible Cushioned Diaphragm.

"RAMSES" Diaphragms are available in sizes ranging from 50 to 95 millimeters in gradations of 5 millimeters.

HYPOPLASIA OF THORACIC AORTA CLINICALLY SIMULATING COARCTATION

ALLAN L. FERRIN, M.D., and JOHN F. BRIGGS, M.D.
Saint Paul, Minnesota
IVAN D. BARONOFSKY, M.D.
Minneapolis, Minnesota

WITH the current interest in cardiac and vascular surgery, it is felt advisable to report what is believed to be an unusual abnormality in the aorta. A thorough review of the American literature fails to reveal a previously reported case similar to this. Clinically our patient presented most of the findings of coarctation, and thoracotomy proved him to have narrowing of the thoracic aorta beginning at a point just distal to the ligamentum arteriosum.

Case Report

R. L., a twenty-five-year-old, single, white man, was first seen at Ancker Hospital on January 25, 1948, after sustaining a nasal fracture. He had known that he had a "heart murmur" since the age of eighteen and had been told that he probably had coarctation of the aorta after one physician had used intravenous-medications to relieve a blood pressure of "about 190."

On April 28, 1949, he was admitted to the hospital at the request of one of us (J. F. B.) for operation, again with diagnostic findings of coarctation of the aorta. At that time he was relatively asymptomatic except for extreme palpitation and some exertional dyspnea and fatigue. He gave no history of orthopnea, cough, or ankle edema and had no urinary complaints. As a child he had been able to exercise and swim without appreciable difficulty.

His past history revealed that he had developed tuberculosis of the thoracic spine and left hip at the age of three. The spine and hip were immobilized until he was seven years of age using a Bradford frame and casts. At eighteen years of age his left hip was ankylosed. Other operations included a tonsillectomy and an appendectomy. He had the usual childhood diseases (measles, mumps and chickenpox). Several years prior to admission he had pneumonia involving the left lung.

Physical examination revealed an asthenic, intelligent, young white man in no acute distress. His temperature was 98.7° F. and his pulse 60. A blood pressure recording in the right arm was 160/110 and in the left arm 162/94; in the right and left legs 110/90. There were scars over the left hip area from previous surgery and draining sinuses. There was a dorsal kyphoscoliosis with increased anteroposterior diameter of the chest (Fig. 1). Examination of the heart revealed cardiac enlargement with the apex at the sixth left intercostal space at the anterior axillary line. The rhythm was regular. There was a long harsh systolic murmur heard best in the left second interspace, and one observer (J. F. B.) heard a diastolic murmur over the base of the heart. Femoral pulsations were diminished in quality, but present. Popliteal, posterior tibial, and dorsalis pedis pulsations were not felt. Pulsations in the upper extremities were normal. The left hip joint was ankylosed and both legs were small in calibre and less muscular than normal.

Laboratory studies showed normal urinalyses with specific gravities between 1.010 and 1.025. The hemoglobin was 14.1 grams and red blood cell count 5.65 million. The white count was 7400 with 56 per cent polymorphonuclear cells, 39 per cent lymphocytes, 4 per cent monocytes and one per cent eosinophil. The erythrocyte sedimentation rate was 5 mm. in one hour. The blood urea nitrogen was 11.2 mg. per cent.

Chest fluoroscopy showed left ventricular cardiac enlargement and rib notching (Fig. 2). The aorta was not well visualized because of the marked spinal deformity consisting of acute angulation in the upper third of the dorsal spine. Films taken in this area showed destruction of several vertebral bodies, probably dorsal four, five, six, and seven. There was a minimal amount of calcification present and it was felt that the destructive process was probably due to tuberculosis.

The electrocardiogram showed sinus bradycardia and left axis deviation interpreted as probably being within normal limits. Renal flow studies preoperatively by Dr. John LaBree were also within normal limits.

Dr. Ferrin is chief surgical resident, Ancker Hospital, Saint Paul, Minnesota. Dr. Briggs is clinical associate professor of medicine at the University of Minnesota. Dr. Baronofsky is assistant professor of surgery at the University of Minnesota.

Presented before the Minnesota Society of Internal Medicine on May 27, 1950, at Duluth, Minnesota.

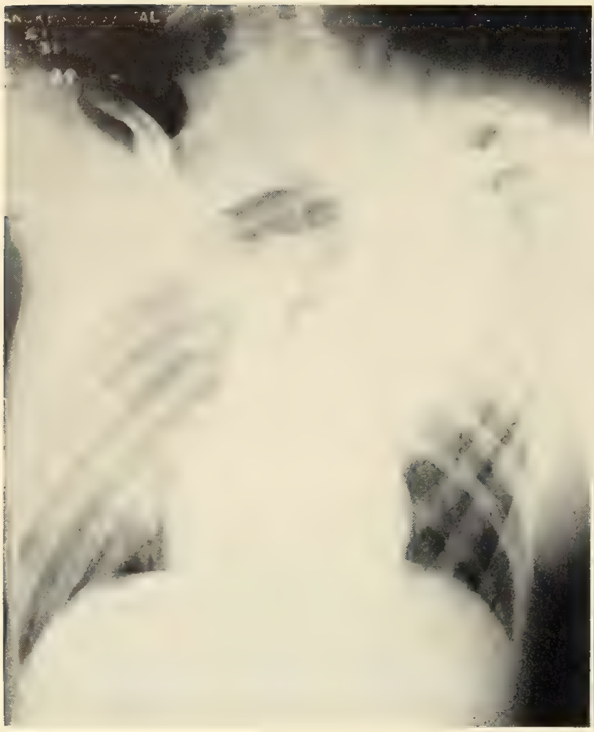

Fig. 1. Oblique x-ray chest showing the dorsal kyphoscoliosis.

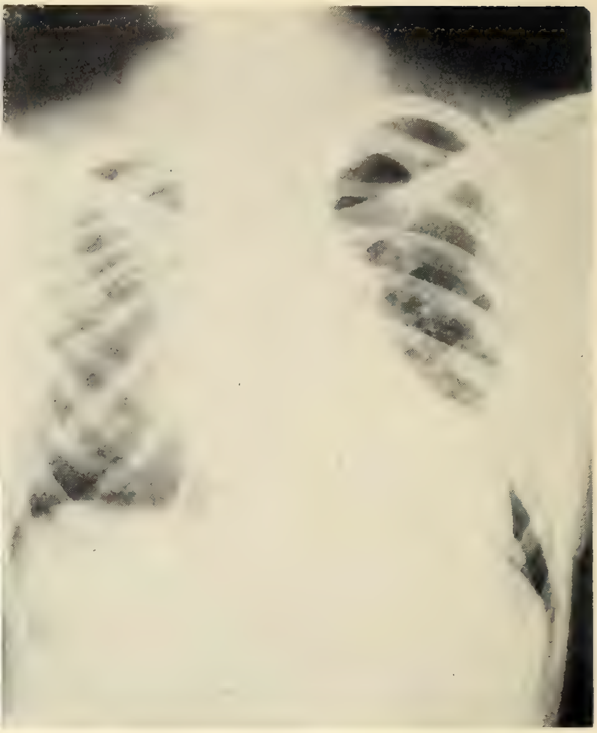

Fig. 2. Anteroposterior view of the chest showing left ventricular cardiac and rib notching.

On May 9, 1949, he was taken to the operating room but operation was postponed after the anesthesiologists were unable to introduce an endotracheal tube. Nine days later, on May 18, intubation was successful and an exploratory thoracotomy was performed under pentothal-curare-nitrous oxide anesthesia. The pleural cavity was entered through the left posterolateral aspect of the chest with excision of the sixth rib. The vessels around the scapula were markedly dilated. The left subclavian artery was found to be dilated to a diameter of 3 cm. The arch of the aorta also measured 3 cm. in diameter (circumference 9.42 cm.). After incising the mediastinal pleural covering the aorta, a narrowing was found in the aorta just distal to the ligamentum arteriosum and also to the point of most marked dorsal kyphosis. The aorta at this point measured only 1.5 cm. in diameter, and exposure of the thoracic aorta by dissection down to the diaphragm failed to reveal any change in its size. A good flow of blood was felt going through this portion of the aorta.

Because of the nature of the abnormality, further operation was deemed inadvisable. After introducing two rubber catheter drains into the pleural space, the chest wall was closed in layers with interrupted silk sutures. His postoperative recovery was uneventful.

Discussion

Hypoplasia of the aorta was described first in 1761 by Morgagni, and by 1907, according to Ikeda,[8] over 100 cases had been reported in the literature. Recently the reports have been more sporadic and all have concerned themselves with narrowness of the entire aortic system or well-localized areas (coarctation). Burke,[5] Apelt,[2] Ikeda,[8] and Werley, Waite, and Kelsey[13] give excellent descriptions of hypoplasia involving the entire aortic system.

Coarctation was first recognized, according to Abbott,[7] in dissecting room specimen by Paris in 1791. In the past two decades the literature has contained numerous reports and reviews which need not be discussed here. The surgical treatment of this condition was introduced independently by Gross and Crafoord in 1945. Bahnson, Cooley and Sloan[3] reported two cases of coarctation below the ductus arteriosus and added ten from the literature. Parker and Dry[11] reported a case of aortic stenosis between the left common carotid and left subclavian arteries. Maycock[10] and Kondo et al[9] presented cases with complete occlusion in the mid-abdominal aorta.

From the available literature, then, our case seems unusual in that it combines the clinical picture and pathological findings of both coarctation and hypoplasia. Unfortunately we do not know the calibre of the abdominal aorta, but must assume that it, too, is hypoplastic.

The incidence of hypoplasia of the aorta varies in several reports. Ikeda[8] states that out of 14,305 autopsies at the University of Minnesota there were eight cases; he also states that Von Ritook reported fifty-seven cases in 395 autopsies and Cabot reported nineteen cases in 1846 autopsies. Werley et al[13] found twenty-five cases in 4500 autopsies. Paul White[14] states that simple hypoplasia of the aorta is probably the commonest of the congenital aortic anomalies, but in high degree is relatively rare and then usually associated with other cardiovascular defects. Maude Abbott[7] found twenty-one cases of hypoplasia among the 200 cases of coarctation which she reviewed. She commented that since the ascending aorta is so commonly secondarily dilated as a result of coarctation, the original narrowing at this point (ascending and aortic arch) may be obscured in patients attaining adult life. Thus she concludes that the association of congenital hypoplasia of the arterial tract with coarctation may be more frequent than is apparent from reports.

In normal males between the ages of twenty and thirty years, the average circumference of the thoracic aorta studied at necropsy was 4.4 cm., according to Ikeda.[8] According to these figures our case, with a circumference of 4.7 (diameter 1.5 cm.) falls within normal limits. However, our measurement seems to be near the lower limits of normal and was taken on an aorta distended with blood so that the size is not well comparable with the size of the aorta found at necropsy. Furthermore, Werley, Waite and Kelsey[13] state that the normal internal circumference of the aorta at its widest point equals 5.5 cm., and they present one case of hypoplasia in which the thoracic aorta measured 1.37 cm. in internal diameter and two others in which the measurements were 1.11 in diameter. Inasmuch, then, as our measurements were taken of the outside diameter and on a living patient, we feel that for practical purposes this aorta must be considered hypoplastic.

In considering an explanation for the hypertension in the upper extremities in our case, several factors seem important. According to the laws of the dynamics of circulation[4,13] we find we have increased resistance due to the long narrowing of the aorta. Since the volume of flow is proportional to the fourth power of the diameter (Poiseuille law), there is reduced flow to the lower extremities. In compensating for this, the collateral circulation proximal to the narrowing developed. The gradual dilatation of the aorta, acting much like an aneurysm, produced a vicious cycle following the principle that in a tube of varying diameter the velocity varies inversely and the lateral pressure directly with the sectional area of the tube. Abramson[1] feels that the increased systolic blood pressure in the upper extremities is largely the result of arteriolar vasoconstriction, although the resistance to blood flow through the narrowest portion of the aorta probably plays a role. The renal blood flow studies which were within normal limits tend to eliminate the kidneys as a factor in the hypertension.

This case allows interesting speculations as to pathogenesis in view of the associated healed (?) tuberculosis of the thoracic spine and marked kyphoscoliosis. Certainly one must admit that failure of the aorta to have developed normally might well be secondary to the marked spinal deformity, particularly since the area of narrowness began immediately adjacent to the point of greatest projection of the spine into the thorax. Burke,[5] in 1902, interestingly enough, discussed the etiological relationship of aortic hypoplasia and tuberculosis. He concluded that arterial insufficiency tended to predispose to the infectious process. Here we feel that mechanical effects may have been more important. Certainly, however, we cannot deny that the coexistence of these two entities may have been purely coincidental.

Angiographic studies of this case would certainly have been of value, but unfortunately at the time he was submitted for operation, the technique of angiography at our hospital had not been perfected to the point where the risk of the procedure seemed justified.

The question of whether or not this lesion is congenital or acquired arises. In favor of this being congenital are the associated cardiac murmurs and possibly the extent of the hypoplasia. On the other hand, the fact that the narrowing began adjacent to the point of most marked dorsal kyphoscoliosis is in favor of its being acquired. We do not feel that there is sufficient evidence to answer this question completely.

Summary

1. A case of an unusual abnormality in the thoracic aorta which clinically simulated true coarctation of the aorta has been presented.

2. A brief review of the literature on coarctation and hypoplasia of the aorta is included.

(Continued on Page 1203)

TREATMENT OF AURICULAR FIBRILLATION FROM THE STANDPOINT OF THE GENERAL PRACTITIONER

ROBERT H. CONLEY, M.D.
Mankato, Minnesota

THE highest degree of auricular disturbance is called auricular fibrillation. In this condition, the number of auricular impulses is very great, 400 to 600 per minute. Total irregularity (delerium cordis) has been thoroughly evaluated by Thomas Lewis[7] and other early cardiologists. The classical theory of circus movement to explain this abnormality has been universally accepted and has only recently been challenged by Pranzmetal of Los Angeles who photographed exposed hearts of dogs using high speed colored film reproducing the heart action in slow motion.

Auricular fibrillation is the most common cardiac irregularity requiring treatment encountered in hospital records. It probably ranks third in frequency as a disturbance of rhythm, premature beats and paroxysmal auricular tachycardia ranking first and second. White and Jones[13] analyzed 3,000 patients with cardiac symptoms and signs in 1928. They found 376 of this group (12.5 per cent) with auricular fibrillation; 309 (82.2 per cent) were permanent and 67 (17.8 per cent) paroxysmal in type.

Auricular fibrillation is rare in infants and children and is most commonly found in individuals over forty years of age. It is usually associated with organic heart disease, but may occur in the absence of heart disease associated with excessive use of alcohol, tobacco, or with excitement, trauma, operations (particularly thoracic), acute infections (pneumonia) or chronic infections such as cholelithiasis. White states that the condition is fundamentally a functional disorder and is not in itself to be classified as heart disease. However, in hospitalized cases auricular fibrillation is associated with organic heart disease in a high percentage of cases. Auricular fibrillation occurs frequently in rheumatic valvular heart disease. The triad of rheumatic heart disease, mitral stenosis and auricular fibrillation is a common occurrence. Auricular fibrillation is less frequent in rheumatic heart disease with aortic valvular deformities. In rheumatic heart disease the fibrillation is generally paroxysmal and disappears spontaneously only to recur when valvular deformities are present. It is unusual in congenital, subacute bacterial and syphilitic forms of cardiac involvement and in chronic cor pulmonale, although it does occasionally appear in these conditions. In an analysis of 575 cases of auricular fibrillation by McEacheon and Baker[8] the chief etiologic relationships were: rheumatic heart disease 34.4 per cent, arteriosclerotic heart disease 31.1 per cent, hypertension 16.9 per cent, thyrotoxicosis 7.5 per cent, emphysema 5 per cent, syphilis 3 per cent, and miscellaneous 2.1 per cent.

On observation of the fibrillating heart the auricles appear dilated and inco-ordinated. Contraction is replaced by quivering of the auricular surfaces, while the ventricles beat at totally irregular intervals. There is a decrease in cardiac output per minute and diliatation of the heart irrespective of whether or not heart disease is present, and the state of compensation. Kerkhoff[5] utilizing the acetylene method of determining cardiac output found the efficiency of the heart in mitral stenosis with auricular fibrillation increased 25 per cent when regular rhythm was restored by quinidine even though prior to conversion the rate was kept at 60 to 70 beats per minute with digitalis. No one, as yet, has reported a series of cases studied by means of right heart catheterization before and after conversion.

During tachycardia there is so little blood in the ventricles when systole occurs, that some contractions fail to open the aortic valve and to expel enough blood to form a radial pulse, accounting for the pulse deficit. At the next systole there will be a greater accumulation of blood, so that the radial pulse will be barely palpable or larger, which accounts for variations in pulse volume. The pulse deficit represents expenditure of cardiac energy which is wasted.

Symptoms vary with auricular rate, the underlying functional state of the heart, and the duration of the auricular fibrillation. In the paroxysmal form, when the ventricular rate is rapid, the picture is similar to that seen in paroxysmal tachycardia except for the arrhythmia and other diagnostic signs of auricular fibrillation. In the chronic form, no symptoms may be present or, if present, they range from palpitation, fluttering,

---

Read at the annual meeting of the Southern Minnesota Medical Association, Mankato, Minnesota, September 11, 1950.

skipping, pounding and anxiety, to pallor, cyanosis, breathlessness, syncope, faintness and collapse. Congestive heart failure may be coincidental with, contributed to, or entirely caused by the rapid irregular ventricular rhythm. While angina pectoris is uncommon in chronic auricular fibrillation, it may occur in the paroxysmal form with a rapid ventricular rate when the patient has a predisposing underlying chronic coronary insufficiency. The patient may show distress or fear, may complain of the tumultous action, may be irritable or may have vague pain. The symptoms are exaggerated when the patient is hypersensitive.

The clinical diagnosis is not difficult; and it is easier if the ventricular rate is quite rapid or before digitalization. On ausculation the rhythm is usually totally irregular. Attempts at discerning any regular sequence of heart beats is met with failure. The pulse is usually slower, and is irregular and of variable volume. Simultaneous auscultation of the heart and palpation of the radial pulse reveals the magnitude of the pulse deficit. The ventricular rate and pulse deficit increase with moderate exercise while the irregularity due to premature contractions is likely to disappear. The ventricular rate may be 180, but usually is 130 to 160, and occasionally is as low as 70 or 80 even without digitalis. Carotid sinus pressure retards the ventricles transiently by depressing the A-V conductivity, bringing out the irregularity at slow rates. The enhancement of A-V conductivity and the acceleration of the ventricular rate by exercise, atropine and amyl nitrate may disclose the irregularity of the beating heart. The cardinal signs of auricular fibrillation in the electrocardiogram are: (1) the absence of P waves, (2) the presence of irregular ventricular beating, except in complete A-V block, and (3) the presence of undulations (F waves) of varying amplitude, contour and spacing, whose rate usually falls between 350-600 per minute.

Sudden death from auricular fibrillation is rare except in the forms associated with coronary disease or an embolus. The formation of thrombi in the auricles, especially in the auricular appendages, is common and may result in emboli to the vascular beds especially evident in the lung, brain, extremities, mesentery, and heart. Sudden death may be caused by emboli or by a ball thrombosis in the mitral wave. When the ventricular rate is slow, patients maintain an adequate circulation for years without progressive cardiac enlargement or failure. Others carry on satisfactorily when the rate is controlled. The paroxysmal form may lead to no apparent harm in the course of years. Chronic fibrillation does not in itself afford a serious prognosis, but as a complication of heart disease, it comes on usually toward the end of the natural history of the disease.

The treatment of auricular fibrillation is not a standard procedure. Each individual needs to be evaluated clinically and a thorough understanding of the basic cardiac disease should be sought out before therapeutic measures are instituted. Since emotion and exertion tend to speed up the rate of the ventricles, they should be minimized as far as practicable.

If the ventricular rate is slow, if it accelerates only moderately on exercise, and if the patient is without symptoms, special treatment is not indicated, although the use of quinidine should be considered. If the rate is rapid, especially if the patient has heart disease, rest in bed is indicated if possible until it is retarded, and is required if there is failure.

Digitalis is by far the best drug to administer in auricular fibrillation; in fact, its reputation as a cardiac drug rests primarily on the brilliant results obtained when the condition is attended by a rapid ventricular rate and congestive heart failure. The faster the ventricular rate, the more urgent the necessity for therapy to retard the beating of the ventricles. Digitalis acts primarily to reduce the number of impulses passing to the ventricles by depressing A-V conduction, but aside from that it also relieves congestive failure. Digitalis is given either to build up the concentration of the drug in the heart (digitalization) or to maintain the concentration once established. The rate of digitalization varies with the urgency of the case. Digitalis should be given until the desired effect is obtained or mild toxic symptoms appear. The chief toxic manifestations of digitalis are anorexia, nausea, vomiting, diarrhea, yellow or colored vision, frequent premature beats, sino-auricular block and sinus standstill.

In determining the amount of digitalis to be used the goal of 60 to 80 beats per minute at the apex should be kept in mind. If the patient is in bed and digitalis has not been given in three weeks, digitalization may be undertaken rapidly by giving in twenty-four hours by mouth a total of 1.8 gm. of the powdered leaf (U.S.P. XII). In the average case, digitalis folea (U.S.P. XII) 0.2 gm., or digitoxin 0.2 mg. orally three times daily for three days is recommended. This is a rough guide and the patient should be placed on a maintenance dose earlier if the desired therapeutic effect is obtained sooner and conversely should be delayed until more digitalis has been given if the patient responds poorly to the above dosage. The amount of digitalis required is influenced by the body weight, the status of the myocardium, the rate of absorption, the speed of mobilization and excretion, and the amount of edema fluid. These factors operate to affect the levels of digitalis concentration in the myocardial tissue and the level required for therapeutic response. The lowering of the ventricular rate to 70 to 80 beats per minute and the lowering in pulse deficit are valuable indices of the therapeutic response to digitalis. Similarly the disappearance of edema, increased urinary output, weight loss and disappearance of other signs and symptoms of congestive failure should be used. Individuals who reach the full therapeutic or toxic level before four or five days usually require smaller maintenance doses (0.1 gm. of leaf, 0.1 mg. digitoxin), and those who take longer than a week usually require more digitalis as a maintenance dose. The appearance of toxic signs and symptoms calls for discontinuation of the drug. However, it should be resumed and administered cautiously following disappearance or evidence of toxicity.

In the treatment of ventricular paroxysmal tachycardia caused by digitalis excess, quinidine, papaverine, potassium or magnesium have been used to sooth the ectopic pacemaker.

In more urgent cases digitalization may be carried out more rapidly, the full digitalization dose being given in one, two or three doses. It may be given in the form of digitoxin *(Digitaline nativelle)* 1.2 mg. The entire dose or portions thereof may be given orally, intravenously or intramuscularly. Orally the medication is absorbed totally and gives a full effect in a matter of three to four hours, the effect lasts for several days and this drug does not irritate the intestinal tract in therapeutic doses. Its effect parenterally (intravenously or intramuscularly) is similar to oral administration, and the parenteral route is to be used when the oral route is not available. In giving such large doses of this or any other digitalis preparation, extreme caution should be exercised if the patient has received digitalis recently, especially if edema is present, because ventricular fibrillation can readily be caused. Edema fluid contains digitalis in digitalized patients, and when absorbed the digitalis re-enters the blood stream for distribution together with that administered. It takes two weeks or more for digitalis to be excreted.

If more rapid effects are essential, quicker acting digitalis preparations are to be used intravenously with the same care as with large doses of digitoxin to avoid overdigitalization. The purified crystalline glucoside, lanatoside C, may be used. It is faster in speed of action and rate of excretion when given intravenously than digitoxin. Its effect intravenously begins within an hour. The digitalizing dose of lanatoside C intravenously is 2 mg. It should be mentioned that strophanthin intravenously has been used for rapid digitalization; however, it is rarely being used at the present time.

Occasionally it is desirable to treat auricular fibrillation on an ambulatory basis. Dosage schedules should be calculated on total digitalization plus the total maintenance dose over a given number of days. It is advisable to carry out the digitalization over a period of several days with smaller amounts being given at the end of the schedule. Ambulatory therapy intimates loss of direct supervision, therefore, the patients should be closely instructed in regard to the toxic effect of the medication.

Paroxysmal auricular fibrillation is not an uncommon finding in a general practitioner's office. If paroxysms are infrequent or brief in an otherwise well subject, specific treatment is not required, beyond avoidance of precipitating factors. If, however, the attack has persisted for several hours, if tachycardia prevails, or if the patient is uncomfortable, reassurance, bed rest and sedation should be prescribed. Lack of response to the above treatment indicates the necessity for digitalization which should then be carried out. If the normal rhythm has not been restored by digitalization, quinidine is indicated. Recurrent fibrillation is occasionally prevented by digitalization followed by maintenance doses.

When auricular fibrillation occurs in hyperthyroidism, the ventricular rate is reduced with digitalis. Larger than the average amounts may be required for adequate slowing. Maintenance doses are continued during treatment with propylthiouracil, iodine, et cetera. After operation in most instances, a few days to many weeks, the rhythm reverts to normal spontaneously. When this occurs, digitalis is discontinued if heart failure does not require its continued use. If normal rhythm has not recurred after an adequate postoperative period the use of quinidine is considered.

Recent myocardial infarction followed by auricular fibrillation with a rapid ventricular rate is a situation calling for heroic therapy. Rapid digitalization is carried out followed by quinidine therapy. Quinidine is advisedly first preceded by digitalis in order to avoid further ventricular acceleration which quinidine may bring on as it slows auricular activity.

Quinidine is a far more effective drug in reestablishing sinus rhythm than digitalis. Wenckebach first introduced quinidine in 1914 for the treatment of paroxysmal auricular fibrillation. Most authorities agree that patients with auricular fibrillation should be digitalized and well compensated before conversion with quinidine should be attempted; however, in recent articles McMillan and Welfare[9] and Askey[1] state that in patients with congestive failure persisting after complete digitalization, rest, diuretics, and low sodium diet, administration of quinidine to abolish auricular fibrillation at times produces remarkable results.

According to recent articles the only absolute contraindication to quinidine is idiosyncrasy to the drug itself.[1,4,9] Relative contraindications are pronounced cardiac enlargement, congestive failure, heart block, subacute bacterial endocarditis and angina relieved by fibrillation.

Symptoms of toxicity include the symptoms of cinchonism such as tinnitis, vertigo, visual disturbance, headache, confusion, syncope, fever, nausea, vomiting, diarrhea, cutaneous rash and angioneurotic edema. Serious hazards include ventricular fibrillation, cardiac asystole or respiratory arrest.

At the present time most cardiologists agree that the incidence of embolic accidents with conversion has been greatly overemphasized. Vika, Marvin and White[12] stated that it seemed justifiable to conclude that embolism occurs less frequently under quinidine therapy than under ordinary treatment. In 200 cases of auricular fibrillation without quinidine therapy, these investigators observed nine instances of embolic phenomena (4.5 per cent) whereas in 484 cases of auricular fibrillation treated with quinidine emboli accured in fifteen cases (3.1 per cent).

Before attempting the restoration of normal rhythm with quinidine the patient should be placed on bed rest and adequately digitalized. Fahr[2] recommends a test dose of 3 grains be given. The following morning 3 grains are given at 8, 9, and 10 a.m. Each succeeding day 3 grains are added to the previous dose (Ex.: 6 grains, 3 grains, 3 grains, et cetera). If necessary the total dosage may be raised to 36 grains. He reports a total conversion to normal rhythm in 65 per cent of cases (over 500 cases of fibrillation and flutter).

Levine[6] recommends 0.2 gm. of quinidine to start and this is increased by 0.1 gm. with each dose. Medication is given three times a day. Up to 1.5 gm. in a single dose have been given but this is not advisable under ordinary circumstances.

Following digitalization, Katz[3] uses a schedule of 0.4 grams every two hours until the arrhythmia is broken or until five doses have been given. This may be repeated for two or three days, the dose being increased each day by 0.2 gm.

If normal rhythm is restored, a maintenance dose of 0.2 gm., one to three times daily, may be used. If normal rhythm is restored once, but fibrillation recurs while quinidine is being given, further attempts are not recommended. After normal rhythm is restored prophylactic maintenance dosage should be given for a period of weeks and then stopped, in order to determine whether the ectopic pacemaker is inactive.

"ANTABUSE" (TETRAETHYLTHIURAM DISULFIDE) IN THE TREATMENT OF ALCOHOLISM

J. C. MICHAEL, M.D.
Minneapolis, Minnesota

TO the list of modifications of the treatment of alcoholism proposed in recent years, Jacobsen and Martinsen-Larsen of Denmark contributed clinical reports two years ago on the combined effect of alcohol and Antabuse® (tetraethylthiuram disulfide). Pharmacological and toxicological investigations and animal experiments were outlined by Hald, Jacobsen, Larsen, Asmussen, Jorgensen and others.

The purpose of this presentation is to outline preliminary considerations and to record clinical experiences with the treatment of twenty-six patients during the past year.

Preliminary Considerations

Cyanamides were shown by Koelsch in 1914 to produce toxic effects in workers handling those chemicals when they imbibed alcohol even in small amounts. The symptoms included redness of the face, feeling of giddiness, headache, heightened pulse and respiratory rates. Continuing for thirty to ninety minutes, these were terminated by fatigue and somnolence.

Another sensitizing agent, a fungus termed coprinius atramentarius, had been found to be toxic to humans only when alcohol was consumed. Accounts of non-fatal poisoning in a family are referred to by Hald, Jacobsen and Larsen.

Toxicity of tetraethylthiuram disulfide is relatively low; the drug is not soluble in water and is not excreted by the kidneys. A dose of 2 to 3 grams per kilogram of body weight has been proved fatal to dogs and rabbits. Prominent symptoms preceding death include progressive depression, ataxia, slowing of the pulse rate and respiration. Kidney degenerative processes were found to exceed those in the lungs and liver. On the other hand, the continued daily administration of 1 milligram to rats and 60 milligrams to rabbits for ten months failed to reveal impairment of growth, of body weight or of the elements of the blood. Single doses of 3 grams, or of continued dosages of 0.25 to 1 gram daily in man induced no deleterious results in most instances. Danish workers found that within twelve hours following the ingestion of 1 gram of antabuse, the intake of alcohol produced, after the elapse of five to fifteen minutes, first a feeling of heat in the face and soon thereafter observable reddening of the face, neck and chest. The pulse rate rose to 120 and higher, blood pressure declined slightly, the alveolar carbon dioxide was decreased, cardiac output was increased up to 50 per cent in the resting person, and up to 15 per cent if the subject was moderately active.

Nausea, if at all present, occurs within an hour after the intake of alcohol. Vomiting is less frequent. Dizziness and coma appear to be the result of relatively higher doses of alcohol. Blood pressure falls significantly in these instances. There is the noteworthy observation that inhalations of pure oxygen eliminate the effects upon respiration and cardiac output.

Antabuse administration combined with alcohol consumption brings on a five- to ten-fold rise of the blood acetaldehyde level above that determined when the antabuse is omitted; exact reactions concerned are unknown. A concentration of 5 to 10 milligrams per hundred cubic centimeters in the blood suffices to induce a rise in skin temperature. Coma appears when these figures rise to 100 milligrams or more. Tolerance, apparently relatively high in heavy drinkers, at first decreases gradually. In doses of an average drink, alcohol tends to remain in the blood for some sixty to ninety minutes following intake, and during this period of time antabuse continues capable of producing characteristic symptoms, which are followed by a short period of fatigue and somnolence. The saturation dose of antabuse in humans is not determined. Rabbit experiments are reported to have shown that acetaldehyde formation is augmented as the dosage of alcohol and the drug, the latter up to 0.3 gram per kilogram of body weight, are increased. Hypersensitivity to alcohol is observed to begin three to four hours after antabuse administration in a single dose and to continue for the following twenty-four hours.

Read at the annual meeting of the Southern Minnesota Medical Association, Mankato, Minnesota, September 11, 1950.

Presented at Southern Medical Association Meeting, Mankato, September 11, 1950.

"Antabuse" trade mark for brand of Antabus (tetraethylthiuram disulfide) as manufactured by Ayerst, McKenna and Harrison Limited, who furnished a supply of "Antabuse" employed in this investigation.

Clinical Experiences with Twenty-six Patients

Of our twenty-six patients, six were treated at the Minneapolis General Hospital and twenty in private hospitals. There were twenty-two males and four females. Ages ranged from the mid-twenties to the early fifties, about half in the fifth decade. Nineteen listed themselves as married, one as single, five divorced, one widowed. About one-half of this group of alcoholics gave a history of drinking for their past fifteen to twenty years. With few exceptions, all preferred whiskey and beer. Two preferred beer alone, and one reported that he confined himself to gin. Wine and rum were resorted to by several on some occasions. Other interesting factual material concerning personal history, education, vocational achievements, familial and other interpersonal relationships, hereditary accounts, range of individual abilities and other psychologic test records, behavior in conflict with the law, previous treatments, et cetera, cannot be detailed here. Essentially these data reveal no uncommon deviations.

Objective examinations by bodily systems, psychiatric interviews, special psychologic tests and the following technical examinations were made: (1) routine urine and blood, including the sedimentation rate, (2) fasting blood sugar and sugar tolerance curve, (3) CO_2 combining power, (4) urine concentration and dilution, (5) phenolsulfonphthalein, (6) electrocardiograms, (7) liver function, (8) x-ray of chest, (9) basal metabolism rate, (10) electroencephalogram, and additional procedures in some instances when indicated.

Significant visceral disease, if present, was regarded as a contraindication to antabuse therapy. Naturally, the patient to be treated was expected to feel an unwavering desire to stop drinking liquor and to plan satisfactory co-operation in the long therapeutic program for the future, of which the first two weeks or more in the hospital were to be regarded only as a relatively minor or introductory feature.

Antabuse administration is routinely as follows: On the first day one 0.5 gram tablet is given four times; three times on the second day, twice on the third day, and once in the morning of the fourth day. Three hours following the last dose, the patient takes an ounce to an ounce and a half of whiskey. The attending hospital personnel is expected to have at hand medicinal and mechanical aids to combat possible symptoms of shock. In addition to general observations, pulse, respiratory and blood pressure notations are made every five minutes for thirty to forty-five or more minutes after the ingestion of whiskey.

The following is an illustrative case report:

Case 1.—J. S., a male, aged forty-eight, married, a construction worker, gave a history of excessive periodic drinking for eighteen years. He had been under Alcoholics Anonymous guidance for some time. There was a history of a "bleeding gastric ulcer" on one occasion in January, 1949. Physical and laboratory data had been negative. He was started on antabuse regime, as outlined above, and on September 6, 1949, he was given 40 c.c. of whiskey, the fourth day. Blushing to a moderate degree appeared five minutes later, preceded by two minutes of a feeling of heat in the head and neck. Slight dyspnea started also in five minutes and perspiration was obviously increased at the same time. Headache of a moderate intensity was complained of within fifteen to forty-five minutes. His pulse rate rose from 80 to 100 after a ten-minute interval; to 125 after twenty-five minutes. Blood pressure fell from 128/86 to 110/80 after twenty-five minutes. There was a slight feeling of dizziness and precordial pain from ten to twenty-five minutes after taking the whiskey. Acetaldehyde odor was also detected during the same period. After moderate somnolence for a half-hour the patient was free of distress.

In two patients of the Minneapolis General Hospital series the state of shock was encountered. The next two reports concern these subjects.

Case 2.—J. C. G., a male, aged forty-seven, divorced, a railroad freight conductor, entered the hospital with history of drinking three bottles (fifths) of whiskey per day for the last six weeks. Food intake had been minimal during that time. Also, during this period he had been seeing "gremlins"; he seemed to realize that these visions were not real. Except for an appendectomy and herniorrhaphy his history had been negative. On admission, his sensorium was found to be clear, he was oriented and co-operative, but he was noted to be engaged in kicking the gremlins down the drain! On September 9 he was given 2 grams of antabuse at 8:00 a.m.; on the 10th, 1.5 grams; on the 11th, 1 gram; on the 12th, 0.5 gram at 8:00 a.m.; on the 14th, 0.5 gram at 10:30 a.m. At 2:25 p.m. on the 14th 1 ounce of whiskey was given. In ten minutes a slight increase in pulse rate and flush of face began to appear. This subsided without other phenomena. The next morning he was given 1.5 grams of antabuse and the following four days another 1.5 grams of antabuse, this at variance from the subsequently established routine. At 10:45 a.m. on the 19th, 40 c.c. of whiskey were given. At 11:10 a.m. his face appeared flushed; blood pressure, normally 118/80, fell to 70/50 in thirty minutes, and the pulse rate rose to 132 in fifteen minutes. The patient became unconscious. Thereupon coramine and caffeine sodium benzoate were injected intravenously and oxygen was administered under pressure. By 12:15 p.m. the patient began to respond, he appeared tremulous, his face was still flushed. He refused the food tray at 12:30 p.m. By 2:00 p.m. his condition appeared to be improved. At 2:30 the patient drank 200 c.c. of milk. By 3:00 p.m. he walked out in the dayroom but still seemed shaky. The next morning he awakened still complaining of some nausea and there was some emesis. At noon time he ate well and felt well until time of discharge.

The third case report indicates, furthermore, what may be expected when sugar metabolism is impaired. In the presence of such an abnormality, we would not again allow antabuse administration.

Case 3.—R. P., a male, aged thirty-one, was confined at the General Hospital from July 1-6, 1949. He was admitted in a stuporous condition, tremulous, with a history of drinking one quart of whiskey with "all the beer I can hold for the last three months." He had not eaten for the past week. He became more and more incoherent and had hallucinations of bugs crawling on the ceiling and walls. Physical examination revealed a tachycardia, sonorous type of breathing, liver enlarged 2 centimeters below the right costal margin in the medial costal line. He was re-admitted seven days following his discharge, which made the fifth admission because of delirium tremens. At this time the patient agreed to take antabuse treatment. An extensive physical check-up was performed and numerous tests were made with the following results: An electroencephalogram showed low voltage and fast waves; conclusion, borderline electroencephalogram. The basal metabolism rate was minus 20 per cent. An electrocardiogram was within normal limits. The fasting blood sugar was 75 mg. per cent. The glucose tolerance test was performed on two occasions, both showing gross abnormalities. On the first occasion the blood sugar level was 110, after one-half hour 300, after one hour 430, after two hours 150, and after three hours 40. Kidney dilution and concentration test yielded specific gravities varying from 1.001 to 1.030. The PSP test indicated a total of 70 per cent. The blood albumin was 4.09, globulin 2.21. Bromosulfalin test of liver function: "No dye retained." The patient was given 200 mg. of vitamin B_1 and 40 units of insulin on admission because of extreme restlessness, gross tremor and visual hallucinations. At first being quiet, he suddenly jumped out of bed and, then returning to bed, developed a generalized spontaneous convulsion. Following this he was more quiet and expressed no hallucinations. The antabuse treatment was started on July 27 with the usual decreasing doses of antabuse, starting with 2 grams. On the fourth day he was given 40 c.c. of whiskey. He developed mild dyspnea and complained of suffocating. After approximately one-half hour of oxygen, caffeine and insulin had to be administered. The patient developed a very marked fear and anxiety. His pulse became imperceptible and the skin was an ashen gray. The patient stated that he felt as if "the DT's were coming." Oxygen under pressure was administered for twenty minutes and gave good relief. This was repeated twice. The blood sugar then was 150 mg. per cent and the urine was negative for sugar and acetone. Following this occurrence, the patient was put on a cautious daily antabuse dosage of 0.25 gram and was discharged on this dose after a second trial of whiskey, which caused only mild reactions. Though the patient was quite impressed by the reaction of whiskey, he returned to drinking soon after his discharge. He failed to accept follow-up outpatient management.

The following case is reported to illustrate a marked influence on the blood pressure.

Case 4.—B. M., aged thirty-six, a farmer's wife, had drunk to excess periodically since the time she was married to her first husband, from whom she obtained a divorce five years previously. All preliminary clinical and laboratory investigations proved negative, except that her red blood cell count was 3,600,000 and hemoglobin 76 per cent. Besides drinking excessively four months prior to admission to Glenwood Hills Hospital she had taken twelve capsules of 1.5 grains of nembutal daily. A thyroidectomy had been performed in 1946. She was given whiskey at 10:00 a.m. on the fourth day of routine antabuse administration. Her normal blood pressure of 116/72 changed as follows: 10:20, 116/70; 10:30, 102/30; 10:35, 98/28; 10:40, 70/28; 10:45, 84/22; 11:00, 80/30; 11:05, 74/40; 11:30, 78/30; 12:15, 72/42; 12:45, 90/34; 6:00, 120/79. During the first four hours she complained of headache. Two days later whiskey was again administered. One and three-quarters hours later the blood pressure reading was 68/34; the pulse and also breathing continued to be strong. Again a slight headache was complained of for a period of several hours.

Case 5.—M. S., a widow, aged fifty-one, had been a heavy lone drinker for seven years who was started on the antabuse regime three weeks following recovery from her last debauch. No physical nor psychic stigmata were noted until the third day of antabuse administration. Then first signs of memory defect were noted. Antabuse was then discontinued. During the following two weeks it appeared that memory weakness and some degree of reduction in general interests and activity were changing for the better. Antabuse was again prescribed in the amount of 0.5 gram each day. In four or five days there again appeared more signs of psychic deterioration. In the course of the following month without antabuse there has been no change. No signs of peripheral neuritis have been established.

This case is presented because of the suggestion that antabuse might be a factor in hastening central nervous system degeneration. Satisfactory proof that this may be so is lacking. However, the mere suggestion is viewed worthy of future attention.

Results of Treatment

At the time of this writing, the twenty-six patients can be characterized as follows: (1) eleven, no drinking; (2) eight, significant improvement but return to one or more brief bouts of drinking; (3) three, slight improvement; (4) four, no improvement. If we limit our review to the twenty more promising private practice group, we can say that 40 per cent have abstained from drinking and another 40 per cent have done well most of the time. These 80 per cent have lived useful lives socially and economically. Naturally, as more time elapses these figures may change to some degree—probably a reduction of the number in the first group and a corresponding rise in the second, now 40 per cent of the total series. In the small General Hospital group treatment results ended in failure in two-thirds of the six patients, whereas one-third are significantly improved. In the instances when there was a return to drinking, the patients who maintained much sobriety, we can say, alone or more often with the help of the spouse or other relative succeeded in terminating their fling in short order. Patients in this group, as indeed all those taking antabuse, require continued psychotherapeutic care for many, many months.

Antabuse, in the last analysis then does not remove the personality problem from the alcoholic who still must deal with his restlessness and tense inner feelings, particularly at intervals. The deteriorated alcoholic is not a favorable subject for antabuse treatment; the patient with visceral disorder must be rejected lest likelihood of fatal terminations face the therapist. Furthermore, no patient should be accepted for treatment unless he has a convincing willingness and determination to prepare for an ever sober life. With the drug taken in 0.5 gram doses once per day in tablet form, the patient is given an extra handle, so to speak, with which to combat safely the inevitable wavering at some time or another in his future. The therapist can derive deep pleasure when, as happens occasionally, a patient comes to report frankly and proudly that he, though taking his medicine regularly, did want to just try a swig and adds, "Oh, Doc, it didn't taste right, I just did not want any more of it—I guess I will make it."

Summary

Historial notes and experimental work described in the literature, as well as reports on early clinical experiences by Danish physicians concerning tetraethylthiuram disulfide in the treatment of alcoholism, are reviewed. Therapeutic procedures with twenty-six patients are described. Results reported show a significantly higher improvement rate in the treatment of patients in private practice than in those cared for in a public hospital service. The greater incidence of physical and mental deterioration in the latter group served to limit the extent of antabuse treatment. The dangers encountered are described in illustrative case reports; these are reduced effectively by rejection of patients with physical and psychic defects. There were no fatal terminations in this series. The importance of adjunct psychotherapy is stressed.

EMERGENCIES IN THE NEWBORN PERIOD

LLOYD E. HARRIS, M.D.
Rochester, Minnesota

A DISCUSSION of all of the emergencies which might occur during the newborn period is beyond the scope of this paper. The more common problems will be covered briefly. The discussion will be primarily related to the presenting symptom, differential diagnosis, and treatment.

Cyanosis and Abnormal Respiration

Cyanosis is probably the most frequent alarming symptom prompting the nurse in charge to call the physician. The cyanosis is usually associated with some abnormality of respirations. In Table I are listed the conditions one must consider in the differential diagnosis when called to see a newly born cyanotic infant who may or may not have abnormal respirations or who may present abnormal respirations as the primary symptom.

Many newborns may evidence a venostatic type of cyanosis of the face and distal parts of the extremities during the first hours after birth. No treatment is required and clearing is spontaneous.

During the first three days after birth most infants have episodes of vomiting and retching. While retching, the infant may become moderately cyanotic as any of us would do under similar circumstances. There may even be transient convulsive twitchings. These are similar to those seen in an older child in association with a paroxysm of crying following an injury. No treatment is indicated except the turning of the baby face down to avoid aspiration of the vomitus. One is tempted to aspirate the nasopharynx vigorously, but this only stimulates the gag reflex more and accomplishes little. Can you imagine how it would feel to have a large syringe vigorously poked about your throat when you are vomiting?

Before proceeding in the differential diagnosis, one should, as a general rule, administer oxygen continuously to all infants evidencing cyanosis. One may then make every effort to determine the cause of the difficulty. Oxygen may be provided by any one of many methods, ranging from the tube held close to the infant's face to the very elaborate oxygen chambers. We have found a homemade boxlike hood with clear plastic sides to work very well.

TABLE I. CYANOSIS AND ABNORMAL RESPIRATIONS IN THE NEWBORN

A. "Normal" cyanosis of face and extremities
B. "Cyanotic spell" associated with retching
C. Oversedation from anesthesia of delivery
D. Inadequate respirations due to:
  1. Obstruction to airway
    a. Nasal
    b. Nasopharyngeal: tongue, cyst
    c. Laryngeal: lesions of false and true cords, congenital laryngeal stridor
    d. Large bronchi: web, plug
    e. Vascular ring
    f. Tetany
    g. Tracheo-esophageal fistula
  2. Lesions diminishing vital capacity
    a. Atelectasis
    b. Pneumothorax
    c. Pneumomediastinum
    d. Diaphragmatic hernia
    e. Congenital anomalies of lung
    f. Cysts: lung, mediastinum
  3. Neuromuscular disturbance
    a. Cerebral hemorrhage
    b. Massive adrenal hemorrhage
    c. Amytonia congenita
    d. Hematomyelocele
E. Congenital heart disease
  1. Abnormal shunt
  2. Heart block
  3. Paroxysmal tachycardia
  4. Anomalies of coronary arteries
F. Poisoning
  1. Aniline dyes
  2. Nitrites
G. Unexplained: failure to establish adequate respirations

Slow and shallow respirations may occur in the infant if heavy sedation of the mother has been necessary in a complicated delivery. Resuscitation may have been difficult. Oxygen and stimulants such as caffeine sodiobenzoate may be given. The infant should be in a heated crib or incubator.

Cyanosis as a result of inadequate respirations secondary to obstruction of the airway is usually accompanied by suprasternal and infracostal retractions and by inspiratory stridor of some degree. The most frequent cause of this type of respiratory difficulty in the newborn is obstruction of the nares. It is not at all uncommon to see an infant, especially a premature infant, with cyanosis and marked retractions completely relieved by the simple removal of mucous plugs deep in the nares. This cause of respiratory obstruction, though the most common, is very frequently overlooked.

Lesions of the tongue such as idiopathic macroglossia, micrognathia or a cyst of the cecal foramen of the tongue or epiglottis may produce marked obstructive symptoms. Supraglottal obstruction is usually characterized by a coarse in-

---

From the Section on Pediatrics, Mayo Clinic, Rochester, Minnesota. Read at the annual meeting of the Southern Minnesota Medical Association, Mankato, Minnesota, September 11, 1950.

spiratory stridor with a clear cry, and often a diminution or absence of the stridor when the infant is held face down or the tongue and mandible are thrust forward. Lateral roentgenograms of the soft tissue of the cervical region may demonstrate the lesion. Definite diagnosis can usually be made by direct laryngoscopy. Tracheotomy may be necessary as an emergency measure and removal or correction of the obstruction deferred. If one is not prepared to do a tracheotomy, an intratracheal catheter or a small Mosher cannula may be passed until tracheotomy can be done. Oxygen should be given continuously.

Lesions of the true or false vocal cords will produce marked obstructive symptoms and are characterized by a very hoarse cry or aphonia, and by lack of change in the stridor when the position of the infant is altered.

Obstruction of the main bronchi may be due to a thick plug of mucus, or to a congenital web. Physical examination will usually suggest this type of obstruction and a roentgenogram of the chest will substantiate the diagnosis. Primary lobular atelectasis of a degree great enough to cause marked respiratory embarrassment is uncommon. Aspiration of the mucous plug or dilation of the web is usually accomplished by a single bronchoscopic examination.

A vascular ring, tetany or tracheo-esophageal fistula may produce abnormal respirations. Early diagnosis of tracheo-esophageal fistula has become especially desirable since corrective surgical measures have been developed for this anomaly. The diagnosis is usually not made until the infant is offered a feeding, and vomiting follows. There are three points that should make one suspicious of this anomaly even before the infant is offered his first feeding. First, there is usually a rather noisy gurgling type of respiration. Second, the vomiting is not the usual spitting up and retching associated with the expulsion of swallowed air but is a rather continuous "spilling out." Third, the vomitus is clear mucus in contrast to the usual vomitus stained dark with swallowed amniotic fluid, blood and bile. If one is at all suspicious of an esophageal atresia, he may simply attempt to pass a small gavage tube, usually a 10 F. catheter. If obstruction is encountered, then the infant should be examined fluoroscopically and a small amount of radiopaque material instilled through the catheter. Once the diagnosis has been established, an operation should be done as soon as possible, and under no circumstances should anything be offered by mouth. Aspiration pneumonia is the complicating factor in these infants, and every effort should be made to avoid it.

Lesions diminishing the vital capacity may be the cause of cyanosis and abnormal respirations. When infants are examined routinely, it is not unusual to detect a lobar atelectasis which is proved by roentgenogram. There may be very little in the way of respiratory difficulty. Ordinarily these conditions clear up spontaneously in a few days, and bronchoscopic aspiration is rarely indicated unless there is definite respiratory embarrassment. Another type of atelectasis is the diffuse patchy type which may or may not be shown roentgenographically. The only physical finding may be a generally decreased exchange of air accompanied by cyanosis and labored respirations. Bronchoscopic aspiration is of little value in this instance as the obstruction is diffuse and in the smaller bronchioles. Oxygen, feedings by gavage to conserve the infant's energy, and as little manipulation as possible are indicated. Carbon dioxide and oxygen inhalations may be given at intervals primarily to decrease the viscosity of the intrabronchial mucus. They are of questionable value. My colleagues and I have used a saturated solution of potassium iodide at the rate of 3 to 4 drops every three hours for six doses to attempt the liquefaction of the mucus. It is extremely difficult to say whether this has been of real value or not.

Spontaneous pneumothorax may decrease the vital capacity to the extent of respiratory embarrassment and even death. We recently encountered such a case in which immediate withdrawal of air, even before roentgenograms were taken, was a lifesaving procedure. Spontaneous pneumothorax is discovered frequently, as is atelectasis, when physical examinations of the newborn are done routinely. It is only the very rare one that requires aspiration of air. The usual physical findings of hyperresonance, diminution of breath tones and possible displacement of the heart are present. Roentgenograms show the pneumothorax.

Pneumomediastinum may present a difficult diagnostic problem. A fullness of the anterior part of the chest, hyperresonance over the mediastinum, and distant muffled heart tones with fairly marked respiratory distress will suggest the diagnosis. A roentgenogram of the chest in the lateral position will show the air in the anterior mediastinal space. Needle aspiration of the trapped air will give relief.

Diaphragmatic hernia, cysts of the mediastinum and cysts of the lung may diminish the vital capacity enough to cause respiratory embarrassment. The diagnosis is usually made by roentgenogram, and, if indicated, a small amount of barium may be given to discern the location of the stomach. The treatment is usually surgical.

Cyanosis with suppression of respirations and no evident obstructive lesions may be due to intracranial hemorrhage or collapse secondary to a massive adrenal hemorrhage. Our general policy in both diagnostic and therapeutic procedures when intracranial bleeding is suspected is to be guided by the patient's general condition and whether benefit may reasonably be expected from the procedure undertaken. Treatment and diagnosis of intracranial bleeding will be discussed further in relation to the presenting symptom of convulsions.

Congenital heart disease may be the cause of cyanosis. There is usually no respiratory distress associated. A murmur may or may not be present. The cardiac silhouette in the roentgenogram may be abnormal, and the electrocardiogram may be of some assistance. If the cyanotic infant is fairly vigorous, presents no neurologic symptoms and evidences no respiratory distress, one will usually think of a congenital abnormality of the heart. Paroxysmal tachycardia, with a rate of more than 200, and possible hepatomegaly should not be overlooked. A heart rate of less than 60 should suggest heart block, and this will be confirmed by an electrocardiogram. Digitalization may be indicated in the treatment of the paroxysmal tachycardia; there is usually nothing specific to do for the infant with heart block. We have recently observed an infant with complete auriculoventricular dissociation. The heart rate has consistently been between 40 and 50 beats per minute. The infant is now approximately six months old and doing well. Anomalies of the coronary arteries may be the cause of sudden unexplained death in the newborn period.

Poisoning with the aniline dyes occasionally used by the laundry in marking diapers and shirts is mentioned as a rare cause of cyanosis. We in Minnesota are particularly aware of the methemoglobinemia due to an excessive amount of nitrites in the water, although this will rarely be seen during the newborn period.

TABLE II. CONVULSIONS IN THE NEWBORN PERIOD

A. Occasional convulsive twitchings associated with retching and gagging
B. Cerebral edema
C. Intracranial hemorrhage
D. Meningitis
E. Tetany
F. Kernicterus
G. Massive adrenal hemorrhage
H. Toxoplasmosis
I. Unexplained

The last group listed is termed "unexplained." Failure to establish adequate respirations seems at present to state the fact without necessitating a primary diagnosis such as atelectasis. The role of the so-called hyaline membrane as a factor in the failure to establish adequate respirations is certainly open to question. If it is found in as many as 50 per cent of prematures who fail to survive, why isn't it found in the other 50 per cent? How often was it present in that group who survive? Atelectasis is a frequent diagnosis made both clinically and at postmortem examination in premature infants who fail to survive. Atelectasis by definition means imperfect expansion, so this diagnosis is usually correct just as heart failure would be correct in this or any other death. What is the cause of the imperfect expansion? Immaturity does not seem to be a satisfactory explanation in all cases. The problem of the establishment of adequate respiration is the one great primary problem in the care of the premature infant. Feeding, protection from infection and general nursing care are obviously of secondary importance to adequate respirations.

Convulsions

Convulsions occurring during the newborn period usually require emergency attention just as they do at any age period. The causes of convulsions at this age are listed in Table II in descending order of frequency of occurrence.

The "blue spells" discussed previously as occurring during the first few days and associated with gagging and retching are occasionally accompanied by transitory convulsive twitchings of the extremities and facial muscles. No treatment is required and there are no sequellae.

How may one proceed to make a differential diagnosis and then offer treatment when called to see a newborn infant having convulsions? A general evaluation of the infant's condition may give some clues. If it has gray cyanosis, has the appearance of deep shock and is generally flaccid, the lesion is probably a massive intracranial or adrenal hemorrhage. What is the infant's position? An infant with head retracted, arms and legs extended and a staring expression is suggestive of an intracranial lesion. A high-pitched cry much like a short scream and the adder-like protrusion of the tongue are both associated with cortical irritation. Are the convulsions localized to one extremity or one side? Persistent unilateral convulsions suggest the possibility of a subdural hemorrhage. Is there generalized hyperirritability, muscular twitching or carpopedal spasm? These may suggest tetany.

The general physical examination may yield little in the way of positive information. The fontanelle may be bulging and the sutures separated. This finding is rarely present. If opthalmoscopic examination is done by an experienced person, the knowledge of absence of retinal hemorrhages may be of more diagnostic value than their presence. Retinal and subconjunctival hemorrhages are seen in 20 to 30 per cent of all newborn infants. Retinal hemorrhage is often one of the findings in subdural hematoma, so the absence of retinal hemorrhage might aid one in ruling out the presence of a subdural hematoma.

Nuchal rigidity is not a dependable sign in the newborn. The pulmonary exchange may be adequate but shallow and irregular, and slow respirations may be due to intracranial bleeding. The heart tones may be weak and the rate rapid. Abdominal examination usually does not disclose any abnormality but may reveal large masses which might be polycystic kidneys, with secondary uremia and convulsions.

Examination of the extremities for spasticity or flaccidity may be of some help. If there are positive findings, spasticity is usually the more frequent. Evaluation of the deep reflexes may be of some aid, but in the newborn period they are so variable that they often are misleading.

If there is any suggestion that the disease is tetany, one should not hesitate to immediately give calcium gluconate intravenously. If the convulsions are due to hypocalcemia, there will be a rapid response. One does not ordinarily treat a condition blindly but in this case such action seems justifiable. It does not seem wise to wait for the laboratory report on the blood calcium before giving calcium when there is apparently little risk involved in giving the calcium slowly in the absence of hypocalcemia. Our practice has been, when possible, to withdraw blood for determination of the concentration of calcium and then give 4 to 5 c.c. of a 10 per cent solution of calcium gluconate while the needle is in place.

The next decision to make is in regard to lumbar, cisternal, subdural or ventricular puncture. As always, one must ask himself, will this benefit the patient? It does not seem wise to attempt these procedures for the sake of diagnosis only, unless it will be of aid in guiding subsequent therapy. There are some who are quite conservative and feel that lumbar puncture should be done rarely and others who feel that repeated lumbar punctures should be done in cases of intracranial hemorrhage. I personally prefer the more conservative régime and do lumbar punctures as diagnostic procedures or rarely to relieve intracranial pressure when indicated. If difficulty is encountered in doing a lumbar puncture and the urgency of the situation warrants, cisternal puncture may be done. If there are localizing neurologic findings or other symptoms suggestive of subdural bleeding, subdural puncture may easily be done in the newborn. Ventricular puncture may be indicated.

I should like again to emphasize that the positive diagnosis of intracranial hemorrhage in the newborn is not a simple diagnosis to make. The condition is found frequently at postmortem examination when there was no suggestion clinically. The presumptive diagnosis is often made clinically and not substantiated at postmortem examination. This causes one to be extremely cautious in making a positive diagnosis of intracranial bleeding during the newborn period and especially hesitant to attribute subsequent neurologic abnormalities, such as a cerebrospastic palsy, to intracranial bleeding during the newborn period without definite evidence.

Convulsions may be the only symptom suggestive of meningitis at this age. Neurologic symptoms associated with intracranial bleeding are usually manifest within the first day or two of life. Convulsions occurring after this period may more frequently suggest an infectious process. Fever and leukocytosis may or may not be present. A definite diagnosis can usually be made only by examination of the spinal fluid.

Massive adrenal hemorrhage may present a clinical picture similar to that of massive intracranial hemorrhage. Hyperthermia and deep shock are the usual manifestations, and yet recently we have seen an infant with convulsions

THE RANA PIPIENS FROG TEST FOR PREGNANCY

JANE E. HODGSON, M.D., and REIKO TAGUCHI, B.S.
Saint Paul, Minnesota

IN the practice of obstetrics and gynecology, a rapid, simple, accurate office test for pregnancy is extremely desirable. Such criteria will apparently be met by the new *Rana pipiens* frog test, first introduced only two years ago by Wiltberger and Miller[20] and Robbins and Parker.[16,17] During the past six months, I have performed in my office eighty-seven pregnancy tests according to the technique of Cutler,[4] in an attempt to evaluate the accuracy of this test, as well as to aid in clinical diagnosis and treatment. My results have substantiated those of previous writers. As a clinician, I have found it extremely satisfactory, and, compared to the Friedman test, far more rapid, requiring only two to four hours, as compared to forty-eight. It is less expensive and equally reliable, provided its limitations are well recognized and strict adherence to certain technique standards noted. These I will outline briefly, attempting to explain the reasons why certain modifications of the test are of such importance in maintaining a high degree of accuracy.

The principle of the *Rana pipiens* frog test is based upon the Mainini reaction, which was first described by Galli Mainini in 1947.[9] This reaction is the release of sperm in the urine of South American male toads following the injections of gonadotrophic hormones. Injection of pregnancy urine into the male North American frog, *Rana pipiens,* produces the same reaction, provided the level of chorionic gonadotropin is sufficient.

Technique

Adult male frogs are shipped by air from Wisconsin at a reasonable cost. The animals are maintained in a covered enameled pan in an electric refrigerator maintained at a temperature of 10 degrees Centigrade. By this means, the frogs are kept in a state of hibernation and require no food or attention. The bottom of the pan is covered with fresh water, which is changed daily. During the spawning season in the spring and early summer, a spontaneous mortality was rather frequent; but prior to and since that season, the animals have remained in the refrigerator in a healthy state for as long as four weeks at a time. When the urine arrives at the laboratory, the animal is removed from the refrigerator and placed in a beaker to "thaw out" for thirty minutes prior to injection. The Scott kaolin adsorption method[4] of concentration of urine is used. This technique of urine concentration is a relatively simple procedure which can be performed by any qualified laboratory technician. No elaborate equipment is required, and it does not consume over thirty minutes. Sex of the frog should be carefully noted. The male is distinguished by large pigmented thumbs, inflated air sacs and croaking (Fig. 1). One c.c. of the final product is injected into the dorsal lymph sac of the frog (Fig. 2). The animal is then replaced in the beaker. After thirty minutes, the frog's urine is obtained upon a slide, and a drop examined for sperm (Fig. 3). A positive response usually appears within thirty to forty minutes after injection, never later than three hours. There are usually large numbers of sperm actively motile and easily recognized under low or high dry magnification. The sperm of *Rana pipiens* are considerably larger than human sperm. Their heads are cylindrical or cigar-shaped. Absence of sperm for three hours constitutes a negative test. Animals showing negative responses may be reused after three to four days, but should be promptly returned to the refrigerator in the interim. Animals showing positive responses are destroyed.

Discussion

Chorionic gonadotropin appears in the urine of pregnant women a few days following implantation of the ovum between the twenty-second to the twenty-fifth cycle days. By cycle days, we refer to the number of days following the last menstrual period. By the thirty-second cycle day, chorionic gonadotropin has risen to 200 to 500 rat units per liter. It is at this point that hormonal pregnancy tests may become positive. The earliest positive frog test reported occurred on the thirty-fourth cycle day. Our earliest positive reaction was noted on the thirty-fifth cycle day. Chorionic gonadotropin excretion rapidly rises thereafter to reach a peak between the fifty-second to the sixty-fifth day of 133,000 to 400,000 rat units per liter. After the sixty-seventh day, the excretion of

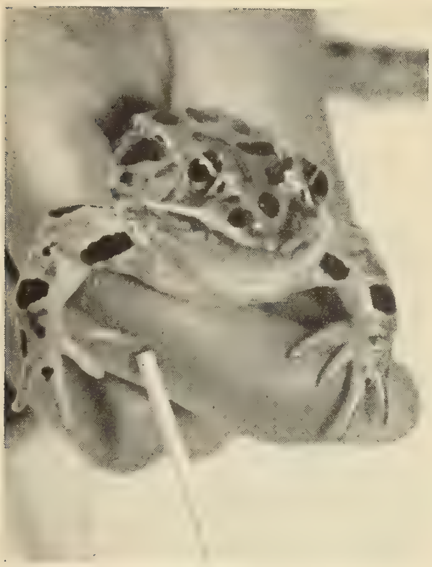

Fig. 1. Male frog is distinguished by large pigmented thumbs and air sac.

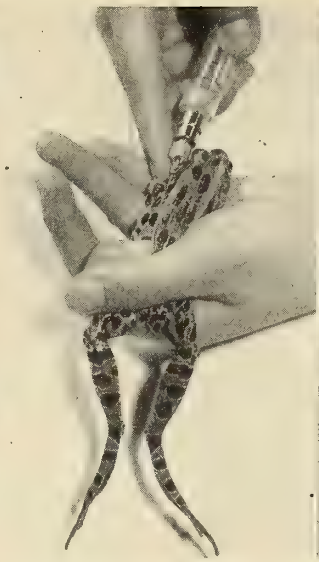

Fig. 2. One c.c. hormonal concentrate is injected into dorsal lymph sac of frog. Injection should be made just beneath the skin. Care should be taken not to puncture the lung.

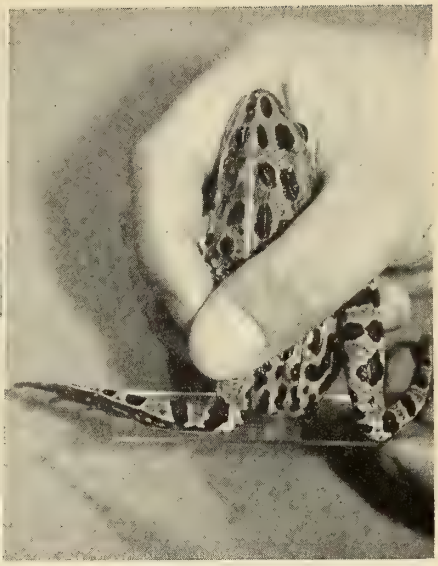

Fig. 3. Frog's urine is obtained upon a slide by flexion of legs.

chorionic gonadotropin drops sharply, reaching low levels around the sixth month, rising slowly again towards the end of pregnancy. Inasmuch as the positivity of this test is dependent upon there being a certain amount of chorionic gonadotropin in the injected urine, probably around 10 rat units, a positive response cannot be obtained with certainty before the fourth week of pregnancy (forty-second cycle day). Therefore no negative test should be accepted before the forty-second cycle day. However, a positive response is dependable at any time of gestation, inasmuch as we know of no condition under which false positives occur. Physiologically in the frog it is the luteinizing hormone secreted by the anterior pituitary gland which produces the release of sperm. Follicle stimulating hormone does not have this effect. The fact that follicle stimulating hormone does not release the sperm gives the frog test a definite advantage over the Friedman test, inasmuch as false positive reactions are eliminated in testing menopausal urines. The Friedman test does not have this advantage. False positive Friedman tests are frequently noted in the menopause, due to the large amount of follicle stimulating hormone in menopausal urine which produces follicle formation in the rabbit.

Another big advantage of the male frog pregnancy test is the rapidity with which the response becomes negative after the separation of the chorionic villi when abortion becomes inevitable. This fact was pointed out by Wiltberger and Miller, who state that the male frog test becomes negative ten to twelve hours after the termination of pregnancy. In four threatened abortion cases, we noted a change in response from positive to negative even *before* the abortion was completed. With the Friedman test, a positive reaction may persist seven to ten days after pregnancy is terminated.

Results

Mainini utilized his reaction in the detection of pregnancy by injecting 10 c.c. of whole urine into South American toads and examining their cloacal specimens for sperm. In over 2,000 tests, he reported no false positives and an accuracy of 99.01 per cent through the fifth month of pregnancy. Shortly after Mainini's report, two articles appeared in this country by Wiltberger and Miller[20] and Robbins and Parker.[16,17] These workers substituted the North American frog, *Rana pipiens,* with equally good results. The North American toad, the British toad, and British frog, *Rana esculenta,* have also been reported as being entirely satisfactory animals for this test. Since the first article in 1948, a number of laboratories have reported their experiences with the *Rana pipiens* test. There is a wide variation in technique among the different authors.

All agree as to the absence of false positive reactions. The accuracy of this test is reported as being extremely high by all but three writers[2,10,18] who report a rather large number of false negatives. It is noted in their articles that unconcentrated urine was used and in small amounts, that all stages of gestation were included in their final figures, that the frogs were not refrigerated and were re-used. As stated previously, this is a test for the presence of chorionic gonadotropin in the urine, and there is a definite threshold at which the test becomes positive. Obviously, the incidence of false negative responses will be lower in those laboratories where the urine was concentrated or where larger amounts of urine were injected and when pregnancy urine in the first trimester only was tested. Improved results are also noted where the animals are not re-used, at least those animals which have previously shown positive responses. One is prohibited from using large doses of whole urine because of the high frog mortality which results. Use of the Scott kaolin adsorption method allows for the injection of the hormonal content of 20 c.c. of urine by injecting only 1 c.c. of detoxified hormonal concentrate. In only three reports of the *Rana pipiens* test to date has concentrated urine been used, and in these reports, the results have been extremely encouraging (Cutler,[4] Brody,[3] Maier[13]). Our results with the urine concentrate confirm the work of these writers. In performing our tests, we have followed closely the technique of Cutler. He reported a 99 per cent accuracy and no false positives in 200 cases. His two false negatives resulted from the re-use of frogs. After discontinuing the re-use of frogs which have previously shown positive reactions, there were no more false negative responses. In our eighty-seven consecutive tests performed to date to aid in the diagnosis and treatment of difficult clinical problems, there were two false negatives. One test was performed before the fourth week of pregnancy, and the specific gravity of the urine was less than 1.010. Only one animal was used in this test. We have since instituted the policy that all negative responses must be corroborated by the use of two frogs. Our second false negative was a test performed upon a woman on her supposedly fifty-seventh cycle day. A repeat test one week later was positive. This patient gave a history of recurrent episodes of amenorrhea, and it is possible that the first test was performed actually earlier in gestation than the fifty-seventh cycle day would indicate. Moreover, only one frog was used in the first test. The policy which we have arrived at to eliminate as many false negative responses as possible and yet to conserve our technician's time and our laboratory animals are as follows:

Two and one-half c.c. of filtered whole urine are injected into one frog. The urine must be a morning specimen with specific gravity of at least 1.010, providing there are 100 c.c. If the volume of urine is less than 100 c.c., a specific gravity of 1.015 is necessary. If the response is positive, the test is completed, usually within one to two hours. If the test is negative after three hours, the urine is then concentrated and injected into two additional animals. If the response is still negative but less than two weeks have elapsed since the patient's last menstrual period (less than the forty-second cycle day), the test is repeated in one week. A negative response should never be accepted before the forty-second cycle day.

Summary

I have found the *Rana pipiens* frog test for pregnancy an excellent and indispensable aid in clinical practice. The work of Cutler, Brody and Maier has been herewith confirmed. In the performance of the test, I should like to stress the importance of meeting the following criteria:

1. Refrigeration of healthy frogs.
2. Careful differentiation as to sex.
3. Duplication of animals (at least in negative responses).
4. No re-use of animals that have shown positive responses.
5. Morning urine specimens of no less than 1.010 specific gravity.
6. Concentration and detoxification of urine (Scott kaolin adsorption method).
7. Non-acceptance of negative responses before the forty-second cycle day.

ACUTE YELLOW ATROPHY OF THE LIVER FROM SH VIRUS TRANSMITTED BY A BLOOD BANK

WINSTON R. MILLER, M.D., R. V. SHERMAN, M.D., and G. N. HOFFMAN, M.D.
Red Wing, Minnesota

THE condition formerly referred to as acute catarrhal jaundice was clarified during the war as a virus disease which occurs in two closely similar forms: (1) the naturally occuring epidemic or sporadic hepatitis, and (2) the artificially produced serum hepatitis (commonly called homologous serum jaundice).[4] The chief differences in the two forms lie in the mode of transmission and the incubation period. Serum hepatitis is transmitted by parenteral injections of blood, plasma or biological products containing human serum, or by improperly sterilized syringes, needles or medications.[7,8,9] The incubation period of sixty to 160 days is in marked contrast to the ten to forty day incubation period of sporadic or epidemic hepatitis. Tests with human volunteers have shown that specific immunity develops after infection and there is no cross protection between the two forms of the disease.[3,5] These tests have also shown that as little as 0.01 c.c. of serum from a case of serum hepatitis contains sufficient SH virus to transmit the disease.[4]

Clinically and pathologically, serum hepatitis and sporadic or epidemic hepatitis are almost indistinguishable after the onset of the disease. There are two anatomical (or rather histological) types of infectious hepatitis: (1) the hepatocellular type, and (2) the periacinar or cholangiolitic type.[10] Both types occur equally from the sporadic and epidemic virus (IH virus) and from the serum virus (SH virus). In the hepatocellular type the dominant pathological change is a degeneration of the liver cells. Fulminating cases of infectious hepatitis are usually of this type and show extensive diffuse necrosis of the liver cells[9] —the picture of acute yellow atrophy of the liver. In the cholangiolitic type, described in detail by Watson and Hoffbauer,[10] there is an intense inflammatory reaction around the bile ducts with intrahepatic biliary obstruction, and only transient involvement of the liver cells. Severe cases of this type progress to an hypertrophic (Hanots) or sometimes atrophic (Laennec's) biliary cirrhosis, with prolonged regurgitation jaundice.[10]

The combined results of a number of liver function tests gives an accurate differential diagnosis between the hepatocellular type of infectious hepatitis and extrahepatic biliary obstructive jaundice due to stones or carcinoma.[4] However, in the pure cholangiolitic type of infectious hepatitis, the liver function tests may show only the picture of obstructive jaundice, and the differential from extrahepatic biliary obstruction can be made only by laparotomy in some cases.[10] The decision to explore the extrahepatic biliary tract is of great importance since it is well known that surgery has a deleterious effect on infectious hepatitis.

A patient suffering from pulmonary tuberculosis developed a severe serum hepatitis with a combination of the cholangiolitic and hepatocellular types of pathological change.

Case Report

A. B. J., a man, aged twenty-seven, was admitted to the Mineral Springs Sanatorium, Cannon Falls, Minn., December 21, 1943, because of hemoptysis on December 15, 1943. He had had a moderately productive cough and had lost 10 pounds in weight in the past six months. Chest films showed soft infiltration between the first and third ribs on the right. The diagnosis was moderately advanced pulmonary tuberculosis, active. Cultures and guinea pig inoculation of gastric washings were positive. The patient left the sanatorium against advice on December 24, 1943, and refused to return even when he was told of the positive cultures. He continued to live with his wife and two small children and resumed his regular occupation.

The patient was admitted the second time to Mineral Springs Sanatorium on November 24, 1945. Chest x-ray showed soft infiltration had spread to most of the right lung and to the fourth interspace on the left. There was cavitation in the apex of the right lung. He was treated with pneumothorax, pneumolysis, phrenic crush and later oleothorax and pneumoperitoneum. He left the sanatorium a second time against advice on April 1, 1947. Within a few months he was back at full-time work. He did continue pneumoperitoneum refills.

The patient was admitted the third time to Mineral Springs Sanatorium on August 3, 1949, after having more hemoptysis. Sputum smears were positive and x-ray showed further progression in the right upper lobe with increase in the cavitation. He was transferred to Colonial Hospital in Rochester, Minnesota, where a right upper and middle lobectomy was performed on September 23, 1949. Four 500 c.c. bottles of blood from the

---

Read at the annual meeting of the Southern Minnesota Medical Association, Mankato, Minnesota, September 11, 1950.

blood bank were given during the operation. One additional pint of blood from the bank was given on September 24, 1949. No plasma or human serum products were given. He was treated also with streptomycin and para-aminosalicylic acid. A one-stage thoracoplasty was performed at Mineral Springs Sanatorium on October 12, 1949. He received one pint of blood during the operation, another on October 14, and another on November 15. Recovery from the operation was rapid and uneventful. He left the sanatorium against advice for the third time on December 5, 1949.

The patient (now aged thirty-three) was admitted to St. John's Hospital in Red Wing, Minnesota, on December 15, 1949, with complaints of nausea, vomiting and jaundice. He reported he noticed nausea first on November 25, 1949, but did not vomit. He had anorexia and occasional nausea between November 25 and December 10. On December 10 he had nausea and vomiting, and he noted a slight yellow color to the skin. On December 12 he noted clay-colored stools and dark urine. He had no pain and no chills or fever.

Physical examination on admission showed a thin, white male with moderately severe jaundice. Temperature, pulse, respiration and blood pressure were normal. Examination of the chest showed a partial collapse of the right chest with relative dullness and absent breath sounds in the apex. The chest was otherwise negative. The heart was normal in size and rhythm, but was shifted slightly to the right. The liver was palpable two fingers below the costal margin in the mid-clavicular line and was firm and non-tender. It did not move with respiration due to right phrenicotomy. The remainder of the physical examination was unremarkable.

Laboratory examinations are shown in Table I. Diagnostic duodenal drainage showed no bile in the first specimen, 1+ test for bile thirty minutes after one ounce of magnesium sulfate and 2+ test for bile thirty minutes after a second ounce of magnesium sulfate.

TABLE I. RESULTS OF LABORATORY EXAMINATIONS

		Day of Disease						
	Normal	7	13	14	21	27	31	38
Hemoglobin	14.5 gm.	13.2					11.2	Expired
Urinalysis		neg.					neg.	
Icteric index	4-6 u.		150	224	277			
Cephalin floculation	0	3+			3+			
Thymol turbidity	0-4 u.		20		76		100	
Prothrombin %	100		67					
Plasma protein	6.4-8%			6				
A/G ratio	1.5-2.0			1.14				
Quantitative fecal urobilinogen	100-150 mg.					3.5		
Bleeding time	1-3 min.						1.5	
Coagulation time	1-7 min.						3.5	

Clinical Course.—From the onset of definite symptoms (December 10) until death (January 16) the patient had completely acholic stools. He was treated with a high protein high carbohydrate diet (P 100, C 250, F 80), 1 to 2 liters of 10 per cent glucose intravenously daily, therapeutic vitamins orally and intravenously, methionine 4 grams daily, crude liver extract 2 to 4 c.c. intramuscularly daily, crude liver intravenously later, vitamin K parenterally, and choline chloride orally for a short time.

For the first two weeks in the hospital treatment was effectively administered, and his general condition was only a little worse than it was at the onset. He took the full diet and medications and in spite of frequent nausea he did not vomit. He was even able to go home to be with his family on Christmas day. From December 28 on, his course was more rapidly downhill, and severe anorexia, nausea, and occasional vomiting made diet and oral medication much less adequate. Jaundice became progressively more intense and anorexia became so severe the patient had to literally force the food down. At no time was the temperature above 98.6° and there was no pruritis. The liver regressed in size until the edge was above the rib margin. Hepatic fetor developed and increased progressively. With the fecal urobilinogen and clinical evidence of complete biliary obstruction persisting after thirty days, faith in our own convictions waned and exploratory laparotomy was performed on January 10, 1950, for a possible complicating extrahepatic biliary obstruction. The extrahepatic biliary passages were collapsed but patent. The liver was slightly smaller than normal and showed a blotchy yellow nutmeg appearance. A biopsy was reported by the hospital pathologist, Dr. Noble, as follows: "Section of biopsy of the liver shows the liver lobules to be encompassed by thin bands of fibrous connective tissue. There is a dense peri-cholangitic reaction. Conclusions: cirrhosis of the liver." For the next four days the patient seemed to improve slightly. On January 15, 1950, he became severely agitated, lost contact with reality and later in the day lapsed into a comatose state. The coma persisted and on January 16, 1950, he died.

Autopsy.—General Observations: The body is that of a thirty-three-year-old, thin, white, male, about 70 inches long and weighing about 120 pounds. The skin has a deep yellowish brown color. There are recent scars of the right rib resection and right upper quadrant laparotomy, and old scars from right phrenecotomy and multiple pneumoperitoneum punctures. The peritoneal cavity contains only about 200 c.c. of clear yellow fluid. All organs and relationships are normal. The liver edge is about two fingers above the costal margin. The thoracic cavity shows about 100 c.c. of yellow clear fluid in each pleural space. The right chest cavity is collapsed in the upper portion and the upper five ribs have been removed. The right parietal pleura is very thick in the apex. Cut section measures 1 centimeter and consists of thick fibrous tissue with diffuse calcium deposits. Only the right lower lobe remains and this has assumed a semi-conical shape but does not ascend to the apex of the thoracic cavity. The heart is shifted slightly to the right. The left lung relationships are normal. There are many scattered adhesions in the apex and posteriorly.

Organs: Cut sections of the left lung show only dependent posterior congestion. The right lower lobe is a dark, dirty brown color and has a solid consistency. Crepitation is moderately reduced. Cut section shows marked diffuse fibrosis. A small amount of serous mucoid secretion is present in the cut section. No nodules or caseation necrosis is seen. The right hilar nodes are surgically absent. The left hilar and mediastinal nodes are enlarged and fibrous in character.

The liver is about half normal size and is quite firm. The surface is smooth and there are no adhesions. The organ is deeply yellow in color and shows an exaggerated mottling or nutmeg appearance. Cut section shows extensive fibrosis and complete distortion of the normal architecture with a marked nutmeg appearance.

The gall bladder is thin walled and contains a small amount of thick greenish brown bile. The bile ducts are intact and are patent throughout. The ampulla of Vater is completely normal in appearance.

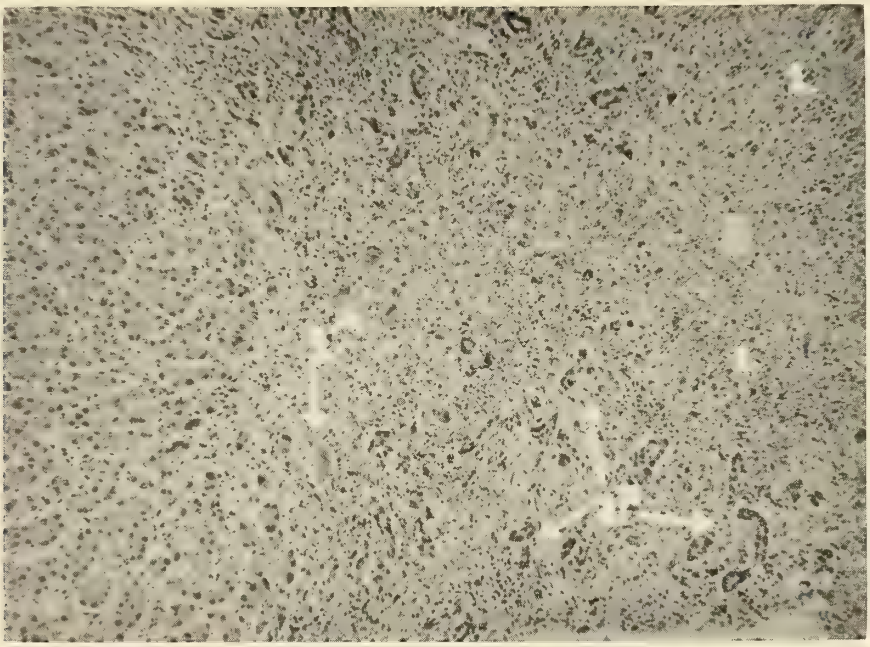

Fig. 1. Photomicrograph of the periphery of a typical liver lobule. Note (1) the intense pericholangiolitic inflammatory reaction with round cell infiltration and fibroblastic proliferation, (2) the marked regeneration of bile ducts, and (3) the liver cell necrosis and large multinucleated liver cell regeneration.

The remainder of the organs are normal or show the usual postmortem changes.

The gross anatomical diagnoses are: (1) acute yellow atrophy of the liver, (2) diffuse pulmonary fibrosis of the remaining right lower lobe.

Microscopic Pathological Changes: The significant microscopic pathological changes are limited to the right lung and the liver. The lower lobe of the right lung shows many small tuberculous lesions with the typical microscopic characteristics. No cavitation is present.

The liver shows extensive destruction of the normal architecture (Fig. 1). There is a great deal of degeneration and frank necrosis of the liver cords. In many areas, however, there are multiple foci of large multinucleated regenerating liver cells. There is an intense pericholangitic inflammatory reaction with fibrosis and round cell infiltration. The bile ducts are patent and the epithelium shows little change. Many minute regenerating bile ducts are present indicating a considerable attempt at regeneration of the intrahepatic biliary system. Only occasional biliary thrombi are seen.

The microscopic diagnoses are: (1) subacute hepatitis with necrosis of liver cells and regeneration of bile ducts, (2) caseous pulmonary tuberculosis.

Comment

At the time of onset this case was similar to most cases of serum hepatitis with combined cholangiolitic and hepatocellular involvement. The incubation period, if figured from the first five transfusions until the onset of definite symptoms, was seventy-nine days. If it is figured from the second group of two transfusions it was fifty-seven to fifty-nine days. Since the patient received no plasma or serum preparations and the mode of onset and clinical manifestation were typical of serum hepatitis, it was concluded that he undoubtedly received the SH virus from one of the blood donors. All the donors had denied a history of jaundice when the blood was donated. It is therefore probable that one of the donors either was in the incubation period of serum hepatitis or was a chronic carrier of the virus after a non-icteric serum hepatitis infection. Until tests are devised to detect the virus in the blood of persons who are otherwise well, this type of accidental transmission of serum hepatitis is unavoidable. Current methods of sterilizing plasma with 2537 Å unit ultraviolet irradiation cannot be applied to whole blood.

For the first three weeks of illness the cholangiolitic type reaction was dominant with complete intrahepatic biliary obstruction and only moderate hepatic cellular involvement. This was indicated by the clinical course, the return of prothrombin function to normal and the liver biopsy showing the intense periacinar reaction. From then on, however, the course was that of severe hepatic necrosis and the patient had a typical hepatic death.

This case represents a combination of the two histological types of infectious hepatitis—first, the intense cholangiolitic reaction with persistent complete intrahepatic biliary obstruction, and second, the hepatocellular degeneration with extensive necrosis, atrophy, hepatic fetor and hepatic death.

Summary

A case of serum hepatitis transmitted by a blood bank is presented. The patient showed a predominant cholangiolitic hepatitis with complete intrahepatic biliary obstruction and early biliary cirrhosis, and then developed marked hepatocellular degeneration and died with the characteristics of acute yellow artrophy of the liver.

The authors are indebted to Dr. J. R. McDonald of the Mayo Clinic for the microscopic pathological studies and for the photomicrograph of the liver.

EMERGENCIES IN THE NEWBORN PERIOD

(Continued from Page 1207)

and hyperthermia but no shock until a few minutes before death. Massive adrenal hemorrhage was the only positive finding at postmortem examination.

Convulsions may also be evidence of a kernicterus developing in an infant with erythroblastosis fetalis. Convulsions with evidence of hydrocephalus or microcephalus may suggest toxoplasmosis.

There are many other conditions during this period of life which require immediate action: atresias of the bowel, a large omphalocele, imperforate anus and other anomalies requiring surgical treatment should be operated upon as soon as possible. Surgical procedures are best tolerated in the newborn if done within the first twelve to eighteen hours after birth. Birth paralyses, congenital dislocation of the hip, clubfeet and metatarsus varus of severe degree will all benefit by treatment instituted during the newborn period. It is not within the scope of this paper to discuss vomiting, diarrhea, infections, abnormalities of the blood and other illnesses of the newborn period.

Summary

Emergencies arising during the newborn period and manifested by cyanosis or abnormal respirations, or both, and those associated with convulsions are discussed in respect to differential diagnosis and treatment.

PRACTICAL CONSIDERATIONS IN THE DIAGNOSIS AND TREATMENT OF ECTOPIC PREGNANCY

CHARLES H. McKENZIE, M.D., F.A.C.S.
Minneapolis, Minnesota

ECTOPIC pregnancy is a gestation in which the fertilized ovum implants itself in some other site than the usual endometrium. The incidence is about four ectopic pregnancies for every 1,000 live births. An ectopic pregnancy, by definition, may occur in a tube, ovary, abdomen, rudimentary uterine horn or endometriotic pocket, and in a tube after hysterectomy.

There are many conjectures as to the cause of ectopic pregnancy. It is noteworthy, however, that in the majority of cases there is a history of sterility and previous pelvic infection involving pelvic operation or appendectomy.

Diagnosis

A woman in the childbearing age who after an anomalous menstrual period has a sudden sharp pain in the lower abdomen, often accompanied by a feeling of fainting, and who on examination has a tender cervix and a tender adnexal mass, most often presents the picture of an ectopic pregnancy rupturing at its commonest site, the outer third of the tube.

Unfortunately the symptoms of ectopic pregnancy vary with the site of implantation, and the classical picture may have all the fuzziness of modern art and be as difficult of interpretation as a surrealist painting. In a series of 1732 collected cases, only 63 per cent were diagnosed correctly preoperatively.

With the classical picture as a background we might attempt to consider the diagnosis of ectopic pregnancy of three types: (1) the explosive type, (2) the unruptured ectopic, and (3) the atypical ectopic.

The Explosive Type.—Occasionally the first intimation of an ectopic pregnancy is massive intra-abdominal hemorrhage, which comes on so suddenly that the site of hemorrhage cannot be determined. Generalized abdominal tenderness, rigidity, rebound tenderness, increasing shock, may simulate a perforated ulcer, mesentric thrombosis, splenic rupture. Clues to the site of hemorrhage may be the gradual development of shoulder-strap pain and the bulging cul-de-sac. In general, the nearer the uterus, the more explosive the rupture of ectopic pregnancy. An interstitial pregnancy may rupture with fatal massive hemorrhage even before a missed or anomalous period.

First, one should treat the shock. Glucose, saline, plasma and blood may all be used intravenously in arms and legs. As soon as the patient is recovering from shock, then emergency abdominal operation preferably under local infiltration anesthesia supplemented when necessary by pentothal, is indicated to find and ligate the source of the hemorrhage.

Unruptured Ectopic Pregnancy.—About 10 per cent of ectopic tubal pregnancies are diagnosed before rupture. The following signs and symptoms are suggestive of unruptured ectopic tubal pregnancy. A woman in childbearing age who has been sterile for some years misses a period and begins to have nausea and engorging breasts. On pelvic examination the uterus is found softened and enlarged and a pelvic mass is found in one adnexa. The Friedman test is positive. Culdoscopy shows enlarged engorged uterine tube.

There is no expectant treatment for unruptured ectopic pregnancy.

Atypical Ectopic Pregnancy.—All too frequently the correct interpretation of the symptoms and signs requires all one's diagnostic acumen and hunch. It has been estimated that 15 to 30 per cent of ectopic pregnancies are so atypical in symptoms and signs that a correct diagnosis is not made preoperatively. The different sites of implantation, the varying amounts of intra-abdominal bleeding, survival or death of the fetus—all tend to produce bizarre findings which, in such atypical cases, may persist or may vary over days, weeks or months.

I. Symptoms

1. Bleeding.—Uterine bleeding follows a few days after an early period and recurs with crampy lower abdominal pains.

2. Pain.—Lower abdominal unilateral pain, usually crampy, is often the first complaint. Sometimes however, the pain shifts to various quadrants with varying posi-

---

Read at the annual meeting of the Southern Minnesota Medical Association, Mankato, Minnesota, September 11, 1950.

tions of the patient and may simulate gall-bladder colic, perforated ulcer pain, or produce the inspiratory "grunt" of basal pneumonia.

II. Signs

1. Ileus.—Slight to moderate ileus is almost invariably present and is frequently overlooked.

2. Abdomen.—Abdominal tenderness, usually in the lower abdomen, varies with the amount and activity of bleeding and the position of the patient.

3. Pelvic Examination.—When present, the excruciating tenderness of the cervix is diagnostic, but the rupture may be so old that little tenderness is elicited. A unilateral tender mass may be found but the enlarged corpus luteum of early pregnancy—tingling breasts, nausea, frequency—suggest gestation but do not locate it.

Differential Diagnosis

In arriving at a diagnosis of ectopic pregnancy one should consider the following: (1) abortion, in progress or incomplete, (2) salpingitis, (3) appendicitis, (4) ruptured or bleeding corpus luteum cyst or ovarian follicle, (5) ovarian cyst with torsion of pedicle, (6) endometriosis, (7) gall-bladder colic, (8) pleurisy, (9) perforated peptic ulcer, and (10) any abdominal emergency.

Since "commonest things are still commonest," and abortion results in one out of every four or five conceptions, one must consider abortion as the most likely probability.

	Abortion	*Ectopic Pregnancy*
Onset of pain:	Gradual	Sudden, often with fainting
Site:	Generalized lower abdominal pain	Severe and unilateral
Bleeding:	Profuse and external	Slight external
Shock:	Proportional to blood loss	Out of proportion to external bleeding

	Appendicitis	*Ectopic Pregnancy*
Onset:	Sudden	Nausea and vomiting, if present, have been for sometime and are typical of pregnancy
Other signs of pregnancy:	None	Present
Tenderness:	At McBurney's point	Lower abdomen
Pelvic findings:	Minimal	Tenderness

III. Other Diagnostic Aids

Temperature, pulse, blood pressure, white blood count and sedimentation rate may be of value but are all equivocal in atypical ectopic pregnancy.

Pregnancy tests, if positive, are helpful.

Spectroscopic demonstration of hematin in the patient's serum denotes blood in a serous cavity.

Endometrial biopsy, or curettage, which reveals chorionic villi, shows that the pregnancy is or was intrauterine; but when the fetus in an extra-uterine pregnancy dies, the endometrium may show almost any picture.

Cul-de-sac puncture which reveals free blood is diagnostic, and usually, only confirmatory.

Culdoscopy, a relatively simple procedure, is of real value in the diagnosis of atypical ectopic pregnancy, enabling one to visualize the tubes, ovaries, and blood if present.

Points in Treatment

It is advisable not to operate until shock is under control or is being controlled.

Local anesthesia, supplemented with pentothal if necessary, is usually preferable.

The whole tube should be removed, for stumps of tubes tend to be the sites of recurrent ectopics.

Auto-transfusion using the blood found in the abdomen is not very feasible. Its use should be attempted when no other blood is available.

Concomitant operations, such as appendectomy, are usually desirable, depending, however, on the condition of the patient. Such additional surgery apparently does not add to morbidity or mortality.

COMMON INJURIES OF THE KNEE JOINT

EDWARD D. HENDERSON, M.D.
Rochester, Minnesota

WATSON-JONES made the statement that the most important single factor in the successful treatment of all knee injuries is the maintenance of good quadriceps tone and power. In addition to this might be added the paramount importance of early and accurate diagnosis. If the exact nature and extent of the injury is ascertained, it is usually possible to apply rational treatment at an early time. The aim of treatment of all injuries to the knee not involving fractures is to avoid a weak and unstable knee. The function of stability is that of the four principal ligaments of the joint plus the quadriceps mechanism.

The quadriceps mechanism consists of the four anterior muscles of the thigh converging into the patella and through an aponeurosis on either side into the patellar tendon. It not only provides the power of extension for the knee but also is an important factor in the stability while in active motion and weight bearing.

The four principal ligaments from the functional standpoint are the two collateral ligaments, medial and lateral, and the anterior and posterior cruciate ligaments. The collateral ligaments prevent abduction and adduction of the knee and are most efficient when the knee is fully extended. Testing for the continuity of these ligaments should be done only with the knee fully extended. The anterior cruciate ligament prevents forward displacement of the tibia on the femur, while the posterior cruciate ligament prevents backward displacement of the tibia. These functions should be tested with the knee flexed to 90 degrees. The first procedure which should be done when confronted with the problem of diagnosis in cases of acute injury of the knee is to secure good anteroposterior and lateral roentgenograms of the knee joint. Special views such as oblique, intercondylar notch, or special patellar views may be necessary to rule out fractures absolutely. If a fracture is not present, it may not be possible to determine for the first twenty-four hours the exact extent of the injury to the joint.[1] If there is any doubt, it seems the best policy to put the patient to bed with the affected leg elevated and to apply ice to the knee joint to reduce as much as possible the edema and hemorrhage. It is thus essential to test carefully all the ligamentous functions which have been described. If there is real doubt because of a low pain threshold or other reasons, it may be necessary to anesthetize the patient to determine whether the ligaments are intact.

A contusion, with or without traumatic synovitis and hemarthrosis, is the least serious of injuries to the joint. If no swelling occurs and if ligamentous stability is normal, the injury is minimal, but even in this case the patient must be observed closely and the preservation of good quadriceps tone and power must be maintained by exercise to ensure prompt recovery and avoidance of later disability due to instability.

If swelling of the joint occurs within an hour, hemorrhage into the joint or surrounding tissues is present. If the fluid is intra-articular, it will be possible to palpate a fluid wave. If blood is present in the joint, it should be aspirated and a tight pressure dressing should be applied to prevent further hemorrhage.

On the other hand, if swelling does not occur until several hours after the injury, the fluid is an effusion due to traumatic synovitis. In this case, aspiration should not be carried out, but the joint should be wrapped with a pressure dressing and quadriceps exercises should be begun immediately.

More serious injuries to the knee joint, excluding fractures, involve the collateral or cruciate ligaments and the menisci or semilunar cartilages. Perhaps the most frequently injured ligament is the medial collateral ligament. This ligament is injured by a blow on the lateral side of the knee or by any other force which tends to abduct the joint.[4] Football is the sport most prolific in the production of such injuries. The severity of the ligamentous damage varies from a simple sprain, with tearing of a few fibers but with normal lateral stability, to complete rupture of the ligament with excessive lateral mobility of the joint. If a sprain is diagnosed, the treatment should be conservative. Protection of the ligament by a tight bandage and by raising of the

---

Dr. Henderson is Assistant to the staff, Section on Orthopedic Surgery, Mayo Clinic, Rochester, Minnesota.

Read at the annual meeting of the Southern Minnesota Medical Association, Mankato, Minnesota, September 11, 1950.

inner border of the heel is considered adequate. The importance of early institution of quadriceps and other nonweight-bearing exercises cannot be overstressed.

If there is a complete rupture of the ligament, either plaster immobilization or early operation with surgical suture of the ruptured ligament and inspection of other joint structures should be used. Watson-Jones favored a two or three months' trial of conservative therapy, but most American authors favor early operation for several reasons. One of these is that repair of the ligament is much easier soon after injury. Secondly, it is possible to inspect the joint to find torn menisci and remove them if indicated.

The same principles of treatment apply to injuries to the lateral collateral ligament and to those of the cruciate ligaments. If fracture of the tibial spine occurs with clinical evidence of rupture of the anterior cruciate ligament, an open reduction should be performed. This injury should be regarded as an avulsion of the anterior cruciate ligament at its attachment to the tibia.

Whereas injuries of the collateral ligament occur by application of lateral force on the extended knee, injuries of the menisci occur when weight-bearing rotation forces are applied to the flexed knee, as when a halfback pivots sharply on one leg to avoid a tackler. Medial meniscus tears are several times commoner than those of the lateral meniscus, but the latter are not as rare as had been the common conception several years ago.[2,3] There are two types of meniscus tears. The first is the longitudinal or "bucket handle" tear, and the second is the transverse tear in the posterior horn. The classic sign of the "bucket handle" tear is locking, or inability to extend the knee fully. In addition, there is usually swelling of the knee with pain over the involved meniscus. There may also be a history of sudden "unlocking" with or without manipulation. If it is the first locking, conservative treatment by manipulation, traction or splinting with active quadriceps exercises is in order. However, if repeated locking occurs, the offending meniscus should be excised surgically. The often held misconception that removal of menisci is often followed by a stiff knee is, fortunately, not true, especially if proper attention is paid to exercising the quadriceps mechanism.

Posterior horn tears of either meniscus are more difficult to evaluate. There is no locking but only an uneasy feeling of instability and fear that the knee might lock. The MacMurray sign, that is, the elicitation of a click by rotation of the tibia in the extreme flexed position, is the only reliable sign, but is not always present. Surgical excision of the meniscus is the treatment of choice.

In conclusion, it may be stated that the common ligamentous injuries of the knee joint should be treated according to the structure affected and according to the seriousness of the injury. The most important single factor and the common denominator in the treatment of all these injuries is the active, vigorous exercise of the quadriceps muscle. If this muscle is kept strong, a grave ligamentous instability may be entirely asymptomatic.

History of Medicine In Minnesota

MEDICINE AND ITS PRACTITIONERS IN OLMSTED COUNTY PRIOR TO 1900

NORA H. GUTHREY
Rochester, Minnesota

(Continued from the November Issue)

M. Holterman, of Rock Dell, Olmsted County, was listed as a physician in the 1878-1879 edition of the *Minnesota State Gazetteer and Business Directory.* Other information has not been available. It is possible, but not proved, that this practitioner was the Dr. N. S. Holterman, a Norwegian physician, who between 1874 and 1878 was in Kasson, Dodge County.

Joel H. Horton, an eclectic physician, practiced medicine in Rochester, Olmsted County, eight years or more beginning in 1881.

Born in Portage County, Ohio, on April 29, 1830, Joel H. Horton received his early education at Hiram Academy, Hiram, Ohio, and in 1852 took his degree of doctor of medicine at the Eclectic Medical College of Rochester, New York. In the next thirty years he practiced in various places, first in Wooster, Ohio, later in Michigan, in Iowa City, Iowa, and in Hiram, Ohio. From Ohio he came to Rochester, Minnesota, in the summer of 1881 and shortly afterward entered partnership with Dr. E. T. Sedgwick, also an eclectic, with offices in the Olds and Fishback Block on Broadway; Dr. Sedgwick had come to Rochester late in 1879 from Zumbrota. When this association ended, after three months, Dr. Horton took an office in the Heaney Block. In November, 1882, local newspapers stated that his daughter, Frances D. Horton, had come from Springfield, Ohio, to keep house for him at his residence on College Hill; and, a year or two later that Miss Horton had been married in Ohio to Harry Corey, of Fremont, that state.

Dr. Horton was an active member of the Minnesota State Eclectic Medical Society, attending meetings and presenting papers, notably one on eclecticism in medicine, at the fifteenth annual session of the society in June, 1883, at Owatonna; at that meeting he was elected a member of the board of censors. Under the medical practice act of 1883 he received Minnesota state license No. 693 (E), dated December 31, 1883, which he filed in Olmsted County on January 12, 1884.

This practitioner's name appeared occasionally in Rochester newspapers and in certain county records into 1890 and in successive issues of a state gazetteer and business directory from 1884 through 1891. It was not included in the first issue (1906) of the official directory of the American Medical Association nor thereafter.

Dr. Hunt was early in Pleasant Grove, Olmsted County. On March 6, 1869, the *Federal Union* of Rochester, in commenting on the prosperous village of Pleasant Grove, in the township of that name, and its fine class of people, said in part, "For instance, where will you find a more accomplished gentleman than Capt. Mills, Dr. Bardwell and the venerable and the good Dr. Hunt?" Dr. Hunt's name appeared in Mervin's *Business Directory* of 1869-1870, in relation to

Pleasant Grove, and an early settler of Rochester who is now very old has expressed the belief that Dr. Hunt at some time lived in Stewartville, seven miles from Pleasant Grove.

A. T. Hyde, "doctor" perhaps by courtesy, one in a large category throughout the country, was in Rochester, Minnesota, a few years in the late eighteen sixties. Sometimes described as botanist and chemist, he had his headquarters in the grocery store of S. H. Daniels, with whom he was for a time in partnership in the manufacture of Hyde's Gopher State Bitters. The *Rochester Post* of August 15, 1868, quoted the following comment from the *Chicago Republican:* "Rochester is meeting Pittsburgh half way and a bitter contest is on between the bitters produced in the two places. Hostetter has had the field in Chicago but Hyde's Gopher State Bitters are supplanting them. The inventor of these bitters, an experienced botanist, claims to have effected a combination of roots and herbs from western prairies that contain medicinal properties. It has recently been patented and is now manufactured by the laboratory of Daniels and Co. at Rochester. It is meeting with large sale in Minnesota and is gradually working its way into adjacent states. The bitters are highly recommended by those who have tried them." A few months later a grateful patient presented an especially engraved medal to Dr. Hyde as a token of his appreciation of the medical worth of the celebrated bitters; not long after that Dr. Hyde won a silver medal in a bitters competition. In November, 1869, it was announced that S. H. Daniels had purchased the interest of Dr. A. T. Hyde in the late firm of Daniels and Co. and would continue the drug and grocery business.

W. A. Hyde was in Rochester, Olmsted County, probably about three years. Through the summer and autumn of 1863 he announced himself in the local newspapers as physician and surgeon, residence with W. H. Mitchell, opposite the Stevens House, and office over the Union Drug Store (O. W. Anderson and A. F. Childs, proprietors), on Third Street. He asked a fair share of patronage, "having had ten years experience in the practice of his profession, and spent the last year as surgeon in the United States Service, in the *Land of Dixie."* In December, 1863 Dr. Hyde was appointed by the city council to take care of a smallpox patient, who was isolated in a disused log house on the edge of the city. Later it appeared that Dr. Hyde protested that the house was cold and unsuitable and he consequently was absolved of criticism when the patient died and was said to have frozen to death. For many weeks an acrimonious exchange, mentioned in the foregoing narrative, was carried on between newspapers, editors in near-by counties stressing various unpleasant points. Ultimately it became clear that the controversy arose primarily from political differences among editors.

In January, 1864, Dr. Hyde joined Dr. W. W. Mayo in a partnership that lasted less than four months. In June of that year Dr. Hyde was describing himself as an eclectic physician and surgeon, with office and residence upstairs on Broadway, opposite Dr. Cross. In the same month he was appointed city physician, to serve under the council until May 1, 1865.

In September, 1865, stating that he was about to cease the practice of medicine, Dr. Hyde gave "fair notice" and desired all those indebted to him for professional services to call and settle their accounts without delay, and shortly afterward he offered his house and lots for sale. His card continued to appear, nevertheless, and presently he was announced as practicing medicine in Eyota, where he remained some months. By December, 1865, he again was in Rochester and, indiscriminate as to school, was stating that he was a homeopathic physician and surgeon, office and residence on Broadway the first door north of Woodard and Ells Drugstore, his charges "no more than others practicing in this place. Old family medicine cases refilled or altered." In the same issue of the newspaper that carried this card appeared a paragraph, apparently from his hand, extolling the merits of homeopathy.

After July, 1866, although this practitioner may still have been in Rochester, notes about him did not appear in the press. Considerable detail regarding him has been given here because he seems to have been one of a numerous class, peculiar to the time, in claims of experience and abilities, and in changes of location and professed methods of practice.

The *Rochester Post* of July 7, 1893, in an item presumably authorized, stated that **Dr. Jackman,** of Jacksonville, Illinois, had accepted a position on the corps of assistant physicians at the Rochester State Hospital and that Dr. Jackman and Dr. Cyrus B. Eby, another new appointee, would complete the staff of assistant doctors. In none of the detailed published reports of the hospital nor in M. K. Amdur's "A Psychiatric Bulletin in Minnesota of Half a Century Ago" *(Minnesota Medicine,* September, 1942), in all of which are mentioned the physicians who would have been Dr. Jackman's immediate associates, does the name of Dr. Jackman appear.

Frank M. Johnson was in southern Minnesota as a general practitioner of medicine and surgery from 1883 into 1896 and in Olmsted County the last six years of that period.

Born at Fort Atkinson, Jefferson County, Wisconsin, on August 29, 1854, Frank M. Johnson when a child removed with his parents to Vernon County, that state, and there grew up. He attended the high school at Viroqua, took an academic course at Wayland Academy in 1876, and in the three years immediately following studied medicine with Dr. William Gott of Viroqua. Soon afterward he matriculated at Rush Medical College, from which he was graduated in 1882. The scene of his first practice, for a year and a half, was Ontario, Vernon County, Wisconsin, and there he was married to Ida De Lapp, a native of Ontario, born on December 2, 1860.

In September, 1883, Dr. and Mrs. Johnson and their infant son, Lee F. Johnson, removed to Brownsdale, Mower County, Minnesota. Dr. Johnson was licensed in Minnesota on December 31, 1883, receiving certificate No. 958 (R). From Brownsdale he transferred after two or three years to Grand Meadow, where he practiced and ran a drug store until January, 1890, when he settled in Byron, Olmsted County; Dr. Carlos R. Keyes had left Byron a few weeks earlier for Stillwater, where he was an assistant physician at the state prison.

The record in Byron is brief. Dr. Johnson and his family occupied the E. M. Gilbert residence after a few weeks at the Commercial House. A third child, a son, was born while they were in Byron, in December, 1890. Newspaper notes indicate that Mrs. Johnson had relatives in Plainview whom she visited; that the doctor was a Baptist and a prohibitionist, and that in June, 1890, he was nominated for coroner by the prohibition group.

Early in 1892 Dr. Johnson sold his practice to Dr. Amos L. Baker, who was coming to Byron from Pleasant Grove, and in April removed to Dover, where opportunity existed. Dr. A. W. Stinchfield, of Eyota, had joined the Drs. Mayo in Rochester, and Dr. Rollo C. Dugan, of Dover, had succeeded him in Eyota. Before entering the new field and occupying the former quarters of Dr. Hiram

C. Bear who had left Dover two years previously, Dr. Johnson took a postgraduate medical course in Chicago. He early became a member of the Southern Minnesota Medical Association, which was founded in July, 1892. Occasional local items concerning him have been noted: that he brought a patient to Rochester for the opinion of the Mayos; that he assisted Dr. William A. Chamberlain, of St. Charles, in surgical operations on various occasions; that Dr. Horace H. Witherstine of Rochester, went to Dover to see a patient with Dr. Johnson; that the latter had been called to Stewartville.

In May, 1896, the Dover correspondent of the *Rochester Post* stated that Dr. F. M. Johnson and his family had departed for Springfield, Missouri, where they intended to make their home. That residence has been confirmed by the official directory of the American Medical Association, in successive issues of which from 1906 to 1931, inclusive, Dr. Johnson was listed as of Springfield.

C. H. Johnston might be classed as an itinerant practitioner, at least in the years when he first came to Rochester, Minnesota. In November, 1878, he ran notices in the local newspapers that he would be available for consultation at the Pierce House on certain days in November and December. There is evidence, however that later he had his home in Rochester. In February, 1880, the *Rochester Post,* mentioning Dr. Johnston as formerly of this city, reported the birth of a daughter to Dr. and Mrs. Johnston, who then were living near Dodger Center. And in May, 1880, the same paper stated that Dr. Johnston, "a formerly well-known practitioner in this city," had built up a large practice in Minneapolis and Wisconsin and had chosen Minneapolis as a convenient location from which to meet the numerous calls made upon him from all points.

Lewis Halsey Kelley (1808-1872) was from 1857 to 1863 a respected physician and surgeon in Rochester, Olmsted County, and from 1860 to the end of his life a representative newspaper owner, editor and publisher, first in Rochester and subsequently in Owatonna, Northfield and Faribault. After leaving Rochester he practiced medicine to only a limited extent.

Born in Ovid, Seneca County, New York, on October 13, 1808, Lewis H. Kelley received his academic and medical education in schools and colleges in the East, and was married, about 1840, to Angeline E. Rich, of Richford, New York. Data are not exact but it is known that for some time he practiced medicine at Marathon, New York, and that in the middle eighteen forties the family removed to Painesville, Lake County, Ohio; there in 1847 a son, one of the family of eight children, was born. In the early summer of 1857 Dr. Kelley came with his wife and children to Rochester from Painesville in the hope that the Minnesota climate would benefit Mrs. Kelley, who was in failing health; she died in Rochester a few years later.

On arrival in Rochester Dr. Kelley began the practice of his profession. A year later, when the settlement had been incorporated as a city, he began the construction of his Brick Block, the first brick building in Rochester, at the northeast corner of Broadway and College Streets (the latter now Fourth Street, S. W.). Broadway in that day extended two blocks north of the building site, to lose itself in a hazel thicket. Brick for the block was burned in Whitcomb's kiln in East Rochester and was hauled by ox teams across the Zumbro River ford a stone's throw away from the chosen corner. This building of two stories, 22 x 70 feet, stood out in the irregular cluster of small buildings, of logs or boards, that predated it and formed the nucleus of the city. It gave stimulus to civic pride and ambition in Rochester and was for some time the center of activities in the settlement. The Kelley living quarters were on the ground floor rear of the new building; the lower front space was rented to various local merchants in turn: William McCullough, and F. W. Andrews, and Upman and Poole, druggists. The upper space was rented to Messrs. David and Cyrene Blakely, who in 1859 founded Rochester's first newspaper, the *Rochester City Post.* To this home Dr. Kelley brought the first piano ever owned in Rochester, an instrument fascinating to the entire community and most of all to the Indians who thronged the valley and the settlement. When the eldest Kelley daughter (later Mrs. Walter Crocker) played on the "music box," the red men crowded at the windows to watch and listen, grunting their amazement and approval.

Dr. Kelley's professional and training experience are best stated by himself: When in December, 1860, he returned to Rochester after a long absence, he published in the *Rochester Republican* (which he had established that year) his professional card and the following notice:

> Ho! Ye Afflicted! The undersigned would respectfully announce that on return from southern parts after nearly a year, he has made up his mind to locate permanently in the city of Rochester as a
>
> PHYSICIAN AND SURGEON.
>
> He would further state, for the information of the afflicted, that he received the degree of M. B. from the City of Albany, New York, while attending the Medical College of Geneva, New York, and subsequently received the Addendum Degree of his profession at the State Medical College of Indiana; is also a member of the New York State Medical Society and of the College of Physicians and Surgeons, Geneva, New York. And from his extensive practice in the healing art in the East, South, and West, for nearly twenty years, he has made himself acquainted with all the variations and grades of diseases, and feels that all confidences imposed on him in his profession will not be misplaced. He can be found at his office on the corner of Broadway and College Streets, between the hours of 9 a.m. and 3 p.m., on each day, for medical counsel.

An additional note from authentic source indicates that he was graduated from the Geneva Medical College in 1838 and from the Albany Medical College in 1840.

Dr. Kelley was a patriotic and public-spirited citizen who during the Civil War was "an unqualified terror to Copperheads of either side," and a generous helper to the loyal. His notice in his own paper and in other Rochester publications in August, 1862, expressed his wish to serve:

> Medical Notice. The undersigned, desirous of doing something for those who have left their wives and children at home in this city or county, and have volunteered or may volunteer in the service of the Army of the United States, for the purpose of defending the flag of our union and the liberties of our citizens from the ruthless hands of tyrants and traitors; to all such wives and children residing in this city, to them or any of them requiring medical attendance while their husbands and fathers are in actual service in the war now existing in this union, I hereby pledge to all such needful medical services when called upon, free of charge,—and to such persons residing in the county for one half of the usual fee for such services. Dated at the city of Rochester, Minnesota, August 12, 1862.

This physician had various special interests and affiliations. He and his wife were members and supporters of the local Methodist Church which was organized in 1856. Dr. Kelley in August, 1857, was an organizer and the first Worshipful Master of Rochester Lodge No. 21 (A. F. and A. M.). In 1860 "Senator" Kelley was a leader in a movement to improve the public schools of Rochester. In 1861 he was a founder, and the first president, of the Olmsted County Temperance Society.

As noted, Dr. Kelley early became a newspaper editor and publisher. In 1860 he bought (in partnership with his son-in-law W. H. Mitchell, who in 1866 published the first history of Olmsted County), the *Rochester City News* and converted it into the *Rochester Republican,* of which he became local editor in 1861. In the autumn of 1863 he sold the *Republican* and removed his printing equipment to Owatonna, Steele County, where he established the *Plain Dealer,* the first newspaper in that city. In 1868 he removed to Northfield, Rice County, and took over the *Northfield Recorder,* a little later the *Northfield Enterprise;* in 1870 he was in Faribault, publisher of the *Faribault Leader.*

In the summer of 1872, again living in Owatonna, Dr. Kelley lay seriously ill, having been in poor health for nearly a year, "with some disease that seems to baffle the skill of physicians; the doctor from a strong robust man weighing nearly 300 pounds, has gradually pined away . . ." Lewis Halsey Kelley died in Owatonna on September 9, 1872, aged sixty-four years. His funeral rites were conducted at Rochester with full Masonic ceremonies, and he was buried in Oakwood Cemetery beside his wife.

Of Dr. Kelley's family, one son James A. Kelley, died of tuberculosis in 1864 at the age of twenty-three years, at Bowling Green, Kentucky, where he had gone in hope of recovery. Lewis H. Kelley and Pembroke S. Kelley became well known in printing and newspaper circles of the state; in the early eighties they published the *Rochester Post* in the absence of the owner, the Hon. J. A. Leonard. Lewis died in 1892 at Wilmot, South Dakota, where he was publishing a newspaper; Pembroke died in 1929 in Rochester, where he long had had a job printing office. A note on the family appeared in the summer of 1906: the Kelley Brick Block, having become unsafe, was undergoing reconstruction, and the *Olmsted County Democrat,* in giving the history of the building, paid tribute to Dr. Kelley. There were in that year four of the family living: Pembroke; Mrs. Helen Kelley Hart, of California; Mrs. H. M. Lovell, of Minneapolis; and Mary Georgiana, wife of William H. Knapp, of Rochester. W. H. Knapp was for many years a prominent citizen of the city, merchant, business manager of the Rochester State Hospital, and finally executive officer of the Rochester Milling Company. In 1946 descendents of Dr. Lewis H. Kelley, resident in Rochester, were two grandsons, Harold W. Knapp and Spencer M. Knapp (died, 1947), and several great-grandchildren.

Patrick Nicholas Kelly (1858-1903), a native of Olmsted County, Minnesota, was from 1883 into 1890 a physician and surgeon, but chiefly physician and obstetrician, in Rochester.

Born in 1858 at a farm home in High Forest Township, in the vicinity of Carrollville, Patrick Nicholas Kelly was the son of James Kelly and Mary Rooney Kelly. Both parents were natives of Ireland, James Kelly of County Roscommon and Mary Rooney of County Leitrim; both came to America in the early fifties and west to Iowa, where they met and were married, in 1856, at Dubuque. Shortly after their marriage they settled in High Forest Township among neighbors of their own nationality and religious faith; they were among the organizers, in 1859, of St. Bridget's Roman Catholic Church. Their homestead lay about a mile and a half west of the church site. When their five children, Ellen, Mary, Alice, Bridget and Patrick Nicholas, were approaching their teens, Mr. and Mrs. Kelly rented the farm for a few years and removed to Austin to place them in school; later the family returned to the farm, and eventually made their home in Rochester.

Patrick Kelly early went to school in the home district and in Austin. His academic education he received at St. John's College, Collegeville, Minnesota, and at St. Francis Seminary, Milwaukee; his medical training at McGill University, Montreal, from which he took his degree of doctor of medicine in 1883 (sometimes erroneously stated as 1884). He received his Minnesota state license No. 298 (R) on November 10, 1883. Unlike many of his contemporaries, he did not study with a preceptor preliminary to taking his medical course, but during at least his first summer vacation from McGill he read medicine with Dr. Francis A. Sanborn, of Rochester, in offices at the back of the Hargesheimer Drug store on the corner of Broadway and Zumbro Streets, offices that served many different Rochester physicians, preceding and following Dr. Sanborn's occupancy.

On his return to Rochester after some months of postgraduate work in Montreal, Patrick N. Kelly, M.D., C.M., opened an office over Poole's Drug Store and there in April, 1884, he was joined in partnership by his classmate Dr. Robert B. Struthers (M.D., C.M., 1883). Dr. Struthers had come on a visit but within two weeks he took out his state license, No. 871 (R); he remained with Dr. Kelly several months before returning east. After a few years Dr. Kelly occupied larger offices in the Cook Hotel Block.

Six feet tall, slender, blue-eyed, well groomed, dignified by mustache and small side whiskers, the young physician in his twenty-fifth year began his career under good auspices. He came of a family well known and highly respected, possessed excellent native ability, was a brilliant student and had received the best of scientific training. Recollections of persons who knew him and the comments of the local press indicate that early in his professional life his health, probably never robust, began to be affected by the strenuous conditions of practice of time and place. There is more than one account of his country trips, his hazardous crossing of the Zumbro River in flood, of his losing his horse and almost his life in an icy freshet of Willow Brook south of town. Serious illness, accompanied by pulmonary hemorrhage, occurred in 1884, again in 1885, and in subsequent years, in which he was attended by his colleagues the Drs. Mayo and other physicians in the city. He nevertheless continued in active practice; was elected coroner of Olmsted County in 1886, and was for several years a member of the United States board of pension examiners. He was a member of the Catholic Order of Foresters. He was a constant student of biography, history and medicine; his large library was distinguished by many first editions, chiefly Bibles and medical works, in English, French, German and Norwegian.

In the summer of 1890, again having suffered from pulmonary hemorrhage, Dr. Kelly went abroad, to recuperate his health and to improve his knowledge, and studied for three months in London, Berlin and Paris. On his return to Minnesota he announced his removal to Wabasha, Wabasha County, where he occupied the offices previously used by Dr. W. H. Lincoln.

Dr. Kelly was a member of the Minnesota State Medical Society from 1884, a charter member of the Olmsted County Medical Society when it was revived in December, 1885, and a member of the Wabasha County Medical Society (its secretary, 1892-1894, and its vice president, 1900). His contribution of scientific papers to all these groups has been noted, particularly an article on diphtheria, which Dr. W. J. Mayo cited before the state society in 1886, and one on puerperal eclampsia. In Wabasha County, as in Olmsted County, it is said, he was coroner and member of the United States pension board.

Patrick N. Kelly was married in Wabasha on April 21, 1896, to Clara Ginther of that place. The only child of the marriage, a son, died on June 9, 1901. Mrs. Kelly's death occurred on March 9, 1902. At that time Dr. Kelly had been several years in ill health, obliged to spend periods of rest in the south and elsewhere. After his wife's death he returned to Olmsted County and in the summer and autumn of 1902 he lived near Simpson, practicing medicine when able. In December, 1902, he was taken to the farm home of his sister Bridget, wife of M. A. Keane, in Olmsted County, near Pine Island, Goodhue County.

Patrick Nicholas Kelly died at the Keane home on March 11, 1903, at the age of forty-five years, "a man of strictest integrity; as a son, a brother, husband, father, citizen and friend, he fulfilled his duty most faithfully." There were many breaks in the family circle within a few years. James Kelly, the father, died at the home of Mr. and Mrs. Keane in May, 1903. Bridget Kelly Keane died a few weeks later on July 23. Mary Rooney Kelly survived her husband until January, 1907, when she died at her home in Rochester. Bridget and Alice Kelly had been successful teachers in St. Paul; Alice gave up her work to take care of her mother. Ellen, the eldest daughter, had died in girlhood from tuberculosis; Mary became Sister Mary Irene, of the Franciscan Order, in Rochester.

In 1946 there were living of Dr. Kelly's relatives, one sister, Alice Kelly (Mrs. William H.) McGraw, a widow of Grand Forks, North Dakota; a nephew, John C. Keane a chemist, since 1944 general superintendent of the Utah-Idaho Sugar Company, of Salt Lake City, and three grand-nephews, sons of Mr. Keane and Isabelle Langer Keane, M.D.; Mrs. Keane before her marriage was a pediatrician in Minneapolis. A niece, Helen Keane, wife of J. C. Schilleter, who was connected with the Iowa State College, at Ames, died in 1931.

Burney J. Kendall (1848?-1926), physician and surgeon, who practiced in Olmsted County in the period of 1868-1870, was a native of Enosburg Falls, Franklin County, Vermont. Knowledge of him has been derived chiefly, from the reminiscences of the late Dr. David S. Fairchild of Clinton, Iowa, who in 1869-1872 conducted his initial practice of medicine in the village of High Forest, Olmsted County; Dr. Fairchild came to Minnesota from Vermont on the advice of Dr. Kendall, a friend of his youth in a neighboring village.

Dr. Kendall studied medicine under a preceptor in Vermont (it is not known whether he was a graduate of a medical school) and soon afterward came to Minnesota and settled in Marion, with his office in the home of Henry H. Beach of that village. During his stay in the county, Dr. Kendall was a member of the Olmsted County Medical Society and a physician to the Olmsted County poor farm.

After about two years, Dr. Fairchild recalled, Dr. Kendall, convinced that routine practice of regular medicine would not lead to fortune, returned to Vermont, where he began to experiment in concocting patent medicines: "In the course of time he fell on a combination of drugs which was thought to have a beneficial effect on spavin in horses, and by skillful advertising gained a considerable reputation among farmers and horsemen. For many years 'Kendall's Spavin Cure' had a wide reputation. The pictures of fine horses and handsome women ornamented the walls of drug stores everywhere, and fine teams of horses and wagons could be seen on all important highways and 'Kendall's Spavin Cure' was a household name far and wide." Dr. Kendall was not skilled in high finance, however, and was forced by a combine to sell out his interest for some $200,000. This considerable fortune, for that day, he invested in drug interests in Saratoga, New York, and in real estate in Omaha during boom time, with ultimate financial disaster. Dr. Fairchild said, "I saw Kendall but once after he left Marion in 1870. In 1926 I saw a notice of his death in an obscure Minnesota town."

Staunton B. Kendall (1808-1897), a homeopathic physician who for forty years was well known over a large portion of southern Minnesota, in 1883 was described as the pioneer physician of the region of Byron, Olmsted County.

Born on March 17, 1808, at Ira, Rutland County, Vermont he was the son of Ephraim Kendall and Lucinda Brown Kendall, who a few years earlier had come from England to the United States. Ephraim Kendall served with the American troops in the War of 1812.

When Staunton Kendall was thirteen years old he accompanied his parents to Canton, Bradford County, Pennsylvania, and there and at Wellsborough, in adjacent Tioga County, received his early education. On coming of age he learned carriage making, a trade which he followed until ill health forced him to abandon it. At the age of thirty-two years, he took up the study of medicine and after two years under Dr. Welles, a homeopathic physician, he began independent practice.

Staunton B. Kendall was married on December 18, 1832, to Fanny Fellows, a native of Shelburne, Franklin County, Massachusetts, born on March 15, 1815. In 1853 Dr. and Mrs. Kendall came west with their children. In Wyanet, Bureau County, Illinois, the doctor practiced medicine for three years. In 1856 he came to Dodge County, Minnesota, and took up land in Ashland Township. Six years later he sold the farm and bought land near Byron, Kalmar Township, Olmsted County, and after three years established the family home in Byron. In 1867 Dr. Kendall built Byron's first hotel, which he ran for eight years, after which his son, Joseph B. Kendall, took it over. In 1869 Dr. Kendall opened a drug department in his son's general store and there dispensed his own drugs. Eckman and Bigelow, in writing of early medicine in Dodge County, mentioned Dr. Kendall and quoted his granddaughter, Miss Aurilla Kendall, of Byron: "The older settlers say that they could get prescriptions filled in Byron when they couldn't get them in Rochester."

At all times Dr. Kendall practiced his profession in addition to following other occupations. He became well known to settlers living within a radius of fifty miles of Byron, and it was said that at the height of his work as a physician, in a year in which 700 patients came under his care, he lost only two, one from diphtheria and one from cerebral meningitis. Exceedingly active, abstemious, a Methodist, a Whig in early times and later a Republican, he was always honored and respected.

When the Southern Minnesota Homeopathic Medical Society was organized at Owatonna in October, 1871, Dr. Kendall was present with other homeopathic physicians from Olmsted County, and the following year he became a member. This society was an active component of the state homeopathic society. On May 28, 1883, Dr. Kendall received state exemption certificate No. 428-3 (H), on the basis of proved years of practice.

In the eighteen eighties Dr. Kendall gave up his long ride, as the expression was those days, but continued to practice in the village and to maintain his interest in local affairs. His wife died on March 25, 1885, at the age of seventy-two years. When Dr. Kendall died on November 9, 1897, in his ninetieth year, he was survived by four of the large family of children: two sons, Joseph B. Kendall of Byron, John Kendall, formerly of Dodge Center, then of Phoenix, Arizona; and two daughters, Mary Kendall (Mrs. George) Dearborn, of Hudson, Wisconsin, and Aurilla Kendall (Mrs. G. H.) Stevens, of St. Paul. In 1946 surviving Minnesota relatives of this pioneer physician were seven grandchildren: Miss Aurilla Kendall, of Byron; Mrs. M. F. Little, of Rochester; Miss Calla Kendall, of Minneapolis; all daughters of the Hon. Joseph B. Kendall, who, like his father, was long an influential figure in Olmsted County, in private business and in public affairs. Leonard Dearborn and George Dearborn were in St. Paul; Mrs. Helen Dearborn Huelster was in White Bear Lake; and Mrs. Ruth Dearborn was in San Francisco, California.

Carlos (sometimes given **Charles) Royal Keyes** (1856-1938) was from early 1882 into 1889 a resident physician and surgeon of Byron, Olmsted County, active in professional and civic affairs.

Born on April 21, 1856, at Chelsea, Orange County, Vermont, Charles R. Keyes was a son of Samuel M. Keyes and Olive Hanson Keyes, both of whom were natives of Chelsea, as were their parents. His maternal grandfather served on the American side in the War of 1812. Charles Keyes grew up on the home farm near Chelsea, attended the district school and Chelsea Academy, was a student at Dartmouth College, and on completion of two years at the medical department of the University of Vermont, at Burlington, he received the degree of doctor of medicine in 1881.

After practicing medicine a few months in Chelsea, Dr. Keyes came to Olmsted County, in February, 1882, and soon entered partnership with Dr. Isaac Hall Orcutt, of Byron. Dr. Orcutt was then relinquishing his professional ride and limiting himself to an office schedule. In January, 1883, Dr. Orcutt retired from practice, and as Dr. Staunton B. Kendall, venerable pioneer physician of Byron, was reducing his work, the young doctor was needed. Dr. Keyes was licensed in Minnesota on November 24, 1883, receiving certificate No. 383 (R).

In Byron, Dr. Keyes spent seven years that were filled with general village and country practice and active participation in community affairs. An old resident recalls him as short and slender, always kind, the finest of men. He was married on December 5, 1885, to Ella V. Sinclair, one of the six children of George Sinclair, farmer and native of Maine, who settled in Kalmar Township in 1856.

Dr. Keyes' professional card appeared in various newspapers of Dodge and Olmsted Counties. For a time he was local correspondent for the *Kasson Vindicator,* relaying news of Byron and Kalmar Township. He was a Baptist and a Republican; a member of the village council, its recorder and sometime president; president of the Byron Library Association, for which Mrs. Keyes was librarian. From 1882, succeeding Dr. Orcutt, through 1889, he was county physician for the village of Byron and the townships of Salem and Kalmar, and also was local health officer.

In December, 1889, Dr. Keyes accepted an appointment as assistant physician at the state prison at Stillwater, to begin on January 1, 1890. When he left Byron, the village announced its need of a physician, with the result that within a few weeks Dr. Frank M. Johnson came from Grand Meadow, Mower County.

Early in 1891 Dr. Keyes removed from Stillwater to West Duluth, where he spent the remainder of his long life, continuing in his tradition of professional and civic activity. He was a member of the Olmsted County Medical Society, the Minnesota State Medical Society, from 1888, the St. Louis County Medical Society and the American Medical Association. His favorite recreations in the Duluth era were hunting and curling.

After fifty-seven years as physician and surgeon Dr. Keyes died on August 10, 1938, at the Webber Hospital, Duluth, from coronary thrombosis, in his eighty-third year. Mrs. Keyes survived him.

(To be continued in the January issue)

President's Letter

THOUGHT AND CELEBRATION

With the holiday season—the religious significance of Christmas and the extended implication of new hope and new life that is inherent in New Year's celebrations—we come inevitably to a re-evaluation of fundamental values and objectives.

For, no matter how obscured with mythology and tinseled superficiality our observance of Christ's birthday becomes, still in some thoughtful and reflective moment we experience anew the inspiration that is centuries old and resolve to empower our lives with this moving force, rather than with the selfish personal ambitions that we often rationalize as independence and initiative.

It is a time for gratitude, humility and rededication to the principles of Christian living and, as physicians, we seek to apply those attitudes toward the conduct of our professional lives, so that our work may make its contribution to the advancement of humankind.

As physicians and as inhabitants of a world fraught with fear, frustration and suffering, we can be thankful, during this time of contemplation, for the miraculous discoveries of science that have been given us to use for the greater good of our fellow men. We can be grateful that freedom and human dignity, the God-given qualities that can make man godlike, have been preserved and regarded in a new light of reverence.

In wishing you the blessing of a joyous holiday, may I add, too, my appreciation for the opportunity of serving as your president this year and my thanks for the fellowship and co-operation you have unfailingly offered me.

J. J. Elias.

President, Minnesota State Medical Association

NPH INSULIN

THE IDEAL INSULIN would be one that had its maximum effect at the height of digestion of the three meals and minimum from midnight on.

The action of plain insulin is very fleeting. It was Hagedorn and his group in Denmark who discovered that the addition of protamine prolonged the action of insulin. The addition of zinc further prolongs the action. The addition of 1.25 mg. of protamine and 0.2 mg. of zinc per 100 units as in protamine zinc insulin prolongs the action of the insulin much longer than twenty-four hours and its initial action is so slight that frequently regular insulin must be added to provide early action after injection. The conversion of some of the regular insulin into protamine insulin by this mixing makes the amount of each in a mixture uncertain.

NPH insulin (neutral protamine Hagedorn) is an insulin with the addition of 0.5 mg. of protamine per 100 units and also zinc. Its action is said to last from twenty-six to thirty hours so that there is very little overlapping of dosage from day to day. Although it is not as prompt in its action as plain insulin, it is more prompt than protamine insulin, its maximum action coming seven to eleven hours after injection, and its action during the night being minimal. The new NPH insulin has been found to control the glycosuria in many diabetics who formerly required protamine and plain insulin mixtures. The elimination of the need for mixing two insulins is of course an advantage. It is claimed that plain insulin can be added to the NPH insulin without disturbing the prompt action of the plain because of the lesser content of protamine available for combination.

The NPH insulin is being widely used. It would seem that it represents a distinct advance in the insulin treatment of diabetes.

WORLD MEDICAL ASSOCIATION

SOME 500 medical leaders from twenty-eight nations of the world met in New York in October to discuss world medical and health problems. The World Medical Association is a voluntary organization of the national medical associations of forty-one countries. This is the fourth annual meeting and the first to meet in the United States.

Dr. Louis H. Bauer, chairman of the board of trustees of the AMA, is also secretary-general of the World Medical Association with headquarters in New York City.

Russia has never been represented in the WMA, and at present the countries in the Russian bloc also do not send representatives.

On October 17, Dr. Elmer L. Henderson of Louisville was inaugurated as president of the WMA. Last June he was inaugurated as president of the AMA and thus he holds the presidency of the two largest medical associations in the world. At his inauguration, he called attention to the fact that "physicians by their thinking, spirit and effort can set an example for governments, diplomats and people everywhere to preserve the peace."

Dr. Charles Hill of London, retiring president, was unable to attend, but in his message he expressed serious dissatisfaction with the present British National Health Service. He wrote that the general practitioner in England is losing both patients and prestige and that, if it becomes clear that no prospect for satisfactory settlement is in sight, "preparations should be made for a withdrawal of general practitioners from the National Health Service."

At one spirited session, delegates voted "to condemn the practice of euthanasia under all circumstances" as "contrary to the public interest and to medical principles as well as to natural and civil rights." Dr. S. G. Sen of India and Dr. E. A. Gregg of Great Britain favored "mercy death with the consent of the patient and the state to bring an end to intolerable suffering." Delegates from the United States, Ireland and

France were strongly opposed. Dr. Marcel Poumailloux of France declared that approval of euthanasia would "open the door to all possible crimes and criminal practices."

WMA delegates voted to authorize the council to consider any applications of doctors of Western Germany and Japan to membership, despite the protests of two Israeli physicians on the grounds that many doctors in Germany had been involved in such human experiments as forced sterilization and vivisection of humans.

Scientific sessions included addresses on the latest advances in endocrinology, gastroenterology and the therapeutic uses of blood and its derivatives.

Dr. Dag Knutson of Djursholm, Sweden, was unanimously chosen president-elect of the association to take office at the fifth general assembly of the WMA to be held in Stockholm, Sweden, September 15 to 20, 1951.

One courteous gesture in connection with this year's meeting was the defraying of the cost of meals for the foreign physicians during their five-day attendance by fourteen American business firms. Other prominent business concerns presented each of the 120 wives accompanying their physician husbands from all over the world with a gift package containing a variety of American products.

The World Medical Association surely offers a medium for promoting understanding throughout the world and has so far utilized its opportunities

POLIOMYELITIS IN MINNESOTA

THROUGH the courtesy of Dr. D. S. Fleming, chief of the Section of Preventable Diseases of the Minnesota Department of Health, we are able to report the incidence and mortality of poliomyelitis in Minnesota this year from January 1 to October 31.

The Minnesota Department of Health received reports of 418 cases of poliomyelitis, including seventeen deaths in Minnesota residents during this period. Sixty-two cases, including four deaths in out-of-state residents, were also reported.

It has long been recognized that poliomyelitis, while appearing sporadically in the winter months, has its greatest incidence in August, September and October. Poliomyelitis acted in this respect true to form again this year, as the following figures attest. The 418 cases had their onset as follows: January—9, February—1, March—2, April—1, May—4, June—11, July—34, August—120, September—140, October—96.

By sex, 239 (57 per cent) were male and 179 (43 per cent) were female. Of the seventeen deaths, ten patients were male.

According to age, 100 occurred in the first four years of life, 165 in the 5 to 14-year age group and 153 in the 15-year and older group. Three deaths occurred in the first age group (0 to 4 years); four in the second group (5 to 14 years); and ten in the third group (15 years and over).

By type, 206 were paralytic (75 bulbar and 131 spinal); 165 were non-paralytic, and 47 were not stated.

The 418 cases and seventeen deaths have been reported from fifty-eight counties, as follows:

County	*Cases*	*Deaths*
Aitkin	2	
Anoka	7	1
Becker	1	
Beltrami	0

Although the figures quoted are for the first ten months of 1950 only and a number of additional cases have already been reported since October 31, it is obvious that Minnesota has been fortunate this year in comparison with the ten worst years since 1915 as listed below:

Year	*Cases*	*Deaths*
1916	912	105
1921	702	102
1925	955	145
1930	479	37
1931	811	66
1939	564	53
1944	530	37
1946	2,881	226
1948	1,387	110
1949	1,715	110

MATERNAL MORTALITY STUDY IN MINNESOTA

The state-wide survey of maternal mortality being conducted by the Committee on Maternal Welfare of the Minnesota State Medical Association with the co-operation of the Minnesota Department of Health has been in progress since April 1, 1950. Up to this time, twenty maternal deaths have been reviewed. As a result of the study so far, it has become apparent to the Committee that several matters need to be emphasized and called to the attention of everyone concerned.

Physicians and personnel in charge of hospitals are urged again to report all maternal deaths promptly by telephone to the Division of Maternal and Child Health of the State Health Department at GLadstone 5973 (Minneapolis), reversing the charges for such calls. Early interviewing of physicians, nursing staff and immediate relatives concerned would be facilitated if this were done and would make for more accurate evaluation of mortality responsibility.

Physicians and hospitals are reminded that the study includes all female deaths where pregnancy is present, even though the pregnancy is not the cause of death. Furthermore, it includes all deaths occurring during a postpartum period of three months following delivery. To clarify the reporting of maternal deaths, therefore, the words "pregnancy" or "postpartum," whichever term applies, should be written on all death certificates to be included in this study, even though neither condition is the cause of death.

The need for adequate office and hospital records becomes increasingly apparent as the study progresses. Current notations on the case history of symptoms, findings, treatment, and progress of the case are extremely valuable in evaluating and placing the responsibility for a maternal death.

Physicians are reminded again that a copy of the Committee's findings in each maternal death may be obtained by the particular physician concerned upon his request.

The Committee is deeply appreciative of the excellent co-operation received thus far from all physicians and hospitals concerned in the present survey and believes that the findings of this study will be a potent influence in further reducing maternal mortality in Minnesota.

James J. Swendson, *Chairman,*
Committee on Maternal Welfare

CHRISTMAS SEALS

The tremendous cost of tuberculosis in terms of lives, suffering, and dollars is emphasized in the 1949-50 annual report of the National Tuberculosis Association.

Killing more than 40,000 persons a year, tuberculosis is responsible for more deaths in this country than all other infectious diseases combined and leads all diseases, infectious or not, as a cause of death in the age group from 15 to 34.

While the tragic cost of tuberculosis in broken lives and broken homes cannot be calculated, the report states that the monetary cost of tuberculosis is estimated at more than $350,000,000 a year. Included in this sum is the cost of care and service for the quarter of a million people known to have the disease and the search for an equal number believed to be tuberculosis victims but unknown to health departments. The sum does not include hospital construction costs.

Since the median age at which tuberculosis kills is 48, the report brings out that the disease each year is robbing the people of this country of 1,500,000 potential years of life, one million of which are working years. (These estimates are based on a life expectancy at birth of 65 and a working age limit of 65 years.)

Yet tuberculosis, a communicable disease, is also a preventable disease, the report states, and can be brought under complete control if the present campaign of the medical profession, the voluntary tuberculosis associations, and official health agencies is stepped up and relentlessly pursued.

Cited among the outstanding requirements to fight tuberculosis are a program geared to the needs of the day; further medical advances in the research and educational fields as well as in the diagnosis and treatment of the disease; more local health units to serve the health needs of all the people; a public better educated in the prevention and control of tuberculosis; more widespread efforts to find people with tuberculosis while the disease is still in an early stage; more hospital beds for tuberculosis patients; more nurses trained in the care of the tuberculous; improved services for tuberculosis patients, and international control of the disease.

While the prediction may be made that at some time in the future tuberculosis may become a medical rarity, the report stresses that close vigilance will always have to be maintained against it. It has already been the target, according to the report, of the "most widely organized, longest sustained, most productive campaign ever directed against a disease." The campaign was launched in 1904 with the organization of the National Tuberculosis Association, which today has 2,987 affiliated associations in the 48 states, the District of Columbia, Alaska, the Canal Zone, Hawaii, and Puerto Rico. The state Christmas Seal organization is the Minnesota Public Health Association.

Ninety-four per cent of the Christmas Seal funds raised is retained within the state where it was contributed to support state and local programs. Six per cent goes to the National Tuberculosis Association for medical research and other activities.

ADVISORY COMMITTEES TO SELECTIVE SERVICE

Instructions were sent out under date of November 17, 1950, to the members of the County Medical Advisory Committees to Selective Service. These committees in the the county medical societies are held responsible for carrying out the procedures set up by the National Advisory Committee to Selective Service. It is their duty to advise local Selective Service Boards within the county medical society area concerning classification of individual members of the local medical profession and, although the local Selective Service Boards are the final authority on deferments, they are expected to follow closely the recommendations of advisory committees.

The Presidential order says that registrants shall be deferred as hardship cases "only if it is determined that (their) induction into the armed forces would result in extreme hardship and privation to a wife, child, or parent with whom he maintains a bona fide family relationship in their home." The order says deferment because of essential service to community shall be granted only "when his induction would cause the availability of essential health services to fall below reasonable minimum standards" in his community.

In addition to the above, State and National Advisory Committee policy, at the present time, is to recommend deferment on the following basis:

(a) Physicians who have not completed at least one year of intern training.

(b) Senior residents prior to the completion of the current year's training.

(c) Full time postgraduate medical students until completion of the current academic year.

(d) Physicians in teaching or research whose activities are considered necessary to the national health, safety or interest.

As we have mentioned before:

First priorities are ASTP or V-12 students or others who were deferred during World War II to continue their education and who subsequently served less than ninety days.

Second priorities constitute those similarly deferred but who served more than ninety days and less than twenty-one months.

First priorities will be processed first.

State and local quotas will be based on the number of registrants in the various categories rather than on the total registration.

The Army is undertaking to offer a reserve commission to every registrant at the time he takes his physical examination and before his induction. However, physicians can volunteer for any military service up to the time they are inducted. Under the law, men involuntarily inducted may not receive the $100 monthly pay bonus which goes to volunteers.

MEDICAL ECONOMICS

Edited by the Committee on Medical Economics
of the
Minnesota State Medical Association
George Earl, M.D., Chairman

ELECTION OFFERS NEW CHALLENGE

Now that election noise has calmed down considerably, Americans can reflect upon and analyze the outcome.

Regardless of legislative implications, citizens should not sit back content and complacent, but should continue their vigilance of civic affairs. This public-spirited vigilance will maintain an America where all are free to elect or defeat candidates. Doctors, in their primary role as citizens, should continue their efforts to help keep America among the free nations of the world.

CANADIAN DOCTOR REPORTS ON BRITISH HEALTH SERVICE

Adding his voice to the many who are speaking out against the evils in the British national health service, Dr. A. W. H. Challis of Fort Frances, Canada, told Rotarians in International Falls, Minnesota, recently that "Britain's national health program has resulted in a record-breaking demand for medical and dental service at government expense." Dr. Challis, who reported on the British program from firsthand experience with it, stated that "about 80 per cent of the people who crowd doctors' waiting rooms probably don't need attention at all but must see a doctor to obtain permits for larger rations, discounts or special services."

Cites Overwork of M.D.'s

Dr. Challis stated that the role of "form-filler" isn't pleasing to Britain's doctors because they are trained "to do a special job and do it well." He said:

> "Of the remaining 20 per cent of Britishers who avail themselves of the public health service, about 10 per cent are really sick and the other 10 per cent have minor ailments and disorders that they would have treated themselves in the days before the practice of medicine was nationalized.
>
> "As a result of the heavy patronage, doctors of Britain are terrifically overworked and unable to render the high quality personalized service that the profession normally demands.
>
> "The average British doctor in the national health service will see as many as 100 patients during evening office hours. Much of his time is spent in filling out forms and permits for those not especially in need of attention, at a sacrifice for those who are seriously ill."

Paper Work Overwhelming

Citing the tremendous amount of paper work entailed in the daily operation of the British health system, Dr. Challis told Rotarians that a British doctor must carry as many as forty-two different kinds of government certificates in order to cope with any emergency he may be called upon to handle. "New demands for health service have crowded the hospitals to overflowing, just as they have burdened the individual practitioner. Hospital waiting lists are long and growing longer constantly," he said.

According to Dr. Challis, important surgical cases often have to wait from nine to twelve months. Lesser operations, such as tonsillectomies, have been known to be postponed eighteen to twenty-four months because hospital beds weren't available.

Warns of Mounting Costs

Dr. Challis cited a common fallacy about the cost of the program:

> ". . . the ordinary citizen considers the service cheap, if not free, but actually the program is very expensive. The high costs are reflected in very high taxes on incomes and almost everything else."

The quality of Britain's health service, Dr. Challis concluded, has suffered under the nationalized system. He said, "Britain would have benefited more by raising the general standard of health service under the private practice plan than by offering a lower grade of service on a wholesale scale to everybody, all at once."

LEGISLATOR ASSAILS FEDERAL LOBBYING

Representative Henry J. Latham of New York recently issued a charge that "certainly the federal lobby is the largest and most powerful with which congress must contend." His charge, that the government spends a billion dollars a year to lobby for its proposals, was a countercharge after the lobby investigation committee reported that 152 corporations spent over thirty million in the last three years to influence legislation.

Representative Latham, using studies showing that government lobbying far exceeded that of business, stated that the most conspicuous examples of federal lobbying are the "campaigns for the Brannan plan and compulsory medical insurance."

Latham attacked the trip to Europe of Federal Security Administrator Oscar Ewing and a party of assistants, as "an effort to spread propaganda for the proposed Truman medical program."

Government Printing Tremendous

Studies on government printing alone show that costs run to over $50,000,000 a year, according to Representative Latham. He referred to a study made by Representative E. H. Rees of Kansas, showing sixty-one separate government printing and duplicating plants in Washington, twenty-three in Philadelphia, and sixteen in Chicago, and their respective operating costs.

GOVERNMENT DEBT BIGGER THAN EVER

Almost simultaneously, the Commerce Department issued a statement saying that the "federal government entered this year deeper in debt than all the private firms and individuals put together." The total net federal debt was put at $218,600,000,000, with state and local governments owing another $18,000,000,000.

With the government spending more for lobbying than private interests spend, and involved in more debt than "private firms and individuals put together," some of those individuals might wonder how they would finance the more than $1,500 they would be slated for if the amount were divided evenly among American men, women and children.

HEALTH INSURANCE BOOK ISSUED BY COMMITTEE

The most extensive summary of the arguments for national compulsory health insurance yet assembled, is contained in the new book issued by the Committee for the Nation's Health entitled, "National Health Insurance Handbook—A Practical Guide for Leaders."

The handbook is picayunish, calls names and is based on a false premise. Arguments that compulsory health insurance is not socialized medicine are useless from the start, because any personal service, like medicine, that is administered in compulsory form from the government down to the individual, is, by nature, socialistic.

The book attempts to convince the reader that health insurance is desirable by saying, "NATIONAL HEALTH INSURANCE is a sound American plan of insurance—like Social Security." Obviously, Social Security is not like insurance: almost everyone pays for Social Security, yet there are countless restrictions, rules and regulations on who can and who cannot receive benefits.

In reporting on Americans who favor the plan, the book points proudly to men like Dr. Harold S. Diehl, dean of the University of Minnesota Medical School, twisting his words to put him in the position of favoring the British plan. The book claims Diehl as a national health insurance partisan, but does it through inaccurate and incomplete quotes. What his report really concluded was this:

> "The National Health Service Act is only one facet of British socialism; the welfare state does not exist except as a part of the whole. Furthermore, conditions in Great Britain are so different from those in the United States that it would be folly to contend that what may be necessary for Britain today should be admirable for transfer to the United States. We, fortunately, have the time that is necessary to evolve an adequate medical service for our people without resorting to the centralization of authority in a welfare state."

Misused Words

The book makes flagrant misuse of many words. Among them: "American critics of the British program talk about 'bureaucracy' but avoid actual facts and figures on administration costs." When "critics of the British program" speak of bureaucracy, they are speaking of inevitable costs. They ask "How can costs of bureaucracy be avoided?" and "How can full and complete estimates of cost be made before any administration of the plan is done?" Whenever a middleman is set up between the individual and the goods and services he needs, the costs of those goods and services are bound to rise.

The new booklet presents a "Fact vs. Fiction" section with the warning for the reader to "Remember—the loaded questions are theirs" (meaning the AMA's). One of the questions presented is this:

> "WILL PEOPLE WHO DO NOT WISH TO USE THE GOVERNMENT SERVICE HAVE TO PAY THE TAX?
>
> "Lobbyists say:
>
> "Yes. Everybody with a paycheck will pay the tax, whether he uses the service or not.'
>
> "The truth is:
>
> "Yes, just as we support our police and fire departments though we may not need help.
>
> "Similarly, we also support our public schools, whether we send children there or not."

But obviously, thinking Americans will know that compulsory medicine, with everyone forfeiting a tax out of his paycheck, is the real beginning of more and more compulsion in more and more fields. It is no more difficult, nor more disturbing to think of socialization of the dairy industry, the grocery industry, the lawyers, the steel industry or the clothing industry. Then, Americans would be taxed to get "free" handling of law cases, or "free" steel girders, needed or not.

In such a case, the greatest blow of all would be suffered by traditionally American individual initiative.

Comparing an individual service like medicine to a standardized service like public schools, fire and police departments, is illogical thinking. It opens the way for government control of other individual and personal phases of American life.

MICHIGAN DOCTOR HITS GOVERNMENT MEDICINE

To help combat the forces which make socialistic schemes like government medicine seem favorable to unsuspecting Americans, physicians like Dr. L. Fernald Foster, secretary of the Michigan State Medical Society, are giving the actual facts to the American people. Recently Dr. Foster based a radio talk on the idea that truth is stronger than falsehood, proceeding from there to express the ideas that many doctors would like to put to their patients as aptly. Refuting many of the falsehoods used against American medicine, he said:

> "Fortunately for scientific medicine and perhaps unfortunately for your future health, doctors of medicine are not propagandists. They do not know the art of the 'Big Lie,' which, I am told, if repeated often enough, becomes accepted as truth. They do not practice the art of spreading malicious rumor for they are trained, as you want them to be, in keeping inviolate your confidence and your trust. Doctors of medicine are not generally great writers or speakers. They could not from the rigorous demands of medical education conscientiously devote sufficient time to become masters of the spoken word and engage in malicious propaganda techniques. This the doctors of medicine do know: they know how to keep you healthy; they know how to care for you when you are sick; they recognize and are intensely aware of those factors, both economic and social, that can and do affect your health and well being."

Medicine "Fighting Mad"

Dr. Foster told listeners that because the above things are true, the medical profession is "fighting mad today and is assuming a militant attitude against the purveyors of malicious lies. The profession has no quarrel with Mr. Taxpayer. It is angered because your tax money is being used freely by the propagandists to spread brutal falsehoods which hurt you and your chances for continued good health."

Fake Doctor Committed to Minneapolis Workhouse for Ten Months

Re: State of Minnesota vs. Frank Herman Gold, also known as "Dr." Frank H. Gould.

On October 25, 1950, Judge John A. Weeks of the District Court of Hennepin County, made an order committing Frank Herman Gold, also known as "Dr." Frank H. Gould, thirty-three years of age, to the Minneapolis Workhouse to serve the balance of a one-year sentence imposed upon Gold by Judge Weeks on January 24, 1950. Gold had been released from the Minneapolis Workhouse on March 21, 1950, on his plea that he had been adequately punished and that he desired to rejoin his family in the State of Washington. Subsequent investigation disclosed that Gold was working in a drug store on University Avenue in Saint Paul. This was in violation of the Court's order releasing Gold.

The Minnesota State Board of Medical Examiners learned that Gold was also representing himself as "Dr." Gould and advising people that he was going into partnership with a physician and surgeon, notwithstanding the fact that he has no medical training of any kind. Through the assistance of Mr. James F. Lynch, County Attorney of Ramsey County, and Saint Paul Police officers, Gold was apprehended on October 23, 1950. At the time of his arrest, Gold attempted to dispose of a stethoscope and other medical articles. The matter was called to the attention of Judge Weeks, who promptly issued an order vacating the order made by the Court on March 21, 1950, and ordering Gold returned to the Minneapolis Workhouse to serve the balance of his sentence.

QUESTIONS ON DRAFT LAW

Certain physicians, holding a degree of Bachelor of Medicine or of Doctor of Medicine, are presently liable for actual induction into the Army as recruits if they do not hold reserve commissions as medical officers in one of the armed services, whether in practice or not.

Non-veteran physicians, under twenty-six, were eligible for the draft before passage of the recent amendment to the Selective Service Act.

As a result of this amendment, physicians who were deferred from service and who thus continued their educations during World War II, whether at government expense or their own expense, and who have not served since then on active duty as medical officers for a period of twenty-one months, are subject to active duty as medical officers for twenty-one months.

Whether or not these physicians will be inducted into the Army as recruits or whether they will be deferred from service is entirely up to their local draft boards. Selective Service does not recommend deferment until completion of twelve months of internship.

These physicians, in other words, must apply for commissions as reserve officers or run the risk of induction as recruits. A physician who receives his actual induction notice may not then apply for a reserve commission and must enter service just as any other inductee. This does not apply to the notice to report for a pre-induction physical examination. Once he has been inducted into the Army as an enlisted man he may apply for a commission, but he will not be eligible for the extra $100 a month that is paid to all other medical officers.

None of the three military departments orders its reserve medical officers to active duty until they have completed at least twelve months of internship. In addition, reserve officers in their senior year of residency training will not be called to active duty until they complete their training, if at all possible.

It is rarely possible for a physician to apply for a reserve commission in the service of his choice.

Physicians now eligible for the draft who do not pass their physicals for commissions as reserve officers will not be inducted into the Army at a later time.

It is now possible to apply for a reserve commission without applying for active duty at the same time.

It is also possible now to apply for a reserve commission at the headquarters of military or naval districts, Army areas or numbered Air Forces.

Whether ordered to active duty as a medical officer or inducted for service as an enlisted man, the period of service is the same—twenty-one months.—Excerpt from AMA *Secretary's Letter.*

Minnesota Academy of Medicine

Meeting of May 10, 1950

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club, Saint Paul, on May 10, 1950.

Dinner was served at 7:00 o'clock and the meeting was called to order at 8:00 p.m. by the President Dr. William A. Hanson.

There were fifty-two members and one guest present.

Dr. Hammes read the following memorial to Dr. J. C. McKinley.

J. C. McKINLEY

1891-1950

Dr. J. C. McKinley was born in Duluth, Minnesota, on November 8, 1891. He died on January 3, 1950, after an illness of four and one-half years.

He was the son of John and Alice (Frizzell) McKinley. He received his preliminary and high school education in Duluth, Minneapolis and New York City. He was graduated from the University of Minnesota in 1915 with a B.S. degree; in 1917 with an M.A. degree in anatomy; in 1919 with an M.D. degree; and in 1921 with a Ph.D. degree in nervous and mental diseases. His thesis was "The Intraneural Plexus of Fasciculi and Fibers in the Sciatic Nerve." He was a Diplomate of the American Board of Psychiatry and Neurology and a member of the Board of Directors of the American Board of Psychiatry and Neurology from 1941 to 1945. He was secretary-treasurer of the Minnesota State Board of Examiners in the Basic Sciences from 1931 to 1945. He held the following appointments during his academic career: 1915-1917, student assistant in anatomy; 1917-1918, instructor in pathology; 1918-1921, teaching fellow in neuropsychiatry; 1921-1925, associate professor of neuropathology; 1925-1929, associate professor of neurology—all at the University of Minnesota. In 1928-1929 he received a John Simon Guggenheim Fellowship and studied in Europe at Breslau and Munich. He returned from Europe in 1929, and from that time until 1945 he held the position of professor of neuropsychiatry at the University of Minnesota. In 1932 he became acting head of the entire Department of Medicine at the University of Minnesota, a position which he held through 1943. From 1943 to 1945 he was head of the Department of Neuropsychiatry and director of the Psychopathic Unit at the University of Minnesota Hospitals. From June, 1946, until the time of his death he was professor emeritus of psychiatry and neurology at the University of Minnesota.

Dr. McKinley, during his academic career, held many important positions. He was chairman of the Committee on Nervous and Mental Diseases in the Minnesota State Medical Association from 1943 to 1945. He was president of the Minnesota Pathological Society from 1946 to 1947, and president of the Central Neuropsychiatric Association in 1939. Dr. McKinley was a member of many societies, among which might be listed: Minnesota Society of Psychiatry and Neurology, Central Clinical Research Club, Central Neuropsychiatric Association, Fellow of the American Medical Association, Society of Experimental Biology and Medicine, Fellow of the American Association for the Advancement of Science, and American Neurological Association. He was elected to the Minnesota Academy of Medicine on October 8, 1930, and the title of his thesis was "Familial Diffuse Sclerosis of the Brain."

Dr. McKinley, during his career, published a large number of scientific articles. He was editor of the *Outlines of Neuropsychiatry* and co-author with Dr. S. R. Hathaway of the Minnesota Multiphasic Personality Inventory. He was listed in *Who's Who in America, Who's Who in American Men of Science, Who's Important in Medicine, Biographical Encyclopedia of the World, Who's Who in American Education,* and *Who's Who in Minnesota.*

He was married to Doris I. Swedien on April 29, 1944. He also had four children by a previous marriage. Mrs. Leland Phelps, Mrs. George W. Miners, Mrs. Fernando Machado, and John Charnley McKinley.

Dr. McKinley was an outstanding scientist and teacher in his chosen field. He was beloved by his students and the entire medical faculty. He exerted tremendous influence in developing the Department of Neurology and Psychiatry at the University of Minnesota to its high standing at the present time. His guiding influence, his scientific ability, and his kind and co-operative spirit to his fellow workers will be remembered by and be helpful to all of us who were closely associated with him.

E. M. Hammes, M.D.

The scientific program followed.

Dr. John M. Culligan, of Saint Paul, read his inaugural thesis.

THE PRESENT STATUS OF SURGERY OF THE SPLEEN

JOHN M. CULLIGAN, M.D., and JOHN A. CULLIGAN, M.B.
Saint Paul, Minnesota

The spleen is a mysterious organ of the body, possessing manifold functions. The complexity of its cell structure in an organ composed principally of lymphoid tissue confuses its physiology and makes a study of its functions extremely difficult. As the result of this complex nature, conclusions have had to be reached mainly by a process of trial and error. The multiplicity of different kinds of blood dyscrasias is only limited by the number of different blood cells. Whereas years ago many types of dyscrasias were lumped together under such diagnoses as splenic anemia or leukemia, we are now breaking these anemias down into more accurate terms depending on fine distinctions of the one type of blood cell involved. As more precise diagnoses are made, more exact indications for splenectomy will be achieved. Whereas splenectomy helped some of the old cases of splenic anemia, it failed in others completely. This no doubt was due to the fact that splenic anemia was a "catch-all" diagnosis. With the breakdown of this "catch-all" we learn which specific blood cell dyscrasias respond to splenectomy and which ones do not. Splenectomy has now been tried for every kind of anemia and splenomegaly and in sufficient numbers to arrive at some definite conclusions as to when it is indicated.

Among the conditions for which surgery of the spleen has been tried are the following: infections of the spleen from septicemia, pernicious anemia, myelogenous and lymphatic leukemia, Hodgkin's disease, aplastic anemia, polycythemia, luetic spleens, tuberculous spleens, splenomegaly due to malaria, splenic anemia, Banti's disease, sarcoidosis, trauma of the spleen, hemolytic icterus, congenital or acquired, thrombocytopenic purpura, splenic neutropenia, primary splenic panhematocytopenia, Felty's syndrome, thrombosis or anomalous obstruction of the portal vein with portal hypertension, cysts of the spleen, parasitic invasion of the spleen, abscesses, Gaucher's disease and ptosis. In many of the above-listed diseases, surgery of the spleen has been abandoned because of poor results or because some better treatmnet has been developed.

The physiology of the spleen is complex and must be studied from two angles, the normal and the abnormal. The spleen is primarily an organ composed of lymphoid and reticulo-endothelial cells and as such possesses all the normal functions peculiar to lymphoid tissue. Normally it acts as a reservoir for red blood cells, and helps destroy old red blood cells by phagocytosis and so forms bilirubin. It stores hemosiderin, phagocytes bacteria and foreign body particles. It produces lymphocytes and monocytes, and in embryonic life and in certain types of anemia in adults it produces red blood cells and leukocytes. When abnormal physiology in the spleen occurs, diseases result which arouse the interest of clinicians and which may necessitate surgical intervention. The function of increasing the fragility of the red blood cells is one. This increased fragility leads to the development of hemolytic icterus due to the rapid destruction of the red blood cells and the accumulation of bilirubin in the blood. The abnormal physiology of inhibitory function on the bone marrow reduces the platelets to the point that thrombocytopenic purpura results. If the inhibition of granulocytes occurs, panhematocytopenia or splenic neutropenia result. At times all of these conditions may be present simultaneously, or any combinations of the above. In spite of the manifold and complex functions of the spleen, it is remarkable that so little change results generally in the body from removal of a normally functioning organ. Aside from some increase in erythrocytes, leukocytes and blood platelets, there seems to be little or no effect on the body generally. This is no doubt due to the fact that there is still an abundance of lymphoid and reticulo-endothelial tissue elsewhere in the body. As these tissues assume the functions of the spleen, the increase in the blood components returns to normal. Removal, however, of an abnormally functioning spleen gives almost startling curative effects in cases carefully selected with certain characteristic changes in the blood or other organs. The close co-operation between the internist and the surgeon is most essential, and it is only by this means that splenic syndromes amenable to surgery can be sifted. A trained hematologist with ability to obtain accurate bone marrow studies is absolutely essential in arriving at the fine differential diagnoses necessary to obtain good surgical results.

The technique of splenectomy is not up for discussion in this paper, but we wish to make just one or two remarks relative to it. Either a left upper rectus or transverse incision may be used. Delivery of the spleen through this wound should be accomplished before the pedicle is clamped. This may be best accomplished by incising the parietal peritoneum just lateral to the spleen. A search for accessory spleens should always be made as they are very common. In cases where gross splenomegaly is present, preoperative shrinkage by x-ray therapy may facilitate its removal.

I have divided the cases under consideration in this paper into four groups.

1. Those in which splenectomy now offers nothing or is contraindicated due to the fact that failure has resulted from removal in the past or some other type of treatment has given better results.
2. Conditions in which splenectomy may palliate though it may not be regarded as a cure.
3. Conditions in which splenectomy is definitely indicated and give on the whole excellent results.
4. Rare conditions with which we have had no experience but are enumerated here so that they may be considered and evaluated as experimental to complete the record.

The first group includes the following conditions:

Infections of the spleen resulting from generalized septicemia or endocarditis have never responded to any surgical procedure. The sulfonamides and the antibiotics have replaced surgery.

Pernicious anemia was at one time thought to be influenced favorably by splenectomy but the discovery of liver therapy proved so much more efficacious that it naturally has superceded all operative measures.

Myelogenous and lymphatic leukemia never responded in any satisfactory manner to surgical intervention.

Hodgkin's disease responds better at least temporarily to Roentgen therapy and aplastic anemia has never given any gratifying results.

Polycythemia was once thought to be partially benefited but further study and observations has led to the conclusion that surgery on the spleen offers little or nothing. In fact in this condition it is now the consensus of opinion that surgery is contraindicated.

In the second group are cases which may receive some palliation from splenectomy. Certain types of infections of the spleen, such as luetic gumma, tuberculosis and even malaria, may produce such enlargement of the spleen that removal makes the patient much more comfortable though no change in the course of the disease may be obtained. Splenectomy therefore may be indicated when the spleen is so large or painful as to be annoying to the patient.

Lymphosarcoma may involve the spleen along with other abdominal or retroperitoneal organs. Removal of the spleen and as much as possible of the rest of the involved tissue may give palliation. This should be augmented with deep roentgen therapy.

A case in point is that of K. T., a twenty-three-year-old, single man seen in April, 1948, who first noted symptoms of pain in the left upper quadrant of his abdomen in the fall of 1944. This recurred in the spring of 1947 and a mass developed in the left upper quadrant of his abdomen. On April 10, 1948, splenectomy and removal of much other sarcomatous tissue was performed. His recovery was good, and following this, roentgen therapy shrank the mass considerably. He remained fairly well until December 5, 1948, when he died. Postmortem examination revealed death was due to a large intra-abdominal hemorrhage.

Sarcoidosis of the spleen is rare and is usually associated with evidence of sarcoid disease elsewhere in the body. This peculiar hobnailed spleen may give the patient extreme pain. The organ may increase in size until it weighs 1500 to 2000 grams. Whereas splenectomy may not effect the course of the disease, the relief of the pain is enough to warrant operation.

An illustrative case is M. C., a thirty-six-year-old, single woman who suffered extremely severe left upper quadrant pain associated with extreme spells of vomiting, lassitude, weakness and joint pains and a 33 pound weight loss in the preceding year. Examination revealed a large hard spleen. Exploration disclosed a hobnailed spleen which was removed. It weighed 2.5 pounds and the pathological report by Dr. John Noble was sarcoidosis of the spleen. She has been much improved since her operation, but once or twice a year still has attacks of colicky left upper quadrant pain. There is no evidence of progression of sarcoidosis elsewhere in the body.

Splenic anemia has been a catch-all diagnosis into which many obscure blood dyscrasias have been placed and some of which have been benefited by splenectomy. In more recent years certain rather distinct clinical syndromes such as panhematocytopenia and splenic neutropenia have been sifted out and will be considered later under group three. However, we think it is justifiable to advocate splenectomy for primary splenic anemia which does not fall into definite classifications because sometimes very startling cures result and no other treatment has been advanced which is better.

Banti's disease with its splenomegaly, fibrosis or cirrhosis of the liver and portal thrombosis presents pictures of such a varied nature that it is difficult to draw conclusions about the disease in its entirety. Treatment must be guided by the stage of the disease. We feel that we can conclude that in the early stages of Banti's disease before changes have taken place in the liver or the portal vein, splenectomy is beneficial. It certainly has a palliative effect and some observers believe that in real early stages it is curative. After the disease is well established, palliation is all that can be hoped for. In the late stages where collateral circulation is established, splenectomy carries a very high mortality from hemorrhage and shock but it may even be harmful because some of the collateral circulation may be destroyed. Because of these considerations splenectomy may be even contraindicated in this disease.

The case of R. K. was that of a twenty-year-old boy who had suffered from splenomegaly since the age of fourteen years. During these six years he suffered from two episodes of gastrointestinal hemorrhage probably arising from esophageal varices. The spleen had enlarged so that it extended low into the left lower quadrant of the abdomen. Splenectomy was performed in October, 1946, and a spleen weighing 1310 grams removed. The pathological report was Banti's disease. The patient received definite palliation from his symptoms but has had one spell of gastrointestinal hemorrhage since surgery. Otherwise he feels well three and one-half years after his operation. Perhaps if this spleen had been removed four or five years earlier we might have had a complete cure.

The third group contains those cases in which splenectomy is highly beneficial or curative:

Trauma of the spleen results usually from three causes: (1) injury caused by heavy dull or crushing blows to the abdomen, (2) perforating wounds, and (3) injury at a surgical procedure. The first type results most frequently from automobile accidents, sliding and bobsledding in which the injured strikes a firmly fixed object such as a tree, and occasionally in falls from any type of perch. The symptoms are generalized abdominal pain usually more marked on the left side, sometimes referred downward or to the left shoulder (Kehr's sign), pallor, occasionally vomiting, anxious appearance, sweating, thoracic breathing, splinting of the abdomen. Physical findings usually show evidence of shock, rapid thready pulse, clammy skin, abdominal rigidity, and rebound tenderness more marked on the left side. The skin seems to take on a yellowish tint, the blood pressure findings are usually low to normal, and at times there is fixed dullness in the left upper quadrant (Ballance's sign). This was present in two of our nineteen cases of ruptured spleen. But was probably not looked for routinely. With such a picture, immediate exploration is indicated. One complication of rupture of the spleen which must always be remembered is delayed hemorrhage. A history of abdominal trauma is obtained but the patient does not have the shock symptoms of one with a frank rupture and intra-abdominal hemorrhage. No indication for explorations is present. However, any time up to ten to fourteen days later, sudden shock symptoms appear and the typical picture of a ruptured spleen sets in. This is caused by a tear in the splenic pulp which is loosely sealed over and the capsule holds the hemorrhage in abeyance until it reruptures later as the clot in the spleen increases in size. This was present in two of our nineteen cases.

A case in point is B. T., a thirteen-year-old girl who was hit just below the left costal margin by the handlebar of a bicycle. She had some pain in the left flank with nausea at the time, but was able to attend school the next day and for the rest of the week. Pain was present in the left side only upon twisting her body or breathing deeply. During the night of the fifth day following the accident she was awakened by a severe pain in her left side, constant and worse upon breathing. She was brought to the hospital where she was found to have considerable tenderness in the left upper quadrant and left flank, with rigidity of the entire abdomen, most pronounced in the left upper quadrant. There was a moderate amount of distention. The hemoglobin was 48 per cent and shortly later 42 per cent. She was operated upon and a subcapsular hemorrhage and hematoma found with free bleeding into the peritoneal cavity. Recovery was uneventful.

Another case is that of S. L., a young man, aged twenty, who, while playing basketball ten days prior to admission, was hit in the left side of the abdomen by the head of another player. For the next five days he had considerable malaise, tenderness around his umbilicus, and pain upon respiration. On the sixth day he felt fairly well and went to work, but on the following two days had a recurrence of the pain which necessitated his staying in bed. Again on the ninth day he returned to work but while there developed profuse sweating, dizziness, and nausea and vomiting. He was brought to the hospital where examination of the abdomen showed diffuse tenderness with moderate rigidity. Blood pressure was 95/54. The hemoglobin was 68 per cent, red blood count 3,520,000, and the white blood count 13,200. At operation the spleen was ruptured and markedly enlarged. Pathological examination did not disclose the reason for the splenomegaly, but the pathologists suggested a blood dyscrasia or some such severe infection as bacterial endocarditis. Blood studies and cultures, stool cultures, and agglutination tests were all negative. After a very stormy course during which he developed bronchopneumonia with pleural effusion, subphrenic abscess, and evisceration of his wound, he died upon the thirty-sixth postoperative day. Autopsy showed areas of ulceration corresponding to the location of Peyer's patches, and the microscopic picture was compatible with a diagnosis of typhoid fever.

One of the difficulties in arriving at a diagnosis of rupture of the spleen is that frequently extensive injuries are present eleswhere which mask the symptoms. That is, the patient may be unconscious from concussion or skull fracture, he may be intoxicated, he may have a crushing injury to his chest with fractured ribs, pneumothorax or hematothorax, he may have fractured arms or legs, he may have rupture or perforation of other abdominal organs, or he may have rupture or perforation of the left kidney with hematuria. Any combination of the above listed injuries may be present and will have to be treated at the same time. However, as a general rule the other injuries may be more safely temporized with than the spleen injury because an untreated ruptured spleen is always fatal, whereas treatment of many of the other injuries may be delayed. Rupture of the spleen in extensive injuries should always be considered. It has often been referred to as the organ of shock in abdominal injuries, and where shock is present, rupture of the spleen and other abdominal organs should be considered. In our series of cases we had to remove the spleen and left kidney on four patients, two for simultaneous rupture of the spleen and left kidney due to the dull blows and twice for perforating bullet wounds which punctured both the spleen and kidney. This brings us to the second type of injury to the spleen, namely, perforating wound. These usually result from gunshot and stab wounds. The dictum of immediate exploration holds for this type of injury along with repairing any other type of injury which is present.

There was the case of T. O., a twenty-two-year-old man, with suicidal intent, placed the butt of a shotgun on the floor, leaned over the muzzle and reached down and pulled the trigger. The shot tore away the left upper quadrant of his abdomen and lower ribs and diaphragm. He was brought to the hospital gasping for breath because of a pneumothorax. The bowel was eviscerated. The patient was in shock. Supportive measures were instituted. Through the gaping wound the diaphragm was sutured to the lateral chest wall in a position higher than its normal attachment with through-and-through catgut sutures. Breathing immediately improved. The shredded ends of the tenth and eleventh ribs were removed. A splenectomy was performed. More than forty perforations of the large and small bowel were closed. The left kidney was not removed though shot could be felt in the capsule. A large retroperitoneal hemorrhage had occurred. The wound was closed as well as possible. For a time it seemed as though the patient might recover, but death occurred on the sixteenth postoperative day. The cause of death reported at postmortem was local peritonitis, subdiaphragmatic abscess, left empyema, abscess of left lung, multiple abscesses of left kidney. It is interesting to speculate on how the defect in the abdominal wall could have been repaired had the patient recovered.

Another case is that of H. I., a nineteen-year-old clerk in a drug store who was held up and shot in the abdomen by a bandit. The patient was in extreme shock. Supportive measures were instituted. The bullet had entered the abdomen in the left upper quadrant and lodged in the lumbar muscles. On exploration through a left rectus incision, it was found that the bullet had perforated the spleen, left kidney and transverse mesocolon. The spleen and kidney were removed and the rent in the mesocolon repaired. After three weeks the bullet was removed from the lumbar muscles. Convalescence was uneventful.

Thromocytopenic purpura is a disease which responds to splenectomy. Characterized by excessive bleeding beneath the skin, from the nose, from the bowel, from the genito-urinary tract, or from any skin laceration or needle puncture, these patients frequently become very anemic and the hemorrhages are at times uncontrollable. Before treatment by splenectomy the disease was at times fatal. The diagnosis is made from the history and findings as noted above and the presence of a low blood platelet count. This count may have dropped from a normal of 200,000 plus to 35,000 or even as low as 2000. As soon as the diagnosis is made, splenectomy should be performed, as treatment by transfusion or intramuscular injections of blood only gives at best only temporary relief.

The case of P. T. was a child of eighteen months of age, whose parents gave the history of a sudden generalized ecchymosis which continued for four days but cleared spontaneously in ten days under treatment with calcium. A second episode occurred at the age of two years and four months, which cleared up following the injection of coagulose, but a large hematoma occurred at the injection site. Her platelet count was 75,000. She cleared again and had no recurrence until the age of six years when another attack occurred. This was in September and October of 1927. During this attack seventeen platelet counts were done. The highest count was 33,000 and the lowest was 10,000. On October 18, 1927, splenectomy was performed. All bleeding ceased, and at 3:00 p.m. on the day of surgery the platelet count rose to 38,000. The patient was discharged October 31, 1927, considerably improved. She has had no recurrence since and is now twenty-nine years old, and in November, 1949, her platelet count was 175,000.

There is also the case of Mrs. M. W., who was first seen February 6, 1941, at the age of forty-seven with typical petechial hemorrhages and melena. Platelet counts taken at intervals for the next seven months varied from 215,000 down to as low as 2000. It is significant that the hemorrhages and the low platelet counts coincided. On September 27, 1941, splenectomy was performed. Convalescence was uneventful and on November 17, 1941, two months after operation, her platelet count was 250,000. However her platelets have not always remained up and have been as low as 7000 since her operation, but in spite of this she has never had a recurrence of hemorrhage. We suppose an accessory spleen could account for this.

Congenital hemolytic jaundice is another disease which responds to splenectomy. This condition frequently occurs in several members of a family and is characterized by mild jaundice and secondary anemia. Symptoms are usually due to the anemia. Enlargement of the spleen occurs early, and gallstones are a frequent complication. The diagnosis is confirmed by the presence of increased fragility of the red blood cells in hypotonic salt solution. On the other hand acquired hemolytic jaundice usually does not respond to splenectomy and usually does not show increased fragility of the red blood cells. Treatment in the acquired type should be directed at the underlying cause of the jaundice. If this is removed, the jaundice will clear up. In true congenital hemolytic jaundice the response to splenectomy is spectacular when the red-blood-cell-destroying spleen is removed. The increase in the red blood count is immediate almost before the operation is completed. Operation should be performed immediately even in the face of the poor condition of the patient as it offers the only cure.

The case of J. C. was a twenty-seven-year-old-boy admitted to the hospital January 17, 1942, complaining of weakness and a yellow pallor of his skin. He was extremely ill. His hemoglobin was 22 per cent, red blood count 986,000, white blood count 11,450. His red blood cells showed increased fragility to hypotonic salt solution. His spleen was palpable. Splenectomy was performed January 18, 1942, in spite of his poor condition. Citrated blood was given during the operation. Two hours after the operation his red blood count had risen to 1,750,000 and his hemoglobin to 38 per cent. Part of this rise was no doubt due to his transfusion but if the spleen had not been removed his transfused blood would not have been maintained. He left the hospital twelve days following operation, and in May, four months later, his hemoglobin was 85 per cent and his red blood count was 4,230,000. He has remained well since.

Panhematocytopenia and splenic neutropenia are primary hypersplenic conditions that have been sifted out of the catch-all of splenic anemia. In fact the differentiation between panhemotocytopenia and splenic neutropenia is so confusing that they are considered at times as varying degrees of the same disease. Bone marrow studies are essential as a prognostic factor in determining the advisability of splenectomy. Where the laboratory studies of the bone marrow show a myeloid hyperplasia and a normal or increased number of granulocytes which do not reach the blood and also a destruction of the erythrocytes, and at times a low platelet count, splenectomy is indicated and gives a good result.

The case of J. N. B. was that of a seventy-five-year-old man who in March, 1938, was found to have an abnormal blood count with his hemoglobin 9.8 grams, red blood count 2,500,000 and a white blood count of 2,200 of which 767 were granulocytes. Repeated counts remained approximately the same and transfusions were the only means by which his hemoglobin could be maintained. Another count showed his hemoglobin to be 6.8 grams, red blood count 1,800,000 and white blood count 1,700. His platelet count was 160,000. His spleen was palpable. Bone marrow studies showed myeloid hyperplasia, increased erythropoiesis. A diagnosis of panhematocytopenia was made on a hypersplenism basis.

His spleen was removed on October 28, 1949. One month later his hemoglobin was 11.9 grams, his red blood count 4,390,000, and his white blood count 4,200 with 47 per cent granulocytes. His platelet count was 242,000.

Felty's syndrome is another splenic condition which has characteristics of splenic neutropenia and panhematocytopenia, secondary anemia and a low platelet count with splenomegaly. However, associated with these findings are painful joints due to arthritis deformans, skin pigmentation and generalized adenopathy. At times an associated thrombocytopenic purpura may be present. We have never operated upon a patient with this syndrome but have had one under observation since November, 1949. At no time did her complaints seem to justify operation.

The case of Mrs. J. P. D. was that of a forty-eight-year-old, white woman who was admitted to the hospital on November 8, 1949, complaining of nausea, vomiting and abdominal pain. She had been in her usual state of health until November 6, 1949, when she first noticed crampy abdominal pain following a meal of sauerkraut and spareribs. During the interval between onset of pain and admission she had several bouts of emesis. Bowels moved normally twice the day before admission. She had had a previous episode in August, 1949, which cleared up without medical attention. Past history revealed that she had had rheumatoid arthritis with severe deformities of hands and arms for approximately twenty years, a myomectomy and uterine suspension in 1934, and a subtotal hysterectomy in 1943. Examination on admission revealed a white woman in considerable pain. Her hands showed typical rheumatoid deformities and she was unable to extend her elbows. Her tongue was smooth, red and dry. The left lobe of her thyroid was somewhat enlarged. The abdomen was mildly distended and there was voluntary muscle guarding present. Tenderness was present in both lower quadrants. Bowel sounds were active but not high pitched. The spleen could not be palpated but x-ray examination revealed splenomegaly and small bowel distention. Blood pressure was 130/80, pulse rate 100, temperature 100.2. Blood counts on ten successive days revealed an average hemoglobin of 11 grams. Red blood counts averaged 3,500,000 and white blood counts averaged 3,000, the lowest being 2,200. There was an increase in the granulocytes, averaging about 80. Her platelet count was 120,000. Fragility test was normal. Bone marrow studies showed a myeloid hyperplasia. Her abdominal symptoms disappeared under intravenous medication and enemata and nasal suction. This patient, we believe, has a typical mild Felty's syndrome, and splenectomy is being considered if she has any recurrence of her abdominal complaints or if her blood picture changes progress. We do not feel, however, that it will affect her rheumatoid arthritis.

There are several other conditions associated with diseases of or enlargement of the spleen which respond to surgical treatment better than to medical. We mention them here so as to complete the record of surgical conditions of the spleen even though we have had no personal experience in cases of this kind. They, if encountered, should be given surgical consideration. Cole, Walter and Limarzi mention some of them.

Thrombosis or anomalous obstruction of the splenic vein may be reason for splenectomy. We appreciate that some of these cases may be early, ill-defined cases of Banti's disease. The diagnosis is made by the finding of splenomegaly, secondary anemia, leukopenia and thrombopenia. This condition no doubt was also included under the old splenic anemia group at one time. Hemorrhage from the gastrointestinal tract may be present, arising from esophageal varices which can at times be identified in roentgenograms. The consensus of opinion is that where obstruction of the vein exists primarily and no other complicating factors are present, splenectomy will cure. This no doubt accounts for some cures in so-called early Banti's disease where no liver damage or complications are present. The other group where the portal block is intrahepatic, such as in cirrhosis of the liver or advanced Banti's disease, no result can be obtained. The resulting portal hypertension has given rise to numerous procedures for its relief. Splenectomy will relieve or cure in early cases where the pathology is primarily an extrahepatic block in the portal vein itself. Nature tries to establish collateral circulation by dilating veins of the falciform ligaments, the veins of the cardia connecting with azygos and diaphragmatic veins, the hemorrhoidal veins and through veins of the retroperitoneal glands and appendages. Procedures other than splenectomy have been tried, some with some success at times. Talma devised anastomoses of various intra-abdominal organs, principally the omentum to the abdominal wall and between the liver, spleen and diaphragm and the anterior abdominal wall. Anastomosis of the superior mesenteric vein to the caval circulation was tried by Bogaras. Learmonth anastomosed the splenic vein to the left renal vein after splenectomy and nephrectomy with indifferent success and a surgical mortality of 33 per cent in fifteen cases. At any rate he has now discontinued the procedure. Ligation of some gastric arteries has been tried. Gastric resection has been tried by Wagensteen with a 50 per cent operative mortality and uncertain results.

So we think it may be concluded that good results will be obtained in early extrahepatic portal obstruction with portal hypertension by splenectomy. Uncertain results in late cases is the rule where blood diverting operations of any type are tried, and these procedures carry a high operative mortality. We have had no personal experience with any other surgical procedure other than splenectomy for this condition.

Cysts of the spleen, abscesses or parasitic invasion of the organ, Gaucher's disease and even simple ptosis may at times occur which, if giving symptoms, should be treated by splenectomy. All of these conditions are rare.

Conclusions

1. We have attempted to summarize the conditions for which splenectomy has been tried and found worthless or for which some other procedure has been developed which has been proven superior.
2. We have summarized the conditions which splenectomy palliates.
3. We have presented the conditions in which splenectomy cures or gives good results.

Minneapolis Surgical Society

Meeting of April 6, 1950

The President, Ernest R. Anderson, M.D., in the Chair

VAGOTOMY IN THE TREATMENT OF PEPTIC ULCER

FREDERICK M. OWENS, JR., M.D., F.A.C.S.
Saint Paul, Minnesota

TEN to 20 per cent of patients with peptic ulcer are referred to the surgeon for the treatment of some complication of the ulcer. The complications for which surgical treatment is sought are: (1) perforation, (2) hemorrhage, (3) pyloric stenosis, (4) intractible symptoms. In general, the choice of operation lies between gastric resection and vagotomy for these cases. It is not my intention to discuss the pros and cons of the two operations, but to present the results of a group of vagotomies done at the University of Chicago.

The discussion will be limited to the treatment of duodenal ulcer, for when operation is undertaken for gastric ulcer, there are definite advantages to gastric resection. The good results from vagotomy in the treatment of jejunal ulcer are recognized by even the most severe critics of the procedure; thus there is little indication for including this category in the discussion.

There are three groups of patients in which I feel vagotomy has distinct advantage over gastric resection; these are herein enumerated. First, the patient who has difficulty maintaining his normal weight, or the asthenic patient, is an excellent candidate for vagotomy inasmuch as following vagotomy such a patient is better able to maintain his weight or to gain weight than after gastric resection. Weight record studies in both groups of pations have borne out this contention quite consistently. Second, the patient with a severely scarred duodenum can be treated with a lower mortality and morbidity by vagotomy than by gastric resection. Admittedly, the antral exclusion operation may be done in these cases, but the mortality and morbidity in the group is significantly greater than with vagotomy. This is true, in general, of the difference in the morbidity and mortality between gastric resection and vagotomy, as will be discussed later. Third, the patient who is a problem insofar as his personality make-up is concerned tends to develop rather severe symptoms following operation. This patient may be considered for vagotomy and gastroenterostomy as he is less likely to develop severe disturbances after this operation than after gastrectomy.

During the past few years there has been considerable discussion as to the detrimental effects produced upon the other abdominal viscera by vagotomy, but all such fears are unfounded. Thorough study of the viscera of three patients who died many months following vagotomy have failed to reveal any microscopic evidence of change in the duodenum, jejunum, ileum, colon, kidneys, liver, pancreas or adrenals. These organs were considered to be completely normal by microscopic examination. Furthermore, when gastrectomy is carried out, there is effected a vagotomy of varying degree. Following total gastrectomy or esophagogastrectomy or esophagectomy there results a complete vagotomy. Certainly no one has demonstrated any concern as to the effect of these operations on the abdominal viscera.

The physiology of vagotomy is well understood at the present time. Suffice it to say that there is a decrease of total volume of gastric secretion, a decrease of the acid output of the stomach, and a decrease of the tonus and motility of the stomach.

As first described by Dragstedt,[1] the operation was done transthoracically, but at the present time the majority of the operations are being done transabdominally. Not only does the abdominal route permit examination of the ulcer area and other abdominal viscera, but it allows for more complete division of the vagus nerves. At the same time a gastroenterostomy may be done to facilitate drainage of the stomach. At least 20 to 25 per cent of patients having vagotomy require accessory drainage of the stomach either at the time of the vagotomy or at a later date. At the present time it is my feeling that gastroenterostomy should be done in all cases of vagotomy, and I believe that the results in this group of patients will bear out this contention.

The technique of operation employed is to enter the abdominal cavity through a high left paramedian incision. The viscera are explored, and then the triangular ligament of the left lobe of the liver is exposed by the surgeon and cut by his assistant so that the left lobe can be retracted well to the right. The left lobe is then held out of the field with a stockinette covered Deaver or Harrington retractor. The esophagus is identified by palpation, and an incision is made in the peritoneum across the lower portion of the esophagus. This incision is enlarged bluntly, and the index finger is inserted into the mediastinum behind the esophagus. Gradually the exposure is increased so that it is possible to insert the index and middle fingers behind the esophagus and all adventitious tissue is brought toward the esophagus with the fingers while working higher and higher into the mediastinum. Finally, it is possible to bring at least three inches of esophagus down out of the mediastinum. The vagus nerves are felt as tight strands, resembling violin strings, along the esophagus. The nerves are picked up as high as possible and dissected distally, then clamped and ligated as high as possible. A segment of nerve an inch or two in length is then removed and the distal transected ends are ligated. Meticulous search is made for additional vagus fibers along the esophagus and also in the mediastinum.

TABLE I. CLASSIFICATION OF RESULTS

Good—healing of the ulcer, patient asymptomatic, return to previous occupation or its equivalent.
Fair—healing of ulcer, but distressing symptoms such as late chest pain, bowel distress, mild obstructive symptoms, or mild diarrhea.
Poor—recurrence of ulcer, severe obstructive symptoms, disabling side effects such as dumping or protracted diarrhea; death.

When one is satisfied that he has divided all possible fibers, the opening in the peritoneum is carefully closed with interrupted sutures and the left lobe of the liver is fixed in place by suturing the divided triangular ligament. At this point a small gastroenterostomy is made between the posterior wall of the stomach and the first part of the jejunum. This is a retrocolic anastomosis and should measure 2.5 to 3 centimeters in length. A small gastroenterostomy stoma is advisable for reducing the likelihood of dumping symptoms.

The postoperative management of the patient following vagotomy is important. Constant gastric suction is maintained for three or four days; then the tube is removed, and during the first day without the tube the patient is allowed 30 c.c. of water every hour. He is aspirated at night to determine the presence of retention, if any. In the absence of retention the patient is allowed 60 c.c. of water an hour the second day after withdrawal of the tube and is again aspirated at night. The third and fourth days clear liquids are given ad lib. The fifth and sixth days six feedings of full liquid are given and the stomach is aspirated once at night to determine retention. The seventh and eighth day six feedings of soft diet are given. The ninth day clear liquids are given and a twelve-hour secretion test is run at night, and in the morning before removal of the tube, an insulin gastric secretion test is carried out. The patient is discharged on the tenth day and instructed that he should not allow his stomach to become distended. His diet is restricted to readily digestible foods for three weeks after discharge. Another insulin gastric test is done three months after discharge from the hospital.

The clinical results of the operation are classified according to the outline in Table I.

An ulcer was not classified as healed unless there was roentgenographic evidence of healing and freedom from ulcer symptoms. Table II classifies the results according to the type of operation performed.

There is definite superiority of the results in the group treated by vagotomy and gastroenterostomy over the other groups.

In the transthoracic group those patients considered as fair results were patients whose ulcers healed, but who continued to have mild symptoms of delayed emptying of the stomach. These symptoms were distressing, but not disabling. The poor results in this group include one death, six cases of recurrent ulcer, and six cases of obstruction severe enough to warrant operation. Five patients had gastroenterostomy with good result, one with fair result.

In the group of patients operated upon via the abdominal route who had vagotomy without any adjunct operation, the fair results are listed as two cases with diarrhea, one case with what is described as "dumping," and sixteen cases with mild obstructive symptoms. Those classified as poor results include three deaths, eleven recurrent ulcers and ten patients who underwent subsequent gastroenterostomy for obstruction (eight with good results and two with fair results), and one case with severe obstruction who refused gastroenterostomy for a long time and later had partial gastrectomy elsewhere.

TABLE II. RESULTS IN 465 VAGOTOMIES FOR DUODENAL ULCER

Transthoracic vagotomy—57	
Good— 37—65%	
Fair— 7—12.2%	Mortality—1—(1.7%)
Poor— 13—22.8%	
Abdominal vagotomy—148	
Good—104—70.2%	
Fair— 19—12.8%	Mortality—3—(2.0%)
Poor— 25—17.0%	
Abdominal vagotomy and gastroenterostomy—260	
Good—239—91.9%	
Fair— 11— 4.2%	Mortality—1—(0.38%)
Poor— 10— 3.9%	

Finally, in the group having vagotomy via the abdominal route and gastroenterostomy, there were eleven fair results (4.2 per cent), with four patients having "dumping," one being a drug addict, four having bowel distress, and two patients having mild diarrhea. In the poor result category there was one death, one Mann-Williamson ulcer; five recurrences of ulcer—one had second operation with lysis of adhesions and subsequently a fair result. One patient was re-explored for persistent symptoms and a duodenal diverticulum was removed with good results. One patient subsequently had hemorrhage of undetermined origin.

The statistics in this group of patients are self-explanatory, and it should be noted that the over-all mortality rate was 1.3 per cent. In the group of patients with vagotomy and gastroenterostomy the mortality rate was 0.38 per cent in a group of 260 patients. The results with this operation in the treatment of duodenal ulcer have been satisfactory; the mortality and morbidity has been low, and the clinical course of the patients such as to justify its continued use.

Summary

1. A group of 465 patients treated for duodenal ulcer by vagotomy alone or in conjunction with gastroenterostomy is presented.

2. A comparison between the results of operation in three different categories is made. The categories represent the type of operation, i.e., transthoracic, transabdominal, or transabdominal with gastroenterostomy.

3. The superiority of the results in the group with abdominal vagotomy and gastroenterostomy is significant.

4. The results suggest that this operation has a definite place in the treatment of duodenal ulcer.

✦ Reports and Announcements ✦

AMERICAN COLLEGE OF CHEST PHYSICIANS

A postgraduate course in diseases of the chest, sponsored by the Council on Postgraduate Medical Education and the Southern Chapter of the American College of Chest Physicians, will be held at Vanderbilt University School of Medicine, Nashville, Tennessee, January 22 to 27. The fee for the course is $50. Further information can be obtained from the American College of Chest Physicians, 500 North Dearborn Street, Chicago 10, Illinois.

AMERICAN COLLEGE OF SURGEONS SECTIONAL MEETING

A cordial invitation is extended to physicians and surgeons in the State of Minnesota to attend a three-day sectional meeting of the American College of Surgeons in St. Louis on January 22, 23 and 24. The Statler Hotel will be headquarters for the meeting and requests for hotel accommodations should be directed to the Statler Hotel in St. Louis.

The program for this meeting will include new surgical motion pictures, a special program on trauma, a cancer symposium, and panels or papers on vascular surgery, chest injuries, fractures about the ankle joint, hematuria following trauma, neck surgery, osteomyelitis, ulcerative colitis, cancer of the stomach, and emergencies arising during operation. The first two days of the program will be presented at the headquarters hotel, and on January 24 the hospitals in St. Louis will offer a full day of surgical clinics for those in attendance at the meeting.

A $5 registration fee will be required, except from Fellows and members of the Junior and Senior Candidate Groups of the College, and interns and residents.

Additional information may be obtained by writing to Dr. James Barrett Brown, American College of Surgeons, 40 E. Erie Street, Chicago 11, Illinois.

AMERICAN DERMATOLOGICAL ASSOCIATION PRIZE ESSAY CONTEST

The American Dermatological Association is offering a prize of $300 for the best essay submitted of original work, not previously published, relative to some fundamental aspect of dermatology or syphilology. The purpose of this contest is to stimulate younger investigators to original work in these fields.

Manuscripts typed in English with double spacing as for publications, together with illustrations, charts and tables, are to be submitted in triplicate not later than February 1, and should be sent to Dr. Louis A. Brunsting, Secretary, American Dermatological Association, 102-110 Second Avenue, Southwest, Rochester, Minnesota.

Competition in this prize contest is open to scientists generally; not necessarily physicians.

The award will be made by a committee of judges selected to pass on the essays by the Research Aid Committee of the American Dermatological Association and the decision of the judges shall be final. This contest is planned as an annual one, but if in any year, at the discretion of the Research Aid Committee and judges, no paper worthy of a prize is offered, the award may be omitted.

The prize-winning candidate may be invited to present his paper before the annual meeting of the American Dermatological Association, with expenses paid in addition to the $300 prize. Further information regarding this essay contest may be obtained by writing to the secretary of the American Dermatological Association.

The next annual meeting of the American Dermatological Association will be the Diamond Jubilee Observance of its founding and will be held May 23 to 26, 1951, at the Homestead, Hot Springs, Virginia.

CLEVELAND HEART SOCIETY

A practical course for resuscitation of patients in the operating room will be presented in Cleveland January 25 to 27, February 15 to 17, and March 15 to 17 by Dr. Claude S. Beck under the sponsorship of the Cleveland Heart Society.

Those interested, surgeons and anesthetists particularly, may contact Mrs. Jerry H. Bruner, executive secretary, Cleveland Heart Society, 613 Public Square Building, Cleveland 13, Ohio.

NEW ORLEANS GRADUATE MEDICAL ASSEMBLY

The fourteenth annual meeting of the New Orleans Graduate Medical Assembly will be held March 5 to 8, with headquarters at the Municipal Auditorium, New Orleans.

Nineteen outstanding guest speakers will participate, and their presentations will be of interest to both specialists and general practitioners. The program will include a panel discussion on ACTH and cortisone, a series of talks on trauma and neoplastic disease, a review of the application of radio-active isotopes in medical practice, clinicopathologic conferences, round-table luncheon discussions and many other features.

Another feature of the meeting will be daily demonstrations of medical and surgical procedures in color television. This program will be a telecast from Charity Hospital to the auditorium.

The Assembly has planned a postclinical tour to follow the 1951 meeting. On March 10 a party composed of doctors and their families will leave by plane for Panama. The itinerary also includes Medellin and Cali, Colombia; Quito, Ecuador, and Lima, Peru. Medical programs and visits to hospitals have been arranged, together with a full schedule of sightseeing. The group will return to New Orleans on March 25. Details and a complete itinerary are available at the office of the Assembly, Room 103, 1430 Tulane Avenue, New Orleans 12, Louisiana.

"*A high percentage of cases of seasickness and carsickness can be aborted or prevented by suitable doses of dimenhydrinate (Dramamine).*"

—Council on Pharmacy and Chemistry, New and Nonofficial Remedies, J.A.M.A. *143*:815 (July 1) 1950.

DRAMAMINE® Brand of Dimenhydrinate—for the prevention or treatment of motion sickness—is supplied in 50 mg. tablets and in liquid form.

RESEARCH IN THE SERVICE OF MEDICINE SEARLE

Announcing

THE FOURTEENTH ANNUAL MEETING

of

THE NEW ORLEANS GRADUATE MEDICAL ASSEMBLY

Conference Headquarters—Municipal Auditorium
March 5-8, 1951

GUEST SPEAKERS

Dr. Theron G. Randolph, Chicago, Ill.
Allergy
Dr. Marshall Brucer, Oak Ridge, Tenn.
Atomic Medicine
Dr. Donald M. Pillsbury, Philadelphia, Pa.
Dermatology
Dr. Jerome W. Conn, Ann Arbor, Mich.
Endocrinology
Dr. H. Marvin Pollard, Ann Arbor, Mich.
Gastroenterology
Dr. John L. McKelvey, Minneapolis, Minn.
Gynecology
Dr. Arlie R. Barnes, Rochester, Minn.
Medicine
Dr. Cornelius P. Rhoads, New York, N. Y.
Medicine
Dr. George S. Baker, Rochester, Minn.
Neurosurgery

Dr. Newell W. Philpott, Montreal, Can.
Obstetrics
Dr. John M. McLean, New York, N. Y.
Ophthalmology
Dr. Harold A. Sofield, Chicago, Ill.
Orthopedic Surgery
Dr. Henry B. Orton, Newark, N. J.
Otolaryngology
Dr. Stanley P. Reimann, Philadelphia, Pa.
Pathology
Dr. Albert V. Stoesser, Minneapolis, Minn.
Pediatrics
Dr. Paul C. Hodges, Chicago, Ill.
Radiology
Dr. Nathan Womack, Iowa City, Ia.
Surgery
Dr. Charles S. Welch, Boston, Mass.
Surgery

Dr. Austin I. Dodson, Richmond, Va.
Urology

Lectures, symposia, clinicopathologic conferences, round-table luncheons, surgical and medical procedures in color television and technical exhibits (All-inclusive registration fee—$15.00)

The Postclinical Tour to Panama, Colombia, Ecuador and Peru—March 10-25

For information concerning the Assembly meeting and the tour, write Secretary, Room 103, 1430 Tulane Avenue, New Orleans 12, La.

AMERICAN MEDICAL WRITERS' ASSOCIATION

The eighth annual meeting of the American Medical Writers' Association will be held at the Pere Marquette Hotel, Peoria, Illinois, September 19 during the sixteenth annual meeting (September 19, 20, 21) of the Mississippi Valley Medical Society in that city.

The association will publish its 1951 membership booklet in February and is desirous of securing as members all physicians interested in any phase of medical writing. Any AMA member who has published two ore more articles, indexed by the *Quarterly Cumulative Index Medicus*, is eligible for membership. Further details may be secured from the secretary, Dr. Harold Swanberg, 510 Maine Street, Quincy, Illinois.

MISSISSIPPI VALLEY MEDICAL SOCIETY ESSAY CONTEST

The eleventh annual essay contest of the Mississippi Valley Medical Society will offer a cash prize of $100, a gold medal, and a certificate of award for the best unpublished essay on any subject of general medical interest, including medical economics and education. Contestants must be members of the American Medical Association who are residents and citizens of the United States. The winner will be invited to present his contribution at the sixteenth annual meeting of the Mississippi Valley Medical Society to be held in Peoria, Illinois, September 19, 20, 21, 1951. All contributions must be typewritten in English in manuscript form, submitted in five copies, not to exceed 5,000 words, and must be received not later than May 1.

Further details may be secured from Dr. Harold Swanberg, secretary, Mississippi Valley Medical Society, 209-224 W.C.U. Building, Quincy, Illinois.

CONTINUATION COURSE

The University of Minnesota announces a continuation course in ophthalmology for physicians specializing in this field. The course will be presented at the Center for Continuation Study, January 22 to 26. Dr. Alson E. Braley, professor and head of the Department of Ophthalmology, University of Iowa, and Dr. A. D. Ruedemann, professor and head of the Department of Ophthalmology at Wayne University, Detroit, will be the visiting faculty members for the course. Staff members of the Mayo Foundation and University of Minnesota Medical School will complete the faculty for the course. The course is given under the direction of Dr. Erling W. Hansen, clinical professor of Ophthalmology and director of the Division of Ophthalmology.

"...*in the minds of men*..."

In treating the disorders that exist in the minds of men, psychiatric nursing plays a vital role. Proper care can be given patients only by properly trained psychiatric nurses.

In view of the present shortage of such trained nurses, and the desperate need for them, the Glenwood Hills Hospitals School of Nursing, Neurology and Psychiatry is appealing to you physicians for aid in solving this problem.

By sending us the name of a promising nursing candidate in your community—a girl aged seventeen or over, with a high school education—you will be doing your part to alleviate this critical nursing shortage.

Our one-year course in psychiatric nursing is tuition-free. Our graduates have an excellent professional career before them.

Please send the name of a potential nursing recruit to

GLENWOOD HILLS HOSPITALS
3501 GOLDEN VALLEY ROAD
MINNEAPOLIS 22, MINNESOTA

ANNUAL CLINICAL CONFERENCE

CHICAGO MEDICAL SOCIETY

March 6, 7, 8, 9, 1951 • Palmer House, Chicago

A conference planned to keep physicians abreast of the new things which are developed from year to year.

Special feature of the 1951 Conference—DAILY TEACHING DEMONSTRATION PERIODS from 11:00 to 12:00 noon and 1:30 to 3:00 P.M. Demonstrations will cover:

- Amputations and Prostheses
- Patients Treated with ACTH and Cortisone
- Dermatologic Clinic
- Organization of a Blood Bank
- Neurological Clinic
- Sterility Tests
- Speech Without Larynx
- Proper Application of Casts and Splints in Fractures
- Local Anesthesia
- Fluid and Electrolytic Balance in Surgery
- Use and Misuse of Obstetrical Forceps
- Common Problems in X-Ray Interpretations
- Laboratory Tests (Diabetes, Proper use of Insulin, Prothrombin Tests)

Thirty-four outstanding teachers and speakers will present half-hour lectures on subjects of interest to both general practitioner and specialist.

Four PANELS on timely topics

Scientific exhibits worthy of real study and helpful and time-saving technical exhibits.

The CHICAGO MEDICAL SOCIETY ANNUAL CLINICAL CONFERENCE should be a MUST on the calendar of every physician. Plan now to attend and make your reservation at the Palmer House.

(Continued from Page 1254)

MINNESOTA SOCIETY OF INTERNAL MEDICINE

At the annual meeting of the Minnesota Society of Internal Medicine at Rochester on October 30, Dr. A. E. Brown of Rochester was elected president of the organization. He succeeds Dr. Frederick H. K. Schaaf, Minneapolis, in the office. Also named as officers were Dr. Sam Boyer, Jr., Duluth, vice president, and Dr. Robert L. Parker, Rochester, secretary-treasurer.

SAINT PAUL SURGICAL SOCIETY

The Saint Paul Surgical Society held its regular meeting at the Minnesota Club, Saint Paul, on November 15. The principal speaker of the evening was Dr. Richard A. Telinde, chief of gynecology at Johns Hopkins University, Baltimore, who discussed "Endometriosis."

SOUTHWESTERN MINNESOTA MEDICAL SOCIETY

At the annual meeting of the Southwestern Minnesota Medical Society at Pipestone on October 30, Dr. P. J. Pankratz of Mountain Lake was elected president of the organization. Other officers named were Dr. S. S. Chunn, Pipestone, president-elect; Dr. W. B. Wells, Jackson, vice president, and Dr. O. M. Heiberg, Worthington, secretary-treasurer.

The principal speaker at the meeting was Dr. A. H. Wells, Duluth, who discussed the value of having the services of a pathologist in the southwestern Minnesota area.

Woman's Auxiliary

PRESIDENT URGES MEMBERSHIP DRIVE

Mrs. Charles W. Waas

It is not my intention at this time to give you a report on the Conference of Presidents held in Chicago last month from which I have just returned. However, there are some suggestions which I should like to pass on to you. First, I should like to tell you that there were only five presidents who were absent. It was thrilling to be a part of such a large group of presidents and their presidents-elect, and our national president, Mrs. Herold, was so appreciative of the large attendance. Our own Mrs. Wahlquist, national president-elect, presided at the two-day session. We are justly proud of her.

Membership in a medical auxiliary is a privilege extended to us by our husbands. Why, then, are there so many doctors' wives in our own state who do not belong? Is it the fault of auxiliary members? Have we extended a truly friendly invitation? The cost of membership is so small that it never enters into the question. Increased membership is one of our greatest aims this year. Won't you do your share? Don't forget the doctors' wives who live in counties where there are no auxiliaries. Members at large are invaluable. Our parent organization is eager to have them. Ask them to join now and then invite them to attend your next meeting. Here let me say that at the next state board meeting which will be held in Minneapolis, probably during the month of January, all members of the state auxiliary will be most welcome. It will not be confined to board members. Invite new members to attend with you.

In your drive for subscriptions to *Today's Health,* have you thought about contacting young mothers? There is a wealth of information in this authentic magazine for them, and when they become acquainted with it they will surely want to carry on their subscription year after year. We are neglecting our friends and neighbors if we deprive them of the opportunity of reading this worthwhile periodical. Have you thought about giving subscriptions for gifts? Perhaps in your community there are mothers of families who would be happy to receive such a gift. A copy of the magazine should be found in every doctor's reception room, in every high school, community center, club, beauty shop, barber shop and countless other stations. There is room for much improvement. Won't you do your share?

What kind of programs have you planned? Sometimes during membership drives we are told that our programs are not interesting. Why aren't they? There are many suggestions for programs, many films and much literature to be had for the asking. Have your program chairmen contact our state program chairman and with her help, you can have a splendid program at every meeting. Plan one or two meetings to which you can invite your lay friends.

Public relations! Every doctor's wife should be a committee of one! We have a marvelous opportunity to spread the truth and clarify matters for lay people. Our husbands have met the challenge hurled at them and they are fighting honestly and fearlessly for the American way of life. Auxiliary members—be well informed! Do your share!

DRIVE STARTED TO COLLECT SAMPLE DRUGS

Mrs. Bernard E. O'Reilley, Chairman
Committee on Medical and Surgical Relief

Sample drugs received in doctors' offices can help fill the need of many institutions whose budgets don't allow purchase of many of these drugs. Auxiliary members are urged to arrange to spend a few hours twice or more a year to collect the sample drugs. Members should ask their husbands to save these drugs for collection. Office girls will be glad to have a box or large paper bag placed in the office for the samples. The orphanages, rest homes, county homes, missionary societies throughout the state will welcome boxes of drugs for distribution. Auxiliary members are asked to start now saving the samples for this worthwhile work. In the next issue of MINNESOTA MEDICINE the names of organizations that will accept instruments and drugs for shipment overseas will be listed.

Drugs may be separated into groups, such as vitamins, baby foods, salves, headache medicine, et cetera. Don't let valuable drugs be wasted.

PROMINENT AUXILIARY MEMBER DIES

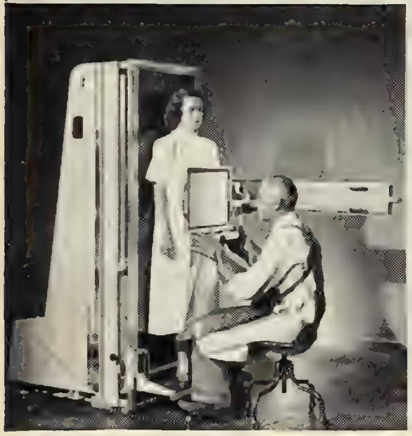
Mrs. William J. Byrnes died in Minneapolis October 21, 1950. Mrs. Byrnes was the widow of Dr. William J. Byrnes, who died in November, 1929. Dr. Byrnes was of a pioneer family, coming from New York in 1851.

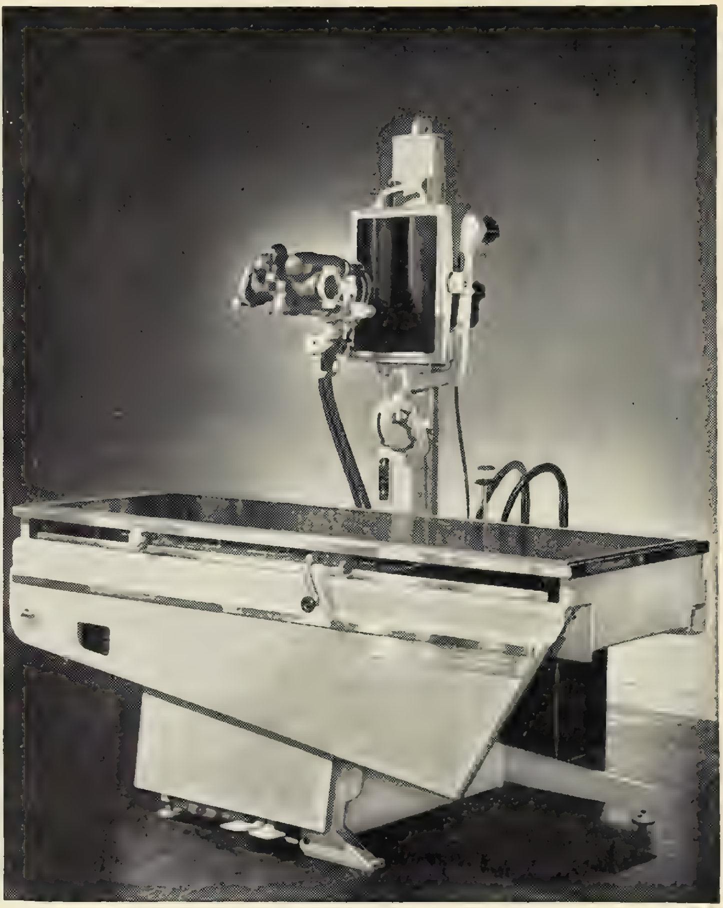
Mrs. Byrnes was the organizing president of Hennepin County Medical Auxiliary in October, 1910. She has held the office of parliamentarian several times for the Woman's Auxiliary to the Minnesota State Medical Association.

She was a life member of the Minnesota Historical Society, a member of the Minneapolis Woman's Club, the Lewis Parliamentary Law Club, the American Legion Auxiliary and the Oak Park Study Club. She is survived by three daughters: Miss Lyle Byrnes, Mrs. Hallan Huffman, and Mrs. Robert Seiberlich.

The experience of two great wars and studies of the mortality figures of tuberculosis in relation to environment have shown that when the standard of living falls tuberculosis rises.—FREDERICK HEAF, *British Medical Journal,* November 5, 1949.

NOW... a single-tube Maxicon combination unit with table-mounted tube stand





COMPONENT construction now makes available a new combination table in the expansive Maxicon line of diagnostic x-ray apparatus. Hand-tilt or motor-driven, this single-tube radiographic and fluoroscopic table is designed for operation with 100 or 200 ma equipment, usually with the matching control stand illustrated. Its table-mounted tube stand makes it so compact it will fit in a small room.

Discover for yourself the remarkable flexibility of the Maxicon. Ask your GE representative for unique booklet demonstration, or write.

In Memoriam

JOHN PHINEAS BARBER

Dr. John P. Barber, a Minneapolis physician for more than fifty years, died October 13, 1950, at the age of ninety-three.

Dr. Barber was born near Bardstown, Kenutcky, October 27, 1857. He graduated from Cecilian College in 1881 and from the University of Louisville Medical School in 1886. He interned at SS. Mary and Elizabeth Hospital in Louisville, after which he moved to Minneapolis.

He was a member of the Hennepin County Medical Society, the Minnesota State Medical Association and the American Medical Association, the Knights of Columbus, the Sons of the American Revolution and the Hibernians.

Surviving are his wife, Alice W., five sons and five daughters.

GUSTAF WILLIAM DAHLQUIST

Dr. G. W. Dahlquist, formerly of Lancaster, Minnesota, died October 25, 1950, at the Minnesota Soldier's Home. He was eighty-six years of age.

Dr. Dahlquist obtained his M.D. degree at the University of Minnesota in 1893 and practiced at Lancaster, Minnesota, from 1907 to 1917 when he enlisted in the Army. After World War I, he returned to Lancaster and several years later went to Fargo, North Dakota, where he was on the medical staff of the Veterans Administration for ten years.

Mrs. Dahlquist passed away last winter. Dr. Dahlquist is survived by six children.

ALEXANDER G. DUMAS

Dr. Alexander G. Dumas, Chief of the Neuropsychiatric Service, Veterans Administration Facility, Minneapolis, Minnesota from 1922 to 1944, died October 2, 1950.

Dr. Dumas was born in Minneapolis, May 11, 1896. He obtained a B.S. degree from St. Thomas College in Saint Paul in 1916, and an M.D. from Creighton University Medical School, Omaha, Nebraska in 1921. After interning at St. Joseph's Hospital in Omaha, Nebraska, he took postgraduate study at the State Hospital for the Insane at Osawatomie, Kansas, for eighteen months. He was a veteran of World War I.

Dr. Dumas was a member of the Hennepin County Medical Society, the Minnesota State Medical Association, the American Medical Association, and the American Psychiatric Association. He was an Associate Professor of Psychiatry and Neurology in the University of Minnesota Medical School. He was one of the founders of the Governor's Advisory Committee on Mental Health and former chairman of that committee.

He was formerly Chief of Staff at Glenwood Hills and Homewood hospitals in Minneapolis, neuropsychiatric consultant to municipal courts in Hennepin County, medical director of Minnesota Mental Hygiene Society, Inc., and member of former Governor Stassen's crime commission.

Dr. Dumas married Octavia Dyke of Minneapolis in 1921. He is survived by his wife; a daughter, Mrs. Keith Brueckner, Princeton, New Jersey; three sons, James A., Cody, Wyoming, Frederick G., Stamford, Connecticut, and John C., Saint Paul; two grandchildren; his father, George A.; three brothers, Fred, Roy and Delbert, and one sister, Mrs. Kenneth Smith, all of Minneapolis.

Dr. Dumas was an outstanding leader in his field and an honor to his profession. His life was characterized by his devotion to his family and friends from all walks of life. His passing is a real loss to the medical profession and to the community.

I. GRANT DAVIS

Dr. I. Grant Davis, a practitioner at Rushford, Minnesota, until he sold his practice July 1, 1950, died at the home of Mr. and Mrs. Edward Reishus, Rushford, September 29, 1950.

Dr. Davis was born at Arcadia, Wisconsin, October 30, 1887. He obtained a B.S. degree from the University of Wisconsin in 1912 and an M.D. from Rush Medical College in 1914. His internship was served at La Crosse Lutheran Hospital at La Crosse, Wisconsin.

Dr. Davis practiced at Duluth in 1916, at Little Falls in 1917 and 1918, and served as a lieutenant in the Army in 1918 and 1919.

He was a member of the Olmsted-Houston-Fillmore-Dodge County Medical Society, the Minnesota State Medical Association and the American Medical Association. For many years he was health officer at Peterson and Rushford. He was active in the Masonic order, serving as secretary of the local lodge for many years.

Dr. Davis never married.

JOSEPH ELLSWORTH McCOY

Dr. J. E. McCoy, formerly of Ironton and lately of Thief River Falls, died September 22, 1950.

Dr. McCoy was born at Hillsboro, Ohio, February 4, 1870. He studied at Lebanon College in Ohio before attending Hospital College of Medicine at Louisville, Kentucky, where he graduated in 1897. In 1910 he came to Ironton, Minnesota, where he practiced until he moved to Thief River Falls in 1937.

In 1902 he married Clara Steiner, who died in 1929. Dr. McCoy married Julia Johnson in 1936. He is survived by Mrs. McCoy and two sons, Vernon of Minneapolis and Homer of Los Angeles.

Dr. McCoy was a former member of the Lyon-Lincoln Medical Society, the Minnesota State Medical Association and the American Medical Association.

Municipal Bonds and Inflation

The problem of inflation and its eventual effect upon an investor's savings was discussed in our last article by quoting from an address of Mr. Phillips Barbour, editor of the BOND BUYER, given before the Municipal Forum of the National Security Traders Association. The quotations below are from the same address under the section entitled, "How Municipals Fit Into the Picture."

(1) They are secure: Municipals are the only form of investment among those mentioned, that the investor can be as sure, as he can be about anything these days, that he will have his principal returned to him in full on a specified date in future.

(2) Income is dependable: With few exceptions among those mentioned, municipals alone, provide a regular income.

(3) They are the only income-producing investment in which the investor can know not only the number of dollars he will receive on a certain date, but how many of those dollars he may keep for himself to use as he wishes.

(4) There is opportunity for growth in market value of municipals, because as inflation grows taxes usually grow, as a result the value of the municipal income grows because it is tax-exempt. Thus, tax exemption tends to compensate for loss of purchasing power.

(5) Municipals are easy to buy or sell. Banks and brokers everywhere are accustomed to handling such transactions.

(6) They are an ideal collateral for making quick loans and banks are in no way restricted in making such loans.

(7) While municipals may not be bought blindly, the problem of picking a satisfactory investment in that category is simpler than in any other I know of, because the fundamental security underlying all municipals is substantially the same.

(8) Most municipals are paid out of taxes and taxes must be paid before dividends. Thus these securities have a prior claim, as it were, over dividends. When not paid out of taxes they are paid from revenues received for vital services rendered, such as sale of water, on which they have a monopoly."

We have reprints of Mr. Barbour's address available and will be pleased to send you one without obligation, upon request.

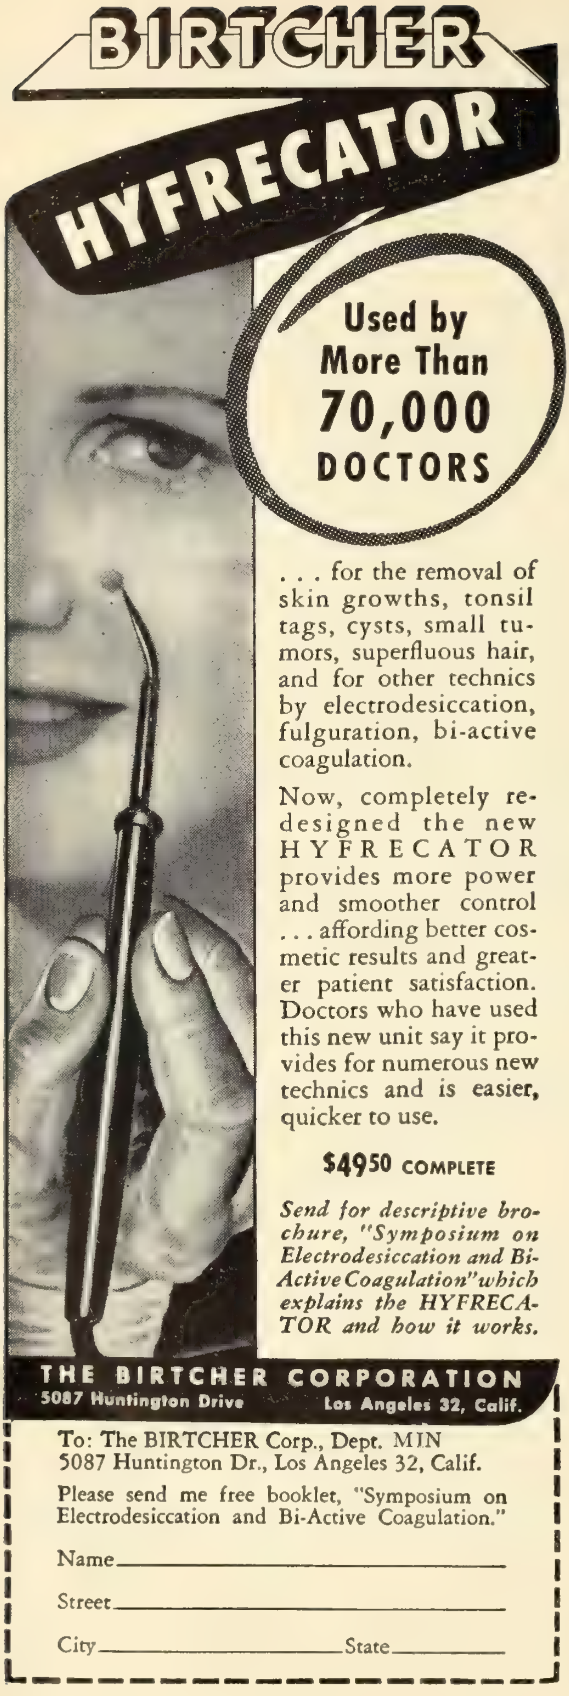
ERNEST S. MARIETTE

Dr. Ernest S. Mariette, who completed thirty-three years of service as superintendent of Glen Lake Sanatorium before his retirement, November 1, 1949, because of ill health, died October 29, 1950. He was sixty-two years of age.

Dr. Mariette was born January 3, 1888, in Blue Earth County. He graduated from the University of Minnesota Medical School in 1913 and interned at the University of Minnesota Hospital. From 1913 to 1916 he was on the staff of Nopeming Sanatorium.

Under his direction, Glen Lake Sanatorium, Hennepin County's hospital for the tuberculous, became nationally recognized as one of the great tuberculosis sanatoria of the United States. It was the first tuberculosis hospital in the country to receive a Class A rating from the American College of Surgeons.

A member of the board of directors of the National Tuberculosis Association, Dr. Mariette served as president of the Mississippi Conference on Tuberculosis, as president of the Minnesota Trudeau Society and, from 1946 through 1948, as president of the Hennepin County Tuberculosis Association. He was a member of the Hennepin County Medical Society, the Minnesota State Medical Association, the American Medical Association, and the American Hospital Association, and was an assistant professor of medicine at the University of Minnesota Medical School.



BIRTCHER HYFRECATOR

Used by More Than 70,000 DOCTORS

. . . for the removal of skin growths, tonsil tags, cysts, small tumors, superfluous hair, and for other technics by electrodesiccation, fulguration, bi-active coagulation.

Now, completely redesigned the new HYFRECATOR provides more power and smoother control . . . affording better cosmetic results and greater patient satisfaction. Doctors who have used this new unit say it provides for numerous new technics and is easier, quicker to use.

$49.50 COMPLETE

Send for descriptive brochure, "Symposium on Electrodesiccation and Bi-Active Coagulation" which explains the HYFRECATOR and how it works.

Many outstanding physicians in tuberculosis work were trained under his direction at Glen Lake Sanatorium. A special contribution of Dr. Mariette was his pioneer use of BCG vaccine in the protection of nurses and in initiating an in-sanatorium program for the rehabilitation of tuberculosis patients.

Dr. Mariette is survived by his wife, Anna; a son Sidney of Hopkins, and a daughter, Grace L. of Maplewood.

FRANK LYNAM

Dr. Frank Lynam, a resident surgeon at the Duluth shipyards during both World Wars, died at his home in Minneapolis, October 8, 1950. He was eighty-four years of age.

Dr. Lynam was a graduate of Bowdoin College and the Harvard Medical School. He was administrator of the American Relief Administration in Russia in 1922. At one time he was a member of the University of Michigan Medical School faculty and was a medical supervisor for the British in the Bahama Islands.

Surviving are his wife, Hazel, and two daughters.

WILLIAM ARNOLD MEIERDING

Dr. W. A. Meierding, who practiced in Springfield, Minnesota from 1911 to 1927 and in Mankato from 1927 to 1931, died October 12, 1950 in Corona, California, at the age of seventy.

Dr. Meierding was born at New Ulm, July 6, 1880. He graduated from the University of Minnesota Medical School in 1907 and interned at the Metropolitan Hospital in New York City and the Fergus Falls State Hospital.

In June, 1912, he married Alma Bendixen. They had two sons, William and Robert. During World War I, Dr. Meierding served as a lieutenant in the Medical Corps.

EDWIN ELMER SHRADER

Dr. E. E. Shrader, formerly of Winsted, Minnesota, died at Watertown, Minnesota, October 21, 1950. He was eighty-eight years of age.

Dr. Shrader obtained his medical degree from the University of Minnesota Medical School in 1893, and that same year began practice in Watertown. In 1928 he retired and moved to California. In 1935 he returned to Winsted, where he practiced until 1950. On January 22, 1950, on the occasion of his retiring from practice and moving to Watertown, he was tendered a farewell party by his many friends.

Dr. Shrader was a life member of the Wright County Medical Society, the Minnesota State Medical Association and the American Medical Association.

In a world in which co-operation on the political level seems at present an unrealizable dream, it is heartening to recall that it has existed for a long time in the field of health. Widespread public health is both an instrument and a condition of any lasting peace.—Dr. F. W. Behmler, *Minnesota's Health,* October, 1950.

◆ Of General Interest ◆

Thirteen Minnesota physicians were inducted into the **American College of Surgeons** at a meeting in Boston on October 27. The physicians are Dr. Charles F. Brigham, Jr., St. Cloud; Dr. Tague C. Chisholm, Minneapolis; Dr. Walter K. Haven, Minneapolis; Dr. Richard C. Horns, Minneapolis; Dr. Karl E. Johnson, Duluth; Dr. Malcolm R. Johnson, Minneapolis; Dr. Donald R. Lannin, Saint Paul; Dr. Donald P. McCormick, Minneapolis; Dr. Raymond K. Minge, Worthington; Dr. Siegfried G. G. Oeljan, Waseca; Dr. John H. Rosenow, Minneapolis; Dr. Melvin Schlemenson, Saint Paul; Dr. Donald E. Stewart, Crookston.

* * *

Dr. A. L. Arends, formerly on the staff of the state hospital at Moose Lake, has opened offices for the practice of medicine in Cokato.

* * *

On November 16, **Dr. C. R. Stanley** of Worthington attended a meeting of the Eye, Ear, Nose and Throat Society of Omaha and Council Bluffs. The meeting was held in Omaha.

* * *

The thirtieth anniversary of the founding of the **Northwestern Clinic** in Crookston was observed on November 11 at the annual dinner for the staff and employes. Fifty-two persons attended, in contrast to the first dinner at which the attendance was five. The clinic was founded thirty years ago by Dr. M. O. Oppegaard, Dr. C. L. Oppegaard and the late Dr. O. E. Locken.

* * *

Dr. Paul F. Brabec, formerly of Forsyth, Montana, has opened offices for the practice of medicine in Detroit Lakes.

* * *

Dr. J. Arthur Myers, professor of medicine, preventive medicine, and public health at the University of Minnesota, was awarded the Hoyt E. Dearholt Medal given annually by the Mississippi Valley Conference on Tuberculosis for outstanding contributions to tuberculosis control. Presentation was made to Dr. Myers at the annual Christmas Seal Dinner of the Minnesota Public Health Association on October 25.

* * *

Dr. Charles W. Fogarty, Jr., of Saint Paul, addressed the Stearns-Benton County Medical Society at St. Cloud on November 16. His subject was "The Use of Cortisone and ACTH in the Treatment of Arthritis."

* * *

The CARE-UNESCO Book Fund celebrated its first anniversary on September 26 by announcing it had received nearly a million dollars in contributions and pledges to provide new books and scientific equipment for educational institutions overseas.

The report showed that 378 educational institutions in twenty-four countries have benefited by deliveries of text and reference works purchased with contributions of various amounts sent to the Book Fund at CARE headquarters, 20 Broad Street, New York City, and local CARE offices throughout the United States, Canada and South America.

Poland and Czechoslovakia closed all CARE service during the year, and deliveries to Korea have had to be suspended because of the military situation. When conditions permit, the Korean operation will be resumed.

Contributions in any amount are accepted by the Book Fund. Sums under $10 are pooled in the general fund. Donors of $10 or more may designate the institution, country and category of book; CARE returns to them a receipt signed by the recipient and, on request, their name is inscribed on the special CARE-UNESCO book plate in each volume. CARE's purchases are based on extensive book lists compiled by a committee of U. S. librarians and scientists headed by Dr. Luther Evans, U. S. Librarian of Congress.

* * *

Dr. Richard Utne of Northfield reported for service at San Antonio, Texas, on November 1.

* * *

Dr. Stewart W. Shimonek, Saint Paul, announces the association of Dr. Mentor H. Christensen in the practice of orthopedic surgery at 942 Lowry Medical Arts Building. Dr. Shiminek has returned temporarily to duty with the United States Navy.

* * *

Dr. Francis J. Savage and Mrs. Mary Watson Blodgett were married on November 1, and are at home at 719 Linwood Avenue, Saint Paul.

* * *

Christmas Seals—Again the Minnesota Public Health Association is conducting its yearly sale of Christmas Seals to assist in the fight against tuberculosis. While each year shows a drop in the tuberculosis death rate in the state, tuberculosis continues to be first as a cause of death in the age group of fifteen to thirty-five.

The funds collected through the sale of seals finance educational programs, make possible tuberculosis testing surveys in our schools and assist in paying for county-wide mass x-ray surveys.

It is imperative that the Christmas Seal Sale be supported each year until tuberculosis is eradicated from the human race.

* * *

Mrs. Donald S. Branham, the wife of Dr. Donald S. Branham, staff member of the St. Peter State Hospital, died in Mankato on October 31.

* * *

Under the teaching grant program, inaugurated two years ago, the **Public Health Service's** National Heart Institute has awarded to date $1,463,814 to forty-nine medical schools in twenty-nine states and the District of Columbia to provide better teaching equipment and wider instruction in heart disease.

Twenty-one new grants plus renewal of forty-four earlier grants, making a total of $855,740, have been approved for mental health research upon recommendation of the National Advisory Mental Health Council of the National Institute of Mental Health, Public Health Service, according to a recent announcement of Oscar R. Ewing. One of the research problems is the attempt to identify the different personality structure of the pre-diabetic. The May Institute for Medical Research, Cincinnati, Ohio, will make a three-year study of the mental, emotional and physical make-up of a selected group of pre-diabetic individuals before these people actually become ill. How this will be accomplished before diabetes develops is not made clear, but doubtless, tax dollars will solve the problem.

One hundred sixty-six grants, totaling $1,915,708 were awarded through the Public Health Service's National Institute of Mental Health to help the expansion of teaching programs in medical schools, universities and other training centers. In addition, an allocation of $1,179,003 will make possible the award of about 560 stipends to graduate students of psychiatry, clinical psychology, psychiatric social work and psychiatric nursing. For these purposes $158,248 goes to the University of Minnesota.

5511 Lyndale Ave. So. LO. 0773 Minneapolis, Minn.

Approximately 250 friends and relatives attended an open house celebration of the golden wedding of **Dr. and Mrs. J. A. Thabes, Sr.,** Brainerd, last month.

Dr. Thabes and his wife are widely known in the Brainerd area for their long and selfless service in community affairs. Dr. Thabes came to Brainerd in 1882 and has practiced medicine in that city for fifty-three years. Dr. Thabes was honored by the Minnesota State Medical association for completing fifty years of service in medicine by being elected to membership in its "Fifty Club" three years ago.

Recently Dr. Thabes was honored by the Elks and Masons for having been an active member of each organization for fifty years. He is a charter member of each. He has just completed serving as chairman of the Crow Wing-Aitkin Sanitorium commission, a position he has held for the past thirty-two years. He has been a member of the Upper Mississippi Medical society for 30 years, since its organization; was president of the State Board of Health for eleven years and has been a member of the American College of Surgeons for thirty years.

Mrs. Thabes has also led an extremely active life, having taught school a number of years, and working along education and health lines. She has served as president of the State Medical auxiliary for many years, and headed the Red Cross in Crow Wing county for thirty years. She has also been a member of the executive committee of the Minnesota Public Health association for twenty-five years, and has the distinction of being the only woman president of that organization, serving as such in 1947 and 1948. She was Republican state chairwoman in 1932-1933.

Dr. Thabes and his wife, among Brainerd's leading citizens, have served the community not only as a doctor and his wife, but have been two of its most public-spirited residents, giving much of their time to working with and for the people of the locality.

HOSPITAL NEWS

Dedication of the new **Ely-Winton Memorial Hospital** took place on November 12. Principal speaker at the dedication of the thirty-five bed hospital was Dr. Vernon D. E. Smith of Saint Paul.

* * *

Dedication services for the new 141-bed addition to **St. Luke's Hospital,** Duluth, were held on November 17. A box filled with articles and information about the hospital, to be "of interest 200 years hence," was sealed in the cornerstone of the addition.

* * *

At a meeting of the commission for the Aitkin-Crow Wing County sanatorium late in October, a resolution was adopted recommending that the **Deerwood Sanatorium** be closed. It was pointed out that modern surgical procedures cannot be carried out in small sanatoriums, and that due to the limited number of patients the cost of running a small institution is proportionately too high. It was stated

that if the patients at Deerwood Sanatorium had been transferred to a large institution, there would have been a saving to the counties of $13,000 last year.

* * *

A new half-million-dollar building at the **Rochester State Hospital** was dedicated on November 2. The structure, which is part of a twenty-two-million-dollar group of buildings being constructed under the new mental health program, will house 150 aged women patients with mental illness. Principal speaker at the dedication ceremonies was Governor Luther Youngdahl. Dr. Magnus C. Petersen is superintendent of the hospital.

* * *

The **Valleyview Hospital**, near Shakopee, opened its doors to patients on November 16. The five buildings comprising the institution have been completely remodeled during the past two years under the supervision of Dr. J. C. Michael, Minneapolis, medical director of the hospital. Forty-four beds were available at the time of opening, but when the main structure is completed, the capacity will be 102 beds. The hospital will care for long-term chronic and convalescent patients.

BLUE CROSS-BLUE SHIELD NEWS

More than 100,000 claims have been adjudicated by Minnesota Medical Service, Inc. This represents something of a milestone in the progress of Blue Shield and bears evidence of our increasing usefulness and value to the contract holder.

Minnesota Blue Shield payments for September, 1950, totaled $231,979.03, providing allowances on 6065 cases covering 27,535 days of hospital care. Of these cases 4576 were for services rendered hospitalized patients; 1465 for office cases and twenty-four for services rendered in the patient's home. Of the total payment for the month, $210,590.91 was for hospitalized cases, $21,069.12 for office cases and $319.00 for home cases. Major surgical procedures totaled 818 representing 7004 days in the amount of $85,282.82; minor procedures totaled 5247, representing 20,531 days' care with payment of $146,696.21.

Payments to participating doctors totaled $220,169.27, representing 3517 surgical cases in the amount of $143,227.67; 1583 medical cases in the amount of $38,517.60, and 720 obstetrical cases in the amount of $38,424.00. Nonparticipating doctors in the state received payment for fifty-eight surgical cases in the amount of $4,347.64; thirty-eight medical cases totaling $960.50 and five obstetrical cases in the amount of $318.00. Out-of-state doctors received payments totaling $6,183.62 covering 144 cases.

Blue Shield enrollment increased during the month to 378,105 participant subscribers; 2001 new Blue Shield contracts became effective. Blue Cross enrollment as of September 30, 1950, totaled 1,027,701.

In order that insofar as possible all 1950 business can be cleared during January, 1951, it is requested that each of you submit claims on any unreported Blue Shield cases. In addition if there are any claims which have been reported prior to October 1, 1950, on which no Blue Shield action has been taken, it is suggested that these cases again be reported, bearing the notation "duplicate."

To enable the Blue Shield office to continue its effective operation, you, the doctor of medicine in Minnesota, can immeasurably assist us by bearing in mind the importance of submitting complete and accurate reports at the earliest opportunity, giving all pertinent information as to the patient, and also the type of service rendered.

In the adjudication and adjustment of Blue Shield claims, Minnesota Medical Service, Inc., is pleased to announce that Dr. Edwin J. Simons, formerly of Swanville, Minnesota, as of November 1, 1950, assumed the position of medical director.

BOOK REVIEW

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical Libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

THE MANAGEMENT OF OBSTETRIC DIFFICULTIES. By Paul Titus, M.D., Obstetrician and Gynecologist to the St. Margaret Memorial Hospital, Pittsburgh; Consulting Obstetrician and Gynecologist to the Shadyside Hospital, Pittsburgh; Secretary of the American Board of Obstetrics and Gynecology; Member Reserve Consultants Advisory Board, Bureau of Medicine and Surgery, United States Navy (Captain, MC, USNR). 4th ed. 1046 pages. Illus. Price $14.00. St. Louis: The C. V. Mosby Company, 1950.

The purpose of this edition, as has been the purpose of the other editions that Titus has written on management of obstetric difficulties, is to provide information that can be made quickly available to aid one's judgment in the proper management of obstetrical problems and emergencies. It is therefore, very useful to the general practitioner as well as the obstetric specialist. Fundamentals and theories have been eliminated to make the material more concise. Emphasis has been placed on diagnosis and treatment. The book covers by sections, the topics on sterility, difficulties in diagnosis of pregnancy, complications of pregnancy, complications of labor, obstetric operation, complications of the puerperium, the newborn infant, special supportive measures.

Many advancements have been made since the third edition was published in 1945. These perhaps can be best summarized in the word of Paul Titus himself in his preface to the fourth edition:

> "New developments in sterility studies and treatment, the current management of threatened and habitual abortions, the changes in management of placenta previa, present views on toxemia of pregnancy, the prevention and management of hemorrhage and shock, are some of the additions in revision. Changes in technique including, induction of labor, preparation for delivery, perineorrhaphy, the management of third stage labor and of retained placenta are described. The chapter on general diseases complicating pregnancy has been added to and revised. The chapter on pelvic mensuration and evaluation by x-ray has been extensively revised and rewritten. New methods of analgesia and anesthesia are discussed."

In an attempt to maintain uniformity of terms before this book was written, a conference was held between Greenhill, Eastman and M. McCormick. Uniform terms were decided upon by these men, and Titus has carried out the use in this edition.

The book is a "must" on the new book list for general practitioners in the country where immediate consultation is not available. It should also be of considerable comfort and interest to the resident staff members to help them in their obstetric problems as they arise. To the specialist it is an important reference book for the unusual complications that arise during pregnancy and labor. The book is well indexed to make the material readily available and also has many references for further study.

Gold has three convictions in the District Court of Hennepin County, Minnesota, for practicing healing without a basic science certificate. He was first convicted May 21, 1946, and placed on probation for one year. In 1948, he was arrested a second time and was sentenced on March 8, that year, to serve one year in the Minneapolis Workhouse. Gold served the entire sentence less time off for good behavior. Gold was convicted a third time in January, 1950. According to Gold's statement, he was born in New York City and worked in a hospital there as an orderly. When he first came to Minneapolis he was, likewise, employed in a hospital in the capacity of an orderly.

Minneapolis Woman Sentenced to Three-year Prison Term for Fraud in Obtaining Narcotic Drugs

Re: United States of America vs. Helen Geneva Rudd.

On November 7, 1950, Mrs. Helen Geneva Rudd, aged fifty-two, 4426 42nd Avenue South, Minneapolis, was sentenced by the Hon. Matthew M. Joyce, Judge of the United States District Court at Minneapolis to three years in a Federal penal type institution. Mrs. Rudd will serve her sentence at the Federal Women's Reformatory at Alderson, West Virginia.

Mrs. Rudd was arrested by Federal narcotic agents on October 17, 1950, following an investigation which disclosed that she had given a false name to a Hennepin County physician in obtaining dilaudid. Mrs. Rudd has a long record of drug addiction. On September 27, 1934, she was given a suspended sentence in the United States District Court at Minneapolis, of eighteen months in a Federal penal institution for violating the Harrison narcotic law. Mrs. Rudd violated her probation and on May 1, 1936, was ordered committed to serve her sentence. Following her release, she was again arrested in July, 1938, for a similar offense, but was acquitted by a jury. In January, 1943, Mrs. Rudd was again arrested for violating the Harrison narcotic act, and on March 2, 1943, entered a plea of guilty at Minneapolis. The charge involved the forging of medical prescriptions. Mrs. Rudd was placed on probation on condition that she take treatment at the Government Hospital at Lexington, Kentucky. She entered the Hospital and was released on March 24, 1945. One week later she was arrested for again attempting to obtain narcotic drugs. Her previous probation was revoked and she was ordered committed to serve her sentence.

In the present case, Mrs. Rudd persuaded a physician to issue fourteen prescriptions for dilaudid and one for codeine in a period of less than one month. The physician who prescribed the narcotic drugs has been ordered to appear before the Minnesota State Board of Medical Examiners at its next regular meeting.

MINNESOTA ACADEMY OF MEDICINE

(Continued from Page 1249)

4. Cases have been mentioned in which variable results are obtained, depending on the stage of the disease or where surgery is still in the experimental stage.
5. Along with this discussion we have presented cases with which we have had personal experience.

Dr. Francis W. Lynch, of Saint Paul, read a paper on "The Quantitative VDRL Test for Syphilis."

The meeting was adjourned.
